Abstract. We generalize the $\Lambda$-adic Shintani lifting for $GL_2(\mathbb{Q})$ to indefinite quaternion algebras over $\mathbb{Q}$.

2010 Mathematics Subject Classification: Primary 11F37, 11F30, 11F85

1. Introduction

Langlands’s principle of functoriality predicts the existence of a staggering wealth of transfers (or lifts) between automorphic forms for different reductive groups. In recent years, attempts at the formulation of $p$-adic variants of Langlands’s functoriality have been articulated in various special cases. We prove the existence of the Shimura-Shintani-Waldspurger lift for $p$-adic families. More precisely, Stevens, building on the work of Hida and Greenberg-Stevens, showed in [21] the existence of a $\Lambda$-adic variant of the classical Shintani lifting of [20] for $GL_2(\mathbb{Q})$. This $\Lambda$-adic lifting can be seen as a formal power series with coefficients in a finite extension of the Iwasawa algebra $\Lambda := \mathbb{Z}_p[[X]]$ equipped with specialization maps interpolating classical Shintani lifts of classical modular forms appearing in a given Hida family.

Shimura in [19], resp. Waldspurger in [22] generalized the classical Shimura-Shintani correspondence to quaternion algebras over $\mathbb{Q}$, resp. over any number field. In the $p$-adic realm, Hida ([7]) constructed a $\Lambda$-adic Shimura lifting, while Ramsey ([17]) (resp. Park [12]) extended the Shimura (resp. Shintani) lifting to the overconvergent setting.

In this paper, motivated by ulterior applications to Shimura curves over $\mathbb{Q}$, we generalize Stevens’s result to any non-split rational indefinite quaternion algebra $B$, building on work of Shimura [19] and combining this with a result of Longo-Vigni [9]. Our main result, for which the reader is referred to Theorem 3.8 below, states the existence of a formal power series and specialization maps interpolating Shimura-Shintani-Waldspurger lifts of classical forms in a given
$p$-adic family of automorphic forms on the quaternion algebra $B$. The $Λ$-adic variant of Waldspurger’s result appears computationally challenging (see remark in [13 Intro.]), but it seems within reach for real quadratic fields (cf. [13]).

As an example of our main result, we consider the case of families with trivial character. Fix a prime number $p$ and a positive integer $N$ such that $p \nmid N$. Embed the set $\mathbb{Z}_{\geq 2}$ of integers greater or equal to 2 in $\text{Hom}(\mathbb{Z}_p^\times, \mathbb{Z}_p^\times)$ by sending $k \in \mathbb{Z}_{\geq 2}$ to the character $x \mapsto x^{k-2}$. Let $f_\infty$ be an Hida family of tame level $N$ passing through a form $f_0$ of level $\Gamma_0(Np)$ and weight $k_0$. There is a neighborhood $U$ of $k_0$ in $\text{Hom}(\mathbb{Z}_p^\times, \mathbb{Z}_p^\times)$ such that, for any $k \in \mathbb{Z}_{\geq 2} \cap U$, the weight $k$ specialization of $f_\infty$ gives rise to an element $f_k \in S_k(\Gamma_0(Np))$.

Fix a factorization $N = MD$ with $D > 1$ a square-free product of an even number of primes and $\gcd(M, D) = 1$ (we assume that such a factorization exists). Applying the Jacquet-Langlands correspondence we get for any $k \in \mathbb{Z}_{\geq 2} \cap U$ a modular form $f_k^{\text{JL}}$ on $\Gamma$, which is the group of norm-one elements in an Eichler order $R$ of level $Mp$ contained in the indefinite rational quaternion algebra $B$ of discriminant $D$. One can show that these modular forms can be $p$-adically interpolated, up to scaling, in a neighborhood of $k_0$. More precisely, let $\mathcal{O}$ be the ring of integers of a finite extension $F$ of $\mathbb{Q}_p$ and let $D$ denote the $\mathcal{O}$-module of $\mathcal{O}$-valued measures on $\mathbb{Z}_p^2$ which are supported on the set of primitive elements in $\mathbb{Z}_p^2$. Let $\Gamma_0$ be the group of norm-one elements in an Eichler order $R_0 \subseteq B$ containing $R$. There is a canonical action of $\Gamma_0$ on $D$ (see [9, §2.4] for its description). Denote by $F_k$ the extension of $F$ generated by the Fourier coefficients of $f_k$. Then there is an element $\Phi \in H^1(\Gamma_0, D)$ and maps $\rho_k : H^1(\Gamma_0, D) \rightarrow H^1(\Gamma, F_k)$ such that $\rho(k)(\Phi) = \phi_k$, the cohomology class associated to $f_k^{\text{JL}}$, with $k$ in a neighborhood of $k_0$ (for this we need a suitable normalization of the cohomology class associated to $f_k^{\text{JL}}$, which we do not touch for simplicity in this introduction). We view $\Phi$ as a quaternionic family of modular forms. To each $\phi_k$ we may apply the Shimura-Shintani-Waldspurger lifting ([13]) and obtain a modular form $h_k$ of weight $k + 1/2$, level $4Np$ and trivial character. We show that this collection of forms can be $p$-adically interpolated. For clarity’s sake, we present the liftings and their $Λ$-adic variants in a diagram, in which the horizontal maps are specialization maps of the $p$-adic family to weight $k$; $\text{JL}$ stands for the Jacquet-Langlands correspondence; $\text{SSW}$ stands for the Shimura-Shintani-Waldspurger lift; and the dotted arrows are constructed in this paper:
More precisely, as a particular case of our main result, Theorem 3.8, we get the following

**Theorem 1.1.** There exists a $p$-adic neighborhood $U_0$ of $k_0$ in $\text{Hom}(\mathbb{Z}_p^\times, \mathbb{Z}_p^\times)$, $p$-adic periods $\Omega_k$ for $k \in U_0 \cap \mathbb{Z}^{\geq 2}$ and a formal expansion

$$\Theta = \sum_{\xi \geq 1} a_\xi q^\xi$$

with coefficients $a_\xi$ in the ring of $\mathbb{C}_p$-valued functions on $U_0$, such that for all $k \in U_0 \cap \mathbb{Z}^{\geq 2}$ we have

$$\Theta(k) = \Omega_k \cdot h_k.$$

Further, $\Omega_{k_0} \neq 0$.

2. **Shintani integrals and Fourier coefficients of half-integral weight modular forms**

We express the Fourier coefficients of half-integral weight modular forms in terms of period integrals, thus allowing a cohomological interpretation which is key to the production of the $\Lambda$-adic version of the Shimura-Shintani-Waldspurger correspondence. For the quaternionic Shimura-Shintani-Waldspurger correspondence of interest to us (see [15], [22]), the period integrals expressing the values of the Fourier coefficients have been computed generally by Prasanna in [16].

2.1. **The Shimura-Shintani-Waldspurger lifting.** Let $4M$ be a positive integer, $2k$ an even non-negative integer and $\chi$ a Dirichlet character modulo $4M$ such that $\chi(-1) = 1$. Recall that the space of half-integral weight modular forms $\mathcal{S}_{k+1/2}(4M, \chi)$ consists of holomorphic cuspidal functions $h$ on the upper-half place $\mathcal{H}$ such that

$$h(\gamma(z)) = j^{1/2}(\gamma, z)^{2k+1}\chi(d)h(z),$$

for all $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(4M)$, where $j^{1/2}(\gamma, z)$ is the standard square root of the usual automorphy factor $j(\gamma, z)$ (cf. [15, 2.3]).

To any quaternionic integral weight modular form we may associate a half-integral weight modular form following Shimura’s work [19], as we will describe below.

Fix an odd square free integer $N$ and a factorization $N = M \cdot D$ into coprime integers such that $D > 1$ is a product of an even number of distinct primes. Fix a Dirichlet character $\psi$ modulo $M$ and a positive even integer $2k$. Suppose that

$$\psi(-1) = (-1)^k.$$ 

Define the Dirichlet character $\chi$ modulo $4N$ by

$$\chi(x) := \psi(x) \left( \frac{-1}{x} \right)^k .$$
Let $B$ be an indefinite quaternion algebra over $\mathbb{Q}$ of discriminant $D$. Fix a maximal order $\mathcal{O}_B$ of $B$. For every prime $\ell | M$, choose an isomorphism

$$i_\ell : B \otimes \mathbb{Q}_\ell \simeq M_2(\mathbb{Q}_\ell)$$

such that $i_\ell(\mathcal{O}_B \otimes \mathbb{Z}_\ell) = M_2(\mathbb{Z}_\ell)$. Let $R \subseteq \mathcal{O}_B$ be the Eichler order of $B$ of level $M$ defined by requiring that $i_\ell(R \otimes \mathbb{Z}_\ell)$ is the suborder of $M_2(\mathbb{Z}_\ell)$ of upper triangular matrices modulo $\ell$ for all $\ell | M$. Let $\Gamma$ denote the subgroup of the group $R_1^\ast$ of norm 1 elements in $R^\ast$ consisting of those $\gamma$ such that $i_\ell(\gamma) \equiv \left( \begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix} \right)$ mod $\ell$ for all $\ell | M$. We denote by $S_{2k}(\Gamma)$ the $\mathbb{C}$-vector space of weight $2k$ modular forms on $\Gamma$, and by $S_{2k}(\Gamma, \psi^2)$ the subspace of $S_{2k}(\Gamma)$ consisting of forms having character $\psi^2$ under the action of $R_1^\ast$. Fix a Hecke eigenform

$$f \in S_{2k}(\Gamma, \psi^2)$$

as in [19, Section 3].

Let $V$ denote the $\mathbb{Q}$-subspace of $B$ consisting of elements with trace equal to zero. For any $v \in V$, which we view as a trace zero matrix in $M_2(\mathbb{R})$ (after fixing an isomorphism $i_\infty : B \otimes \mathbb{R} \simeq M_2(\mathbb{R})$), set

$$G_v := \{ \gamma \in SL_2(\mathbb{R}) | \gamma^{-1} v \gamma = v \}$$

and put $\Gamma_v := G_v \cap \Gamma$. One can show that there exists an isomorphism

$$\omega : \mathbb{R}^\times \xrightarrow{\sim} G_v$$

defined by $\omega(s) = \beta^{-1} \left( \begin{smallmatrix} s & 0 \\ 0 & 1/s \end{smallmatrix} \right) \beta$, for some $\beta \in SL_2(\mathbb{R})$. Let $t_v$ be the order of $\Gamma_v \cap \{ \pm 1 \}$ and let $\gamma_v$ be an element of $\Gamma_v$ which generates $\Gamma_v \{ \pm 1 \} / \{ \pm 1 \}$. Changing $\gamma_v$ to $\gamma_v^{-1}$ if necessary, we may assume $\gamma_v = \omega(t)$ with $t > 0$. Define $V^\ast$ to be the $\mathbb{Q}$-subspace of $V$ consisting of elements with strictly negative norm. For any $\alpha = \left( \begin{smallmatrix} a & b \\ c & -a \end{smallmatrix} \right) \in V^\ast$ and $z \in \mathcal{H}$, define the quadratic form

$$Q_\alpha(z) := cz^2 - 2az - b.$$ 

Fix $\tau \in \mathcal{H}$ and set

$$P(f, \alpha, \Gamma) := -\left(2(\text{nr}(\alpha))^{1/2}/t_v\right) \int_{\tau}^{\gamma_v(\tau)} Q_\alpha(z)^{k-1} f(z) dz$$

where $\text{nr} : B \to \mathbb{Q}$ is the norm map. By [19, Lemma 2.1], the integral is independent on the choice $\tau$, which justifies the notation.

**Remark 2.1.** The definition of $P(f, \alpha, \Gamma)$ given in [19, (2.5)] looks different: the above expression can be derived as in [19, page 629] by means of [19, (2.20) and (2.22)].

Let $R(\Gamma)$ denote the set of equivalence classes of $V^\ast$ under the action of $\Gamma$ by conjugation. By [19, (2.6)], $P(f, \alpha, \Gamma)$ only depends on the conjugacy class of $\alpha$, and thus, for $C \in R(\Gamma)$, we may define $P(f, C, \Gamma) := P(f, \alpha, \Gamma)$ for any choice of $\alpha \in C$. Also, $q(C) := \text{nr}(\alpha)$ for any $\alpha \in C$.

Define $\mathcal{O}_B'$ to be the maximal order in $B$ such that $\mathcal{O}_B' \otimes \mathbb{Z}_\ell \simeq \mathcal{O}_B \otimes \mathbb{Z}_\ell$ for all $\ell \nmid M$ and $\mathcal{O}_B' \otimes \mathbb{Z}_\ell$ is equal to the local order of $B \otimes \mathbb{Q}_\ell$ consisting of
Define a locally constant function \( H \) is an Hecke pair, we let 

\[
\gamma \quad \text{define the action of the Hecke action on cohomology groups; for details, see [9, 2.2.].}
\]

Then, by [19, Theorem 3.1],

\[
\text{for any } C \in R(\Gamma), \text{ fix } \alpha C \in C. \text{ For any integer } \xi \geq 1, \text{ define}
\]

\[
a_\xi(h) := (2\mu(\Gamma \backslash \delta))^{-1} \cdot \sum_{C \in R(\Gamma) \mid q(C) = \xi} \eta_0(\alpha C) \xi^{-1/2} P(f, C, \Gamma).
\]

Then, by [19 Theorem 3.1],

\[
\tilde{h} := \sum_{\xi \geq 1} a_\xi(h) \xi^\ell \in S_{k+1/2}(\Gamma_1, \chi)
\]

is called the Shimura-Shintani-Waldspurger lifting of \( f \).

2.2. Cohomological interpretation. We introduce necessary notation to define the action of the Hecke algebra on cohomology groups; for details, see [9 §2.1]. If \( G \) is a subgroup of \( B^\times \) and \( S \) a subsemigroup of \( B^\times \) such that \((G, S)\) is an Hecke pair, we let \( \mathcal{H}(G, S) \) denote the Hecke algebra corresponding to \((G, S), \) whose elements are written as \( T(s) = GsG = \prod_i Gs_i \) for \( s, s_i \in S \) (finite disjoint union). For any \( s \in S, \) let \( s^* := \text{norm}(s)s^{-1} \) and denote by \( S^* \) the set of elements of the form \( s^* \) for \( s \in S. \) For any \( \mathbb{Z}[S^*]-\text{module } M \) we let \( T(s) \) act on \( H^1(G, M) \) at the level of cochains \( c \in Z^1(G, M) \) by the formula \( (c|T(s)) (\gamma) = \sum_i s_i^* c(t_i(\gamma)) \), where \( t_i(\gamma) \) are defined by the equations \( Gs_i \gamma = Gs_j \) and \( s_i \gamma = t_i(\gamma) s_j. \) In the following, we will consider the case of \( G = \Gamma \) and

\[
S = \{ s \in B^\times | \text{iq}(s) \text{ is congruent to } (1,1) \text{ mod } \ell \text{ for all } \ell | M \}.
\]

For any field \( L \) and any integer \( n \geq 0, \) let \( V_n(L) \) denote the \( L \)-dual of the \( L \)-vector space \( P_n(L) \) of homogeneous polynomials in 2 variables of degree \( n. \) We let \( \mathcal{H}_2(L) \) act from the right on \( P(x, y) \) as \( P|\gamma(x, y) := P(\gamma(x, y)) \), where for \( \gamma = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \) we put

\[
\gamma(x, y) := (ax + by, cx + dy).
\]

This also equips \( V_n(L) \) with a left action by \( \gamma : \varphi \mapsto \varphi(\gamma). \) To simplify the notation, we will write \( P(\gamma(z)) \) for \( P(\gamma, 1). \)

Let \( F \) denote the finite extension of \( \mathbb{Q} \) generated by the eigenvalues of the Hecke action on \( f. \) For any field \( K \) containing \( F, \) set

\[
\mathcal{W}_f(K) := H^1(\Gamma, V_{k-2}(K))^f
\]

where the superscript \( f \) denotes the subspace on which the Hecke algebra acts via the character associated with \( f. \) Also, for any sign \( \pm, \) let \( \mathcal{W}_f^\pm(K) \) denote the \( \pm \)-eigenspace for the action of the archimedean involution \( \iota. \) Remember that \( \iota \) is defined by choosing an element \( \omega_\infty \) of norm \(-1 \) in \( R^\times \) such that such
that $i_\ell (\omega_\infty) \equiv \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ mod $M$ for all primes $\ell | M$ and then setting $\iota := T(w_\infty)$ (see [9, §2.1]). Then $W_f^\infty(K)$ is one dimensional (see, e.g., [9] Proposition 2.2); fix a generator $\phi_f^\pm$ of $W_f^\infty(F)$.

To explicitly describe $\phi_f^\pm$, let us introduce some more notation. Define

$$f|_{\omega_\infty}(z) := (Cz + D)^{-k/2}f(\omega_\infty(z))$$

where $i_\infty(\omega_\infty) = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$. Then $f|_{\omega_\infty} \in S_{2k}(\Gamma)$ as well. If the eigenvalues of the Hecke action on $f$ are real, then we may assume, after multiplying $f$ by a scalar, that $f|_{\omega_\infty} = f$ (see [19, p. 627] or [10, Lemma 4.15]). In general, let $I(f)$ denote the class in $H^1(\Gamma, V_{k-2}(\mathbb{C}))$ represented by the cocycle

$$\gamma \mapsto \left[ P \mapsto I_\gamma(f)(P) := \int_\gamma \frac{f(z)}{P(z)} dz \right]$$

for any $\tau \in \mathcal{H}$ (the corresponding class is independent on the choice of $\tau$). With this notation,

$$P(f, \alpha, \Gamma) = -(2(-n(r(\alpha))^{1/2}/\kappa_n) \cdot I_{\gamma_n}(f)(Q_{\alpha_n}(z)^{k-1}).$$

Denote by $I^\pm(f) := (1/2) \cdot I(f) \pm (1/2) \cdot I(f)|\omega_\infty$, the projection of $I(f)$ to the eigenspaces for the action of $\omega_\infty$. Then $I(f) = I^+(f) + I^-(f)$ and $I_f^\pm = \Omega_f^\pm \cdot \phi_f^\pm$, for some $\Omega_f^\pm \in \mathbb{C}^\times$.

Given $\alpha \in V^\times$ of norm $-\xi$, put $\alpha' := \omega_\infty^{-1} \omega_\infty$. By [19, 4.19], we have

$$\eta(\alpha)\xi^{-1/2}P(f, \alpha, \Gamma) + \eta(\alpha')\xi^{-1/2}P(f, \alpha', \Gamma) = -\eta(\alpha) \cdot t_{\alpha_1}^{-1} \cdot I_{\gamma_1}^+(Q_{\alpha_1}(z)^{k-1}).$$

We then have

$$a_\xi(\tilde{h}) = \sum_{c \in R_{\Gamma}(\Gamma), q(c) = \xi} \frac{-\eta(\alpha)}{2\mu(\Gamma \setminus \mathcal{H}) \cdot t_{\alpha}} \cdot I_{\gamma_n}^+(Q_{\alpha_1}(z)^{k-1}).$$

We close this section by choosing a suitable multiple of $h$ which will be the object of the next section. Given $Q_\alpha(z) = cz^2 - 2az - b$ as above, with $\alpha$ in $V^\times$, define $Q_\alpha(z) := M \cdot Q_\alpha(z)$. Then, clearly, $I^{k}(f)(Q_{\alpha_1}(z)^{k-1})$ is equal to $M^{k-1}I^{k}(f)(Q_{\alpha_1}(z)^{k-1})$. We thus normalize the Fourier coefficients by setting

$$a_\xi(h) := \frac{a_\xi(\tilde{h}) \cdot M^{k-1} \cdot 2\mu(\Gamma \setminus \mathcal{H})}{\Omega_f^\pm} = \sum_{c \in R(\Gamma, q(c) = \xi)} \eta(\alpha) \cdot t_{\alpha} \cdot \phi_f^\pm (Q_{\alpha_1}(z)^{k-1}).$$

So

$$h := \sum_{\xi \geq 1} a_\xi(h) q^\xi$$

belongs to $S_{k+1/2}(4N, \chi)$ and is a non-zero multiple of $\tilde{h}$. 

Documenta Mathematica 18 (2013) 1–21.
3. THE $\Lambda$-ADIC SHIMURA-SHINTANI-WALDSPURGER CORRESPONDENCE

At the heart of Stevens’s proof lies the control theorem of Greenberg-Stevens, which has been worked out in the quaternionic setting by Longo–Vigni [9]. Recall that $N \geq 1$ is a square free integer and fix a decomposition $N = M \cdot D$ where $D$ is a square free product of an even number of primes and $M$ is coprime to $D$. Let $p \nmid N$ be a prime number and fix an embedding $\overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}}_p$.

3.1. THE HIDA HECKE ALGEBRA. Fix an ordinary $p$-stabilized newform

$$f_0 \in S_{k_0}(\Gamma_1(Mp^{\infty}) \cap \Gamma_0(D), \epsilon_0)$$

of level $\Gamma_1(Mp^{\infty}) \cap \Gamma_0(D)$, Dirichlet character $\epsilon_0$ and weight $k_0$, and write $\mathcal{O}$ for the ring of integers of the field generated over $\mathbb{Q}_p$ by the Fourier coefficients of $f_0$.

Let $\Lambda$ (respectively, $\mathcal{O}[[\mathbb{Z}_p^n]]$) denote the Iwasawa algebra of $W := 1 + p\mathbb{Z}_p$ (respectively, $\mathbb{Z}_p^n$) with coefficients in $\mathcal{O}$. We denote group-like elements in $\Lambda$ and $\mathcal{O}[[\mathbb{Z}_p^n]]$ as $[t]$. Let $\mathfrak{h}_{\infty}^\text{rd}$ denote the $p$-ordinary Hida Hecke algebra with coefficients in $\mathcal{O}$ of tame level $\Gamma_1(N)$. Denote by $\mathcal{L} := \text{Frac}(\Lambda)$ the fraction field of $\Lambda$. Let $\mathcal{R}$ denote the integral closure of $\Lambda$ in the primitive component $\mathcal{K}$ of $\mathfrak{h}_{\infty}^\text{rd} \otimes_\Lambda \mathcal{L}$ corresponding to $f_0$. It is well known that the $\Lambda$-algebra $\mathcal{R}$ is finitely generated as $\Lambda$-module.

Denote by $\mathcal{X}$ the $\mathcal{O}$-module $\text{Hom}^\text{cont}_{\mathcal{O}_\text{alg}}(\mathcal{R}, \overline{\mathbb{Q}}_p)$ of continuous homomorphisms of $\mathcal{O}$-algebras. Let $\mathcal{X}_\text{arithmetic}$ be the set of arithmetic homomorphisms in $\mathcal{X}$, defined in [9] [2.2] by requiring that the composition

$$W \longrightarrow \Lambda \longrightarrow \overline{\mathbb{Q}}_p$$

has the form $\gamma \mapsto \psi_\kappa(\gamma)\gamma^{n_\kappa}$ for an integer $k_\kappa \geq 2$ (called the weight of $\kappa$) and a finite order character $\psi_\kappa : W \rightarrow \overline{\mathbb{Q}}_p$ (called the wild character of $\kappa$). Denote by $r_\kappa$ the smallest among the positive integers $t$ such that $1 + p^t \mathbb{Z}_p \subseteq \ker(\psi_\kappa)$. For any $\kappa \in \mathcal{X}_\text{arithmetic}$, let $P_\kappa$ denote the kernel of $\kappa$ and $\mathcal{R}_{P_\kappa}$ the localization of $\mathcal{R}$ at $\kappa$. The field $F_\kappa := \mathcal{R}_{P_\kappa}/P_\kappa\mathcal{R}_{P_\kappa}$ is a finite extension of $\text{Frac}(\mathcal{O})$. Further, by duality, $\kappa$ corresponds to a normalized eigenform

$$f_\kappa \in S_{k_\kappa}(\Gamma_0(Np^{\infty}), \epsilon_{k_\kappa})$$

for a Dirichlet character $\epsilon_{k_\kappa} : (\mathbb{Z}/Np^{\infty}\mathbb{Z})^\times \rightarrow \overline{\mathbb{Q}}_p$. More precisely, if we write $\psi_\mathcal{R}$ for the character of $\mathcal{R}$, defined as in [9] Terminology p. 555], and we let $\omega$ denote the Teichmüller character, we have $\epsilon_{k_\kappa} := \psi_{k_\kappa} \cdot \psi_{\mathcal{R}} \cdot \omega^{-n_\kappa}$ (see [9] Cor. 1.6]). We call $(\epsilon_{k_\kappa}, k_\kappa)$ the signature of $\kappa$. We let $k_0$ denote the arithmetic character associated with $f_0$, so $f_0 = f_{k_0}$, $k_0 = k_{k_\kappa}$, $\epsilon_0 = \epsilon_{k_\kappa}$, and $r_0 = r_{k_0}$. The eigenvalues of $f_\kappa$ under the action of the Hecke operators $T_n$ ($n \geq 1$ an integer) belong to $F_\kappa$. Actually, one can show that $f_\kappa$ is a $p$-stabilized newform on $\Gamma_1(Mp^{\infty}) \cap \Gamma_0(D)$.

Let $\Lambda_N$ denote the Iwasawa algebra of $\mathbb{Z}_p^n \times (\mathbb{Z}/N\mathbb{Z})^\times$ with coefficients in $\mathcal{O}$. To simplify the notation, define $\Delta := (\mathbb{Z}/Np\mathbb{Z})^\times$. We have a canonical isomorphism of rings $\Lambda_N \simeq \Lambda[\Delta]$, which makes $\Lambda_N$ a $\Lambda$-algebra, finitely generated as
\(\Lambda\)-module. Define the tensor product of \(\Lambda\)-algebras
\[
\mathcal{R}_N := \mathcal{R} \otimes_{\Lambda} \Lambda_N,
\]
which is again a \(\Lambda\)-algebra (resp. \(\Lambda_N\)-algebra) finitely generated as a \(\Lambda\)-module, (resp. as a \(\Lambda_N\)-module). One easily checks that there is a canonical isomorphism of \(\Lambda\)-algebras
\[
\mathcal{R}_N \simeq \mathcal{R}[\Delta]
\]
(where \(\Lambda\) acts on \(\mathcal{R}\)); this is also an isomorphism of \(\Lambda_N\)-algebras, when we let \(\Lambda_N \simeq \Lambda[\Delta]\) act on \(\mathcal{R}[\Delta]\) in the obvious way.

We can extend any \(\kappa \in \mathcal{X}^{\text{arith}}\) to a continuous \(\mathcal{O}\)-algebra morphism
\[
\kappa_N : \mathcal{R}_N \longrightarrow \bar{\mathbb{Q}}_p
\]
setting
\[
\kappa_N \left( \sum_{i=1}^{n} r_i \cdot \delta_i \right) := \sum_{i=1}^{n} \kappa(r_i) \cdot \psi_R(\delta_i)
\]
for \(r_i \in \mathcal{R}\) and \(\delta_i \in \Delta\). Therefore, \(\kappa_N\) restricted to \(\mathbb{Z}_p^\times\) is the character \(t \mapsto \epsilon_\kappa(t) t^{n_\kappa}\). If we denote by \(\mathcal{X}_N\) the \(\mathcal{O}\)-module of continuous \(\mathcal{O}\)-algebra homomorphisms from \(\mathcal{R}_N\) to \(\bar{\mathbb{Q}}_p\), the above correspondence sets up an injective map \(\mathcal{X}^{\text{arith}} \hookrightarrow \mathcal{X}_N\). Let \(\mathcal{X}_N^{\text{arith}}\) denote the image of \(\mathcal{X}^{\text{arith}}\) under this map. For \(\kappa_N \in \mathcal{X}_N^{\text{arith}}\), we define the signature of \(\kappa_N\) to be that of the corresponding \(\kappa\).

3.2. The control theorem in the quaternionic setting. Recall that \(B/\mathbb{Q}\) is a quaternion algebra of discriminant \(D\). Fix an auxiliary real quadratic field \(F\) such that all primes dividing \(D\) are inert in \(F\) and all primes dividing \(Mp\) are split in \(F\), and an isomorphism \(i_F : B \otimes_{\mathbb{Q}} F \simeq M_2(F)\). Let \(\mathcal{O}_B\) denote the maximal order of \(B\) obtained by taking the intersection of \(B\) with \(M_2(\mathcal{O}_F)\), where \(\mathcal{O}_F\) is the ring of integers of \(F\). More precisely, define
\[
\mathcal{O}_B := \iota^{-1}(i_F^{-1}(i_F(B \otimes 1) \cap M_2(\mathcal{O}_F)))
\]
where \(\iota : B \hookrightarrow B \otimes_{\mathbb{Q}} F\) is the inclusion defined by \(b \mapsto b \otimes 1\). This is a maximal order in \(B\) because \(i_F(B \otimes 1) \cap M_2(\mathcal{O}_F)\) is a maximal order in \(i_F(B \otimes 1)\). In particular, \(i_F\) and our fixed embedding of \(\bar{\mathbb{Q}}\) into \(\bar{\mathbb{Q}}_p\) induce an isomorphism
\[
i_p : B \otimes_{\mathbb{Q}} \mathbb{Q}_p \simeq M_2(\mathbb{Q}_p)
\]
such that \(i_p(\mathcal{O}_B \otimes_{\mathbb{Z}} \mathbb{Z}_p) = M_2(\mathbb{Z}_p)\). For any prime \(\ell|M\), also choose an embedding \(\mathbb{Q} \hookrightarrow \mathbb{Q}_\ell\) which, composed with \(i_F\), yields isomorphisms
\[
i_\ell : B \otimes_{\mathbb{Q}} \mathbb{Q}_\ell \simeq M_2(\mathbb{Q}_\ell)
\]
such that \(i_p(\mathcal{O}_B \otimes_{\mathbb{Z}} \mathbb{Z}_\ell) = M_2(\mathbb{Z}_\ell)\). Define an Eichler order \(R \subseteq \mathcal{O}_B\) of level \(M\) by requiring that for all primes \(\ell|M\) the image of \(R \otimes_{\mathbb{Z}} \mathbb{Z}_\ell\) via \(i_\ell\) consists of upper triangular matrices modulo \(\ell\). For any \(r \geq 0\), let \(\Gamma_r\) denote the subgroup of the group \(\mathbb{R}^*_+\) of norm-one elements in \(R\) consisting of those \(\gamma\) such that \(i_\ell(\gamma) = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right)\) with \(c \equiv 0 \mod Mp\) and \(a \equiv d \equiv 1 \mod Mp\).
for all primes $\ell | M_p$. To conclude this list of notation and definitions, fix an embedding $F \hookrightarrow \mathbb{R}$ and let $i_\infty : B \otimes_{\mathbb{Q}} \mathbb{R} \simeq M_2(\mathbb{R})$ be the induced isomorphism.

Let $Y := \mathbb{Z}_p^2$ and denote by $X$ the set of primitive vectors in $Y$. Let $D$ denote the $O$-module of $O$-valued measures on $Y$ which are supported on $X$. Note that $M_2(\mathbb{Z}_p)$ acts on $Y$ by left multiplication; this induces an action of $M_2(\mathbb{Z}_p)$ on the $O$-module of $O$-valued measures on $Y$, which induces an action on $D$. The group $R^\times$ acts on $D$ via $i_\infty$. In particular, we may define the group:

$$W := H^1(\Gamma_0, D).$$

Then $D$ has a canonical structure of $O[\mathbb{Z}_p^\times]$-module, as well as $K_{2d}$-action, as described in [9 §2.4]. In particular, let us recall that, for any $[t] \in O[\mathbb{Z}_p^\times]$, we have

$$\int_X \varphi(x, y) d([t] \cdot \nu) = \int_X \varphi(tx, ty) d\nu,$$

for any locally constant function $\varphi$ on $X$.

For any $\kappa \in X_{\text{arith}}$ and any sign $\pm \in \{-, +\}$, set

$$W^\pm_\kappa := W^\pm_{f_{\kappa}}(F_\kappa) = H^1(\Gamma_{\kappa}, V_{n_\kappa}(F_\kappa))^{f_{\kappa}, \pm}$$

where $f_{\kappa}$ is any Jacquet-Langlands lift of $f_\kappa$ to $\Gamma_{\kappa}$; recall that the superscript $f_\kappa$ denotes the subspace on which the Hecke algebra acts via the character associated with $f_\kappa$, and the superscript $\pm$ denotes the $\pm$-eigenspace for the action of the archimedean involution $\iota$. Also, recall that $W^\pm_\kappa$ is one dimensional and fix a generator $\phi^\pm_\kappa$ of it.

We may define specialization maps

$$\rho_\kappa : \mathbb{D} \rightarrow V_{n_\kappa}(F_\kappa)$$

by the formula

$$\rho_\kappa(\nu)(P) := \int_{\mathbb{Z}_p \times \mathbb{Z}_p^\times} e_\kappa(y) P(x, y) d\nu$$

which induces (see [9 §2.5]) a map:

$$\rho_\kappa : \mathbb{W} \rightarrow \mathbb{W}_\kappa.$$

Here $\mathbb{W}$ and $\mathbb{W}_\kappa$ denote the ordinary submodules of $\mathbb{W}$ and $\mathbb{W}_\kappa$, respectively, defined as in [3 Definition 2.2] (see also [9 §3.5]). We also let $\mathbb{W}_R := \mathbb{W} \otimes_{\Lambda} \mathbb{R}$, and extend the above map $\rho_\kappa$ to a map

$$\rho_\kappa : \mathbb{W}_R \rightarrow \mathbb{W}_\kappa$$

by setting $\rho_\kappa(x \otimes r) := \rho_\kappa(x) \cdot \kappa(r)$.

**Theorem 3.1.** There exists a $p$-adic neighborhood $U_0$ of $\kappa_0$ in $X$, elements $\Phi^\pm$ in $\mathbb{W}_R^\text{ord}$ and choices of $p$-adic periods $\Omega^\pm_\kappa \in F_\kappa$ for $\kappa \in U_0 \cap X_{\text{arith}}$ such that, for all $\kappa \in U_0 \cap X_{\text{arith}}$, we have

$$\rho_\kappa(\Phi^\pm) = \Omega^\pm_\kappa \cdot \phi^\pm_\kappa.$$
and $\Omega_{\kappa_0} \neq 0$.

**Proof.** This is an easy consequence of [9, Theorem 2.18] and follows along the lines of the proof of [21, Theorem 5.5], cf. [10, Proposition 3.2]. □

We now normalize our choices as follows. With $U_0$ as above, define

$$U_0^\text{arith} := U_0 \cap \mathcal{X}_0^\text{arith}.$$ 

Fix $\kappa \in U_0^\text{arith}$ and an embedding $\bar{Q}_p \hookrightarrow \mathbb{C}$. Let $f^\text{HL}_\kappa$ denote a modular form on $\Gamma_{r,\kappa}$, corresponding to $f_\kappa$ by the Jacquet-Langlands correspondence, which is well defined up to elements in $\Lambda \widehat{\otimes} \mathbb{C}$. View $\Phi_{\pm,\kappa}$ as an element in $H^1(\Gamma_{r,\kappa}, V^\kappa_{\text{fl}}(\mathbb{C}))_\pm$.

Choose a representative $\Phi_{\pm,\gamma}$ of $\Phi_{\pm,\kappa}$, by which we mean that if $\Phi_{\pm,\kappa} = \sum_i \Phi_{\pm,\gamma} \otimes r_i$, then we choose a representative $\Phi_{\pm,\gamma}$ for all $i$. Also, we will write $\rho_{\kappa}(\Phi)(P) := \int_{\mathbb{Z}_p \times \mathbb{Z}_p} \epsilon_\kappa(y) P(x, y) d\Phi_{\pm,\gamma}(x, y)$.

With this notation, we see that the two cohomology classes $\gamma \mapsto \int_{\mathbb{Z}_p \times \mathbb{Z}_p} \epsilon_\kappa(y) P(x, y) d\Phi_{\pm,\gamma}(x, y)$ and $\gamma \mapsto \Omega_{\kappa}^\pm \cdot \int_{\mathbb{Z}_p} \psi_{\kappa}(\gamma) \cdot \int_{\mathbb{Z}_p} P(z, 1) f^\text{HL}_{\kappa,\gamma}(z) dz$ are cohomologous in $H^1(\Gamma_{r,\kappa}, V_{\text{fl}}^\kappa(\mathbb{C}))$, for any choice of $\tau \in \mathcal{H}$.

### 3.3. Metaplectic Hida Hecke algebras

Let $\sigma : \Lambda_N \to \Lambda_N$ be the ring homomorphism associated to the group homomorphism $t \mapsto t^2$ on $\mathbb{Z}_p^\times \times (\mathbb{Z}/N\mathbb{Z})^\times$, and denote by the same symbol its restriction to $\Lambda$ and $\mathcal{O}[\mathbb{Z}_p^\times]$. We let $\Lambda_{\sigma}$, $\mathcal{O}[\mathbb{Z}_p^\times]$, and $\Lambda_{N,\sigma}$ denote, respectively, $\Lambda$, $\mathcal{O}[\mathbb{Z}_p^\times]$ and $\Lambda_N$ viewed as algebras over themselves via $\sigma$. The ordinary metaplectic $p$-adic Hida Hecke algebra we will consider is the $\Lambda$-algebra $\widetilde{R} := R \otimes_{\Lambda} \Lambda_{\sigma}$.

Define as above

$$\tilde{X} := \text{Hom}_{\mathcal{O}_{\text{alg}}}(\tilde{R}, \bar{Q}_p)$$

and let the set $\tilde{X}^\text{arith}$ of arithmetic points in $\tilde{X}$ to consist of those $\tilde{\kappa}$ such that the composition

$$W^\kappa \xrightarrow{\Lambda_{r,\kappa}} \Lambda_{r,\kappa+1,\kappa} \xrightarrow{\Lambda_{r,\kappa}} \tilde{R} \xrightarrow{\psi_{\kappa}} \bar{Q}_p$$

has the form $\gamma \mapsto \psi_{\kappa}(\gamma) \gamma^{n_{\kappa}}$ with $n_{\kappa} := k_{\bar{\kappa}} - 2$ for an integer $k_{\bar{\kappa}} \geq 2$ (called the weight of $\bar{\kappa}$) and a finite order character $\psi_{\kappa} : W \to \bar{Q}$ (called the wild character of $\bar{\kappa}$). Let $r_{\kappa}$ the smallest among the positive integers $t$ such that $1 + p^t \mathbb{Z}_p \subseteq \ker(\psi_{\kappa})$.

We have a map $p : \tilde{X} \to X$ induced by pull-back from the canonical map $R \to \tilde{R}$. The map $p$ restricts to arithmetic points.
As above, define the $\Lambda$-algebra (or $\Lambda_N$-algebra)

$$\tilde{\mathcal{R}}_N := \mathcal{R} \otimes_{\Lambda} \Lambda_N, \sigma$$

via $\lambda \mapsto 1 \otimes \lambda$.

We easily see that $\tilde{\mathcal{R}}_N \simeq \tilde{\mathcal{R}}[\Delta]$ as $\Lambda_N$-algebras, where we enhance $\tilde{\mathcal{R}}[\Delta]$ with the following structure of $\Lambda_N$-algebra: for $\sum_i \lambda_i \cdot \delta_i \in \tilde{\mathcal{R}}[\Delta]$ (with $\lambda_i \in \Lambda$ and $\delta_i \in \Delta$) and $\sum_j r_j \cdot \delta'_j \in \tilde{\mathcal{R}}[\Delta]$ (with $r_j = \sum_h r_{j,h} \otimes \lambda_{j,h} \in \tilde{\mathcal{R}}$, $r_{j,h} \in \mathcal{R}$, $\lambda_{j,h} \in \Lambda_\sigma$, and $\delta'_j \in \Delta$), we set

$$\left( \sum_i \lambda_i \cdot \delta_i \right) \cdot \left( \sum_j r_j \cdot \delta'_j \right) := \sum_{i,j,h} \left( r_{j,h} \otimes (\lambda_i \lambda_{j,h}) \right) \cdot (\delta_i \delta'_j).$$

As above, extend $\tilde{\kappa} \in \tilde{\mathcal{X}}_{\text{arith}}$ to a continuous $\mathcal{O}$-algebra morphism $\tilde{\kappa}_N : \tilde{\mathcal{R}}_N \to \bar{\mathbb{Q}}_p$ by setting

$$\tilde{\kappa}_N \left( \sum_{i=1}^n x_i \cdot \delta_i \right) := \sum_{i=1}^n \kappa(x_i) \cdot \psi_\mathcal{R}(\delta_i)$$

for $x_i \in \tilde{\mathcal{R}}$ and $\delta_i \in \Delta$, where $\psi_\mathcal{R}$ is the character of $\mathcal{R}$. If we denote by $\tilde{\mathcal{X}}_N$ the $\mathcal{O}$-module of continuous $\mathcal{O}$-linear homomorphisms from $\tilde{\mathcal{R}}_N$ to $\bar{\mathbb{Q}}_p$, the above correspondence sets up an injective map $\tilde{\mathcal{X}}_{\text{arith}} \hookrightarrow \tilde{\mathcal{X}}_N$ and we let $\tilde{\mathcal{X}}_{N, \text{arith}}$ denote the image of $\tilde{\mathcal{X}}_{\text{arith}}$. We also have a map $\rho_N : \tilde{\mathcal{X}}_N \to \mathcal{X}_N$ induced from the map $\mathcal{R}_N \to \tilde{\mathcal{R}}_N$ taking $r \mapsto r \otimes 1$ by pull-back. The map $\rho_N$ also restricts to arithmetic points. The maps $\rho$ and $\rho_N$ make the following diagram commute:

$$\begin{array}{ccc}
\tilde{\mathcal{X}}_{\text{arith}} & \longrightarrow & \tilde{\mathcal{X}}_N \\
\rho \downarrow & & \downarrow \rho_N \\
\mathcal{X}_{\text{arith}} & \longrightarrow & \mathcal{X}_N
\end{array}$$

where the projections take a signature $(\epsilon, k)$ to $(\epsilon^2, 2k)$.

### 3.4. The $\Lambda$-adic Correspondence

In this part, we combine the explicit integral formula of Shimura and the fact that the toric integrals can be $p$-adically interpolated to show the existence of a $\Lambda$-adic Shimura-Shintani-Waldspurger correspondence with the expected interpolation property. This follows very closely [21, §6].

Let $\tilde{\kappa}_N \in \mathcal{X}_{\text{arith}}$ of signature $(\epsilon_\mathcal{E}, k_\mathcal{E})$. Let $L_r$ denote the order of $\mathbb{M}_2(F)$ consisting of matrices $\begin{pmatrix} a & b \frac{1}{Mp^e} \\ c & d \end{pmatrix}$ with $a, b, c, d \in \mathcal{O}_F$. Define

$$\mathcal{O}_{B,r} := \mathcal{O}_r^{-1} \left( \mathcal{O}_r (F(B \otimes 1) \cap L_r) \right)$$

Documenta Mathematica 18 (2013) 1–21
Then $O_{B,r}$ is the maximal order introduced in [2.1] (and denoted $O_B^r$ there) defined in terms of the maximal order $O_B$ and the integer $Mp'$. Also,

$$S := O_B \cap O_{B,r}$$

is an Eichler order of $B$ of level $Mp$ containing the fixed Eichler order $R$ of level $M$. With $\alpha \in V^* \cap O_{B,1}$, we have

$$i_F(\alpha) = \begin{pmatrix} a & b/(Mp) \\ c & -a \end{pmatrix}$$

in $M_2(F)$ with $a, b, c \in \mathcal{O}_F$ and we can consider the quadratic forms

$$Q_\alpha(x, y) := cx^2 - 2axy - (b/(Mp))y^2,$$

and

$$Q_\alpha(x, y) := Mp \cdot Q_\alpha(x, y) = Mpcx^2 - 2Mpaxy - by^2.$$  

Then $\tilde{Q}_\alpha(x, y)$ coefficients in $\mathcal{O}_F$ and, composing with $F \hookrightarrow \mathbb{R}$ and letting $x = z$, $y = 1$, we recover $Q_\alpha(z)$ and $\tilde{Q}_\alpha(z)$ of [2.1] (defined by means of the isomorphism $i_\infty$). Since each prime $\ell | Mp$ is split in $F$, the elements $a, b, c$ can be viewed as elements in $\mathbb{Z}_\ell$ via our fixed embedding $\bar{Q} \hookrightarrow \mathbb{Q}_\ell$, for any prime $\ell | Mp$ (we will continue writing $a, b, c$ for these elements, with a slight abuse of notation). So, letting $b_\alpha \in \mathbb{Z}$ such that $\tilde{i}_\ell(\alpha) \equiv (\ast b_\alpha/(Mp)) \mod \ell$, for all $\ell | Mp$, we have $b \equiv b_\alpha$ modulo $Mp\mathbb{Z}_\ell$ as elements in $\mathbb{Z}_\ell$, for all $\ell | Mp$, and thus we get

$$\eta_{\alpha}(\alpha) = \varepsilon_{\alpha}(b_\alpha) = \varepsilon_{\alpha}(b)$$

for $b$ as in [7].

For any $\nu \in \mathbb{D}$, we may define an $\mathcal{O}$-valued measure $j_\alpha(\nu)$ on $\mathbb{Z}_p^{\times}$ by the formula:

$$\int_{\mathbb{Z}_p^{\times}} f(t)j_\alpha(\nu)(t) := \int_{\mathbb{Z}_p^{\times} \times \mathbb{Z}_p^{\times}} f(\tilde{Q}_\alpha(x, y))d
\nu(x, y).$$

for any continuous function $f : \mathbb{Z}_p^{\times} \to \mathbb{C}$. Recall that the group of $\mathcal{O}$-valued measures on $\mathbb{Z}_p^{\times}$ is isomorphic to the Iwasawa algebra $\mathcal{O}[\mathbb{Z}_p^{\times}]$, and thus we may view $j_\alpha(\nu)$ as an element in $\mathcal{O}[\mathbb{Z}_p^{\times}]$ (see, for example, [1, §3.2]). In particular, for any group-like element $[\lambda] \in \mathcal{O}[\mathbb{Z}_p^{\times}]$ we have:

$$\int_{\mathbb{Z}_p^{\times}} f(t)d([\lambda] \cdot j_\alpha(\nu))(t) = \int_{\mathbb{Z}_p^{\times}} \left( \int_{\mathbb{Z}_p^{\times}} f(ts)d[\lambda](s) \right) j_\alpha(\nu)(t) = \int_{\mathbb{Z}_p^{\times}} f(\lambda t)d_j(\nu)(t).$$

On the other hand,

$$\int_{\mathbb{Z}_p^{\times} \times \mathbb{Z}_p^{\times}} f(Q_\alpha(x, y))d(\lambda \cdot \nu) = \int_{\mathbb{Z}_p^{\times} \times \mathbb{Z}_p^{\times}} f(Q_\alpha(\lambda x, \lambda y))d\nu = \int_{\mathbb{Z}_p^{\times} \times \mathbb{Z}_p^{\times}} f(\lambda^2 Q_\alpha(x, y))d\nu$$

and we conclude that $j_\alpha(\lambda \cdot \nu) = [\lambda^2] \cdot j_\alpha(\nu)$. In other words, $j_\alpha$ is a $\mathcal{O}[\mathbb{Z}_p^{\times}]$-linear map

$$j_\alpha : \mathbb{D} \to \mathcal{O}[\mathbb{Z}_p^{\times}].$$

Before going ahead, let us introduce some notation. Let $\chi$ be a Dirichlet character modulo $Mp'$, for a positive integer $r$, which we decompose accordingly
with the isomorphism \((\mathbb{Z}/Np\mathbb{Z})^\times \simeq (\mathbb{Z}/N\mathbb{Z})^\times \times (\mathbb{Z}/p\mathbb{Z})^\times\) into the product \(\chi = \chi_N \cdot \chi_p\) with \(\chi_N : (\mathbb{Z}/N\mathbb{Z})^\times \rightarrow \mathbb{C}^\times\) and \(\chi_p : (\mathbb{Z}/p\mathbb{Z})^\times \rightarrow \mathbb{C}^\times\). Thus, we will write \(\chi(x) = \chi_N(xN) \cdot \chi_p(x_p)\), where \(x_N\) and \(x_p\) are the projections of \(x \in (\mathbb{Z}/Np\mathbb{Z})^\times\) to \((\mathbb{Z}/N\mathbb{Z})^\times\) and \((\mathbb{Z}/p\mathbb{Z})^\times\), respectively. To simplify the notation, we will suppress the \(N\) and \(p\) from the notation for \(x_N\) and \(x_p\), thus simply writing \(x\) for any of the two. Using the isomorphism \((\mathbb{Z}/N\mathbb{Z})^\times \simeq (\mathbb{Z}/M\mathbb{Z})^\times \times (\mathbb{Z}/D\mathbb{Z})^\times\), decompose \(\chi_N\) as \(\chi_N = \chi_M \cdot \chi_D\) with \(\chi_M\) and \(\chi_D\) characters on \((\mathbb{Z}/M\mathbb{Z})^\times\) and \((\mathbb{Z}/D\mathbb{Z})^\times\), respectively. In the following, we only need the case when \(\chi_D = 1\).

Using the above notation, we may define a \(\mathcal{O}[\mathbb{Z}^\times_p]\)-linear map \(J_\alpha : \mathbb{D} \rightarrow \mathcal{O}[\mathbb{Z}^\times_p]\) by

\[
J_\alpha(\nu) = \epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot j_\alpha(\nu)
\]

with \(b\) as in \([6]\). Set \(\mathbb{D}_N := \mathbb{D} \otimes_{\mathcal{O}[\mathbb{Z}^\times_p]} \Lambda_N\), where the map \(\mathcal{O}[\mathbb{Z}^\times_p] \rightarrow \Lambda_N\) is induced from the map \(\mathbb{Z}^\times_p \rightarrow \mathbb{Z}^\times \times (\mathbb{Z}/N\mathbb{Z})^\times\) on group-like elements given by \(x \mapsto x \otimes 1\). Then \(J_\alpha\) can be extended to a \(\Lambda_N\)-linear map \(j_\alpha : \mathbb{D}_N \rightarrow \Lambda_N\). Setting \(\mathbb{R}_\mathbb{D} := \mathcal{R}_N \otimes_{\Lambda_N} \mathbb{D}_N\) and extending by \(\mathcal{R}_N\)-linearity over \(\Lambda_N\) we finally obtain a \(\mathcal{R}_N\)-linear map, again denoted by the same symbol,

\[
J_\alpha : \mathbb{D}_N \longrightarrow \mathbb{R}_\mathbb{D}.
\]

For \(\nu \in \mathbb{D}_N\) and \(r \in \mathcal{R}_N\) we thus have

\[
J_\alpha(r \otimes \nu) = \epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot r \otimes j_\alpha(\nu).
\]

For the next result, for any arithmetic point \(\kappa_N \in \mathcal{X}^\text{arith}_N\) coming from \(\kappa \in \mathcal{X}^\text{arith}\), extend \(\rho_\kappa\) in \([5]\) by \(\mathcal{R}_N\)-linearity over \(\mathcal{O}[\mathbb{Z}^\times_p]\), to get a map

\[
\rho_\kappa : \mathbb{D}_N \longrightarrow V_{\eta_N}
\]

defined by \(\rho_\kappa(\nu \otimes r) := \rho_\kappa(\nu) \cdot \kappa_N(r)\), for \(\nu \in \mathbb{D}\) and \(r \in \mathcal{R}_N\). To simplify the notation, set

\[
(\nu, \alpha)_{\kappa_N} := \rho_\kappa(\nu)(\bar{Q}_\alpha^{n_N}/2).
\]

The following is essentially \([21]\) Lemma (6.1)].

**Lemma 3.2.** Let \(\bar{\kappa}_N \in \mathcal{X}^\text{arith}_N\) with signature \((\epsilon_{\bar{\kappa},k_\alpha})\) and define \(\kappa_N := p_N(\bar{\kappa}_N)\). Then for any \(\nu \in \mathbb{D}_\mathcal{R}_N\) we have:

\[
\bar{\kappa}_N(J_\alpha(\nu)) = \eta_{\epsilon_\alpha}(\alpha) \cdot (\nu, \alpha)_{\kappa_N}.
\]

**Proof.** For \(\nu \in \mathbb{D}_N\) and \(r \in \mathcal{R}_N\) we have

\[
\bar{\kappa}_N(J_\alpha(r \otimes \nu)) = \bar{\kappa}_N(\epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot r \otimes j_\alpha(\nu))
\]

\[
= \epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot \bar{\kappa}_N(r \otimes 1) \cdot \bar{\kappa}_N(1 \otimes j_\alpha(\nu))
\]

\[
= \epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot \kappa_N(r) \cdot \int_{\mathbb{Z}_p^\times} \bar{\kappa}_N(t)d\rho_\alpha(\nu)
\]

and thus, noticing that \(\bar{\kappa}_N\) restricted to \(\mathbb{Z}_p^\times\) is \(\bar{\kappa}_N(t) = \epsilon_{\bar{\nu},p}(t)t^{n_N}\), we have

\[
\bar{\kappa}_N(J_\alpha(r \otimes \nu)) = \epsilon_{\bar{\nu},M}(b) \cdot \epsilon_{\bar{\nu},p}(-1) \cdot \kappa_N(r) \int_{\mathbb{Z}_p^\times \mathbb{Z}_p^\times} \epsilon_{\bar{\nu},p}(Q_\alpha(x, y))Q_\alpha(x, y)^{n_N}/2d\nu.
\]
Recalling \([8]\), and viewing \(a, b, c\) as elements in \(\mathbb{Z}_p\), we have, for \((x, y) \in \mathbb{Z}_p \times \mathbb{Z}_p^\times\),

\[
\varepsilon_{a, b}(\tilde{Q}_a(x, y)) = \varepsilon_{a, b}(-by^2) = \varepsilon_{a, b}(-b)e_{a, b}(y^2) = \varepsilon_{a, b}(-b)e_{a, b}(y).
\]

Thus, since \(\varepsilon_{\kappa}(-1)^2 = 1\), we get:

\[
\tilde{\kappa}_N(J_\nu(r \otimes \nu)) = \kappa_N(r) \cdot \varepsilon_{\kappa, M}(b) \cdot \varepsilon_{\kappa, p}(b) \cdot \rho_\nu(\nu)(\tilde{Q}_{\kappa, N}^{x, y}/2) = \eta_\kappa(\alpha) \cdot \langle \nu, \alpha \rangle_{\kappa, N}
\]

where for the last equality use \([9]\) and \([10]\). □

Define

\[
\mathbb{W}_{R_N} := \mathbb{W} \otimes_{\mathcal{O}[\mathbb{Z}_p^\times]} \mathcal{R}_N,
\]

the structure of \(\mathcal{O}[\mathbb{Z}_p^\times]\)-module of \(\mathcal{R}_N\) being that induced by the composition of the two maps \(\mathcal{O}[\mathbb{Z}_p^\times] \rightarrow \Lambda_N \rightarrow \mathcal{R}_N\) described above. There is a canonical map

\[
\vartheta : \mathbb{W}_{R_N} \rightarrow H^1(\Gamma_0, \mathcal{D}_{R_N})
\]

described as follows: if \(\nu_\gamma\) is a representative of an element \(\nu \in \mathbb{W}\) and \(r \in \mathcal{R}_N\), then \(\vartheta(\nu \otimes r)\) is represented by the cocycle \(\nu_\gamma \otimes r\).

For \(\nu \in \mathbb{W}_{R_N}\) represented by \(\nu_\gamma\) and \(\xi \geq 1\) an integer, define

\[
\theta_{\xi}(\nu) := \sum_{\gamma \in \Gamma_1 \backslash \Gamma, \varrho(\gamma) = \xi} J_{\nu_\gamma}(\nu_{\gamma_{\nu_\gamma}}) / t_{\nu_\gamma}.
\]

**Definition 3.3.** For \(\nu \in \mathbb{W}_{R_N}\), the formal Fourier expansion

\[
\Theta(\nu) := \sum_{\xi \geq 1} \theta_{\xi}(\nu) q^\xi
\]

in \(\mathcal{R}_N[q]\) is called the \(\Lambda\)-adic Shimura-Shintani-Waldspurger lift of \(\nu\). For any \(\tilde{\kappa} \in \tilde{X}_{\text{arith}}\), the formal power series expansion

\[
\Theta(\nu)(\tilde{\kappa}_N) := \sum_{\xi \geq 1} \tilde{\kappa}_N(\theta_{\xi}(\nu)) q^\xi
\]

is called the \(\tilde{\kappa}\)-specialization of \(\Theta(\nu)\).

There is a natural map

\[
\mathbb{W}_R \rightarrow \mathbb{W}_{R_N}
\]

taking \(\nu \otimes r\) to itself (use that \(\mathcal{R}\) has a canonical map to \(\mathcal{R}_N \simeq \mathcal{R}[\Delta]\), as described above). So, for any choice of sign, \(\Phi^\pm \in \mathbb{W}_R\) will be viewed as an element in \(\mathbb{W}_{R_N}\).

From now on we will use the following notation. Fix \(\tilde{\kappa}_0 \in \tilde{X}_{\text{arith}}\) and put \(\kappa_0 := p(\tilde{\kappa}_0) \in X_{\text{arith}}\). Recall the neighborhood \(U_0\) of \(\kappa_0\) in Theorem \([5, 1]\). Define \(U_{0}^\text{arith} := p^{-1}(U_0)\) and

\[
\tilde{U}_{0}^\text{arith} := \tilde{U}_0 \cap \tilde{X}_{\text{arith}}.
\]

For each \(\tilde{\kappa} \in \tilde{U}_{0}^\text{arith}\) put \(\kappa := p(\tilde{\kappa}) \in U_{0}^\text{arith}\). Recall that if \((\varepsilon_{\kappa, k_\kappa})\) is the signature of \(\tilde{\kappa}\), then \((\varepsilon_{\kappa, k_\kappa}) := (\varepsilon_{\kappa}^2, 2k_\kappa)\) is that of \(\kappa_0\). For any \(\kappa := p(\tilde{\kappa})\) as above, we may consider the modular form

\[
f_{\kappa}^{JL} \in \mathcal{S}_{\kappa, \gamma}(\Gamma_{\kappa}, \varepsilon_{\kappa})
\]
and its Shimura-Shintani-Waldspurger lift
\[ h_{\kappa} = \sum_{\xi} a_{\xi}(h_{\kappa})q^{\xi} \in S_{\kappa+1/2}(4Np^{\kappa}, \chi_{\kappa}), \quad \text{where } \chi_{\kappa}(x) := \epsilon_{\kappa}(x) \left( -\frac{1}{x} \right)^{\kappa}, \]
normalized as in \( \mathfrak{2} \) and \( \mathfrak{3} \). For our fixed \( \kappa_{0} \), recall the elements \( \Phi := \Phi^{+} \) chosen as in Theorem \( \mathfrak{5} \) and define \( \phi_{\kappa} := \phi_{\kappa}^{+} \) and \( \Omega_{\kappa} := \Omega_{\kappa}^{+} \) for \( \kappa \in \mathcal{U}_{0}^{\text{arith}} \).

**Proposition 3.4.** For all \( \bar{\kappa} \in \mathcal{U}_{0}^{\text{arith}} \) such that \( r_{\kappa} = 1 \) we have
\[ \tilde{\kappa}_{N}(\theta_{\kappa}(\Phi)) = \Omega_{\kappa} \cdot a_{\kappa}(h_{\kappa}) \quad \text{and} \quad \Theta(\Phi)(\tilde{\kappa}_{N}) = \Omega_{\kappa} \cdot h_{\kappa}. \]

**Proof.** By Lemma \( \mathfrak{3.2} \) we have
\[ \tilde{\kappa}_{N}(\theta_{\kappa}(\Phi)) = \sum_{C \in R(\Gamma_{1}, q(C)) = \xi} \eta_{\kappa}(\alpha_{C}) \frac{\eta_{\kappa}(\alpha_{C})}{t_{\alpha_{C}}} \rho_{\kappa,N}(\Phi)(\tilde{Q}_{\alpha_{C}}^{N/2}). \]
Using Theorem \( \mathfrak{3.4} \) we get
\[ \tilde{\kappa}_{N}(\theta_{\kappa}(\Phi)) = \sum_{C \in R(\Gamma_{1}, q(C)) = \xi} \eta_{\kappa}(\alpha_{C}) \frac{\eta_{\kappa}(\alpha_{C})}{t_{\alpha_{C}}} \phi_{\kappa}(\tilde{Q}_{\alpha_{C}}^{N/2}). \]
Now \( \mathfrak{2} \) shows the statement on \( \tilde{\kappa}_{N}(\theta_{2}(\Phi)) \), while that on \( \Theta(\Phi)(\tilde{\kappa}_{N}) \) is a formal consequence of the previous one. \( \square \)

**Corollary 3.5.** Let \( a_{p} \) denote the image of the Hecke operator \( T_{p} \) in \( \mathcal{R} \). Then \( \Theta(\Phi)|T_{p}^{2} = a_{p} \cdot \Theta(\Phi) \).

**Proof.** For any \( \kappa \in \mathcal{X}^{\text{arith}} \), let \( a_{p}(\kappa) := \kappa(T_{p}) \), which is a \( p \)-adic unit by the ordinarity assumption. For all \( \bar{\kappa} \in \mathcal{U}_{0}^{\text{arith}} \) with \( r_{\kappa} = 1 \), we have
\[ \Theta(\Phi)(\tilde{\kappa}_{N}|T_{p}^{2} = \Omega_{\kappa} \cdot h_{\kappa}|T_{p}^{2} = a_{p}(\kappa) \cdot \Omega_{\kappa} \cdot h_{\kappa} = a_{p}(\kappa) \cdot \Theta(\Phi)(\tilde{\kappa}_{N}). \]
Consequently,
\[ \tilde{\kappa}_{N}(\theta_{\ell^{2}}(\Phi)) = a_{p}(\kappa) \cdot \tilde{\kappa}_{N}(\theta_{2}(\Phi)) \]
for all \( \bar{\kappa} \) such that \( r_{\kappa} = 1 \). Since this subset is dense in \( \tilde{\mathcal{K}}_{N} \), we conclude that \( \theta_{\ell^{2}}(\Phi) = a_{p} \cdot \theta_{2}(\Phi) \) and so \( \Theta(\Phi)|T_{p}^{2} = a_{p} \cdot \Theta(\Phi) \). \( \square \)

For any integer \( n \geq 1 \) and any quadratic form \( Q \) with coefficients in \( F \), write \( \lfloor Q \rfloor_{n} \) for the class of \( Q \) modulo the action of \( \iota_{F}(\Gamma_{n}) \). Define \( \mathcal{F}_{n,\xi} \) to be the subset of the \( F \)-vector space of quadratic forms with coefficients in \( F \) consisting of quadratic forms \( Q_{\alpha} \) such that \( \alpha \in V^{*} \cap \mathcal{O}_{B,n} \) and \( -\nu(\alpha) = \xi \). Writing \( \delta_{Q_{\alpha}} \) for the discriminant of \( Q_{\alpha} \), the above set can be equivalently described as
\[ \mathcal{F}_{n,\xi} := \{ Q_{\alpha} | \alpha \in V^{*} \cap \mathcal{O}_{B,n}, \delta_{Q_{\alpha}} = Np^{\nu} \xi \}. \]
Define \( \mathcal{F}_{n,\xi}/\Gamma_{n} \) to be the set \( \{ [Q_{\alpha}]_{n} | Q_{\alpha} \in \mathcal{F}_{n,\xi} \} \) of equivalence classes of \( \mathcal{F}_{n,\xi} \) under the action of \( \iota_{F}(\Gamma_{n}) \). A simple computation shows that \( Q_{\alpha} - \gamma_{\alpha}g = Q_{\alpha} \) for all \( \alpha \in V^{*} \) and all \( g \in \Gamma_{n} \), and thus we find
\[ \mathcal{F}_{n,\xi}/\Gamma_{n} = \{ [Q_{\alpha}]_{n} | C \in R(\Gamma_{n}), \delta_{Q_{\alpha}} = Np^{\nu} \xi \}. \]
We also note that, in the notation of [21], if $f$ has weight character $\psi$, defined modulo $Np^m$, and level $\Gamma_n$, the Fourier coefficients $a_\xi(h)$ of the Shimura-Shintani-Waldspurger lift $h$ of $f$ are given by
\begin{equation}
 a_\xi(h) = \sum_{[Q] \in \mathcal{F}_m/\Gamma_n} \frac{\psi(Q)}{t_Q} \phi^+_Q(Q(z)^{k-1})
\end{equation}
and, if $Q = \bar{Q}_\alpha$, we put $\psi(Q) := \eta_\alpha(b_\alpha)$ and $t_Q := t_\alpha$. Also, if we let
\[ \mathcal{F}_n/\Gamma_n := \prod_\xi \mathcal{F}_{n,\xi}/\Gamma_n \]
we can write
\begin{equation}
 h = \sum_{[Q] \in \mathcal{F}_m/\Gamma_n} \frac{\psi(Q)}{t_Q} \phi^+_Q(Q(z)^{k-1})q^{\delta_Q/(Np^m)}.
\end{equation}
Fix now an integer $m \geq 1$ and let $n \in \{1, m\}$. For any $t \in (\mathbb{Z}/p^n\mathbb{Z})^\times$ and any integer $\xi \geq 1$, define $\mathcal{F}_{n,\xi,t}$ to be the subset of $\mathcal{F}_{n,\xi}$ consisting of forms such that $Np^m b_\alpha \equiv t \mod Np^m$. Also, define $\mathcal{F}_{n,\xi,t}/\Gamma_n$ to be the set of equivalence classes of $\mathcal{F}_{n,\xi,t}$ under the action of $i_F(\Gamma_n)$. If $\alpha \in V^* \cap O_{B,m}$ and
\[ i_F(\alpha) = \begin{pmatrix} a & b \\ c & -a \end{pmatrix}, \]
then
\begin{equation}
 \bar{Q}_\alpha(\bar{x}, \bar{y}) = Np^m c x^2 - 2Np^m a xy - Np^m b y^2
\end{equation}
from which we see that there is an inclusion $\mathcal{F}_{m,\xi,t} \subseteq \mathcal{F}_{1,\xi,0^{-1},t}$. If $\bar{Q}_\alpha$ and $\bar{Q}_{\alpha'}$ belong to $\mathcal{F}_{m,\xi,t}$, and $\alpha' = gag^{-1}$ for some $g \in \Gamma_m$, then, since $\Gamma_m \subseteq \Gamma_1$, we see that $\bar{Q}_\alpha$ and $\bar{Q}_{\alpha'}$ represent the same class in $\mathcal{F}_{1,\xi,0^{-1},t}/\Gamma_1$. This shows that $[\bar{Q}_\alpha]_{m} \mapsto [\bar{Q}_{\alpha}]_{1}$ gives a well-defined map
\[ \pi_{m,\xi,t} : \mathcal{F}_{m,\xi,t}/\Gamma_m \rightarrow \mathcal{F}_{1,\xi,0^{-1},t}/\Gamma_1. \]

**Lemma 3.6.** The map $\pi_{m,\xi,t}$ is bijective.

**Proof.** We first show the injectivity. For this, suppose $\bar{Q}_\alpha$ and $\bar{Q}_{\alpha'}$ are in $\mathcal{F}_{m,\xi,t}$ and $[\bar{Q}_\alpha]_{m} = [\bar{Q}_{\alpha'}]_{1}$. So there exists $g = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$ in $i_F(\Gamma_1)$ such that such that $\bar{Q}_\alpha = \bar{Q}_{\alpha'}|g$. If $\bar{Q}_\alpha = cx^2 - 2axy - by^2$, and easy computation shows that $\bar{Q}_{\alpha'} = c'x^2 - 2a'xy - b'y^2$ with
\[ c' = ca^2 - 2ac\gamma - b\gamma^2 \]
\[ a' = -ca\beta + a\beta\gamma + a\alpha\delta + b\gamma\delta \]
\[ b' = -c\beta^2 + 2a\beta\delta + b\delta^2. \]
The first condition shows that $\gamma \equiv 0 \mod Np^m$. We have $b \equiv b' \equiv t \mod Np^m$, so $\delta^2 \equiv 1 \mod Np^m$. Since $\delta \equiv 1 \mod Np$, we see that $\delta \equiv 1 \mod Np^m$ too.
We now show the surjectivity. For this, fix \([\tilde{Q}_{\kappa_c}]_1\) in the target of \(\pi\), and choose a representative 

\[
\tilde{Q}_{\kappa_c} = cx^2 - 2axy - by^2
\]

(recall \(Mp^m\xi|\delta_{\tilde{Q}_{\kappa_c}}, Np[c, Np[a, and \(b \in \mathcal{O}_p^*\), the last condition due to \(\eta_\psi(\alpha_c) \neq 0\)). By the Strong Approximation Theorem, we can find \(\tilde{g} \in \Gamma_1\) such that

\[
i\ell(\tilde{g}) \equiv \begin{pmatrix} 1 & 0 \\ ab^{-1} & 1 \end{pmatrix} \text{ mod } Np^m
\]

for all \(\ell|Np\). Take \(g := i\ell(\tilde{g})\), and put \(\alpha := g^{-1}\alpha_cg\). An easy computation, using the expressions for \(a', b', c'\) in terms of \(a, b, c\) and \(g = \left( \begin{array}{cc} a' & b' \\ c' & d' \end{array} \right)\) as above, shows that \(\alpha \in V^* \cap \mathcal{O}_{B, m}, \eta_\psi(\alpha) = t\) and \(\delta_{\tilde{Q}_{\kappa}} = Np^m\xi\), and it follows that \(\tilde{Q}_\alpha \in \mathcal{F}_{m,t}\). Now

\[
\pi([\tilde{Q}_{\kappa_c}]_1) = [\tilde{Q}_\alpha]_1 = [\tilde{Q}_{\kappa} - t\alpha_c\bar{g}]_1 = [\tilde{Q}_{\kappa_c}]_1
\]

where the last equality follows because \(g \in \Gamma_1\).

**Proposition 3.7.** For all \(\tilde{k} \in \tilde{\mathcal{L}}^\text{arith}\) we have

\[
\Theta(\Phi)(\tilde{k}_{\kappa})|T_p^{r_\kappa - 1} = \Omega_{\kappa} \cdot h_{\kappa}.
\]

**Proof.** For \(r_\kappa = 1\), this is Proposition 3.4 above, so we may assume \(r_\kappa > 1\). As in the proof of Proposition 3.4, combining Lemma 3.2 and Theorem 3.1 we get

\[
\Theta(\Phi)(\tilde{k}_{\kappa}) = \sum_{\xi \geq 1} \left( \sum_{\ell \in R(1), \ell(\xi) = \xi} \frac{\eta_{\kappa}(\alpha_{\kappa}) \cdot \Omega_{\kappa}}{t_{\kappa}} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) \right) q^\xi
\]

which, by Lemma 3.3 and 3.4 above we may rewrite as

\[
\Theta(\Phi)(\tilde{k}_{\kappa}) = \sum_{[Q] \in \mathcal{F}_1/\Gamma_1} \frac{\epsilon_{\kappa}(Q) \cdot \Omega_{\kappa}}{t_Q} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) q^{\delta_Q/(Np)}
\]

By definition of the action of \(T_p\) on power series, we have

\[
\Theta(\Phi)(\tilde{k}_{\kappa})|T_p^{r_\kappa - 1} = \sum_{[Q] \in \mathcal{F}_1/\Gamma_1} \frac{\epsilon_{\kappa}(Q) \cdot \Omega_{\kappa}}{t_Q} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) q^{\delta_Q/(Np^{r_\kappa})}.
\]

Setting \(\mathcal{F}_{n,t}/\Gamma_n := \prod_{\ell \geq 1} \mathcal{F}_{n, t, \ell}/\Gamma_n\) for \(n \in \{1, r_\kappa\}\), Lemma 3.6 shows that \(\mathcal{F}_{1, t}^* := \{[Q] \in \mathcal{F}_{1,t}/\Gamma_1, t\} such \ text{ that } p^r|\delta_Q\ is equal to \mathcal{F}_{r_\kappa, t}^*\). Therefore, splitting the above sum over \(t \in (\mathbb{Z}/Np^{r_\kappa}\mathbb{Z})^\times\), we get

\[
\Theta(\Phi)(\tilde{k}_{\kappa})|T_p^{r_\kappa - 1} = \sum_{t \in (\mathbb{Z}/p^{r_\kappa-1}\mathbb{Z})} \sum_{[Q] \in \mathcal{F}_{1,t}} \frac{\epsilon_{\kappa}(Q) \cdot \Omega_{\kappa}}{t_Q} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) q^{\delta_Q/(Np^{r_\kappa})}
\]

\[
= \sum_{t \in (\mathbb{Z}/p^{r_\kappa-1}\mathbb{Z})} \sum_{[Q] \in \mathcal{F}_{m,t}/\Gamma_m} \frac{\epsilon_{\kappa}(Q) \cdot \Omega_{\kappa}}{t_Q} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) q^{\delta_Q/(Np^{r_\kappa})}
\]

\[
= \sum_{[Q] \in \mathcal{F}_{m,t}/\Gamma_m} \frac{\epsilon_{\kappa}(Q) \cdot \Omega_{\kappa}}{t_Q} \phi_{\kappa}(Q_{\kappa_c}^{1-1}) q^{\delta_Q/(Np^{r_\kappa})}.
\]
Comparing this expression with \[\{12\}\] gives the result. □

We are now ready to state the analogue of \[\{21\}\] Thm. 3.3], which is our main result. For the reader’s convenience, we briefly recall the notation appearing below. We denote by $\mathcal{X}$ the points of the ordinary Hida Hecke algebra, and by $\mathcal{X}^{\text{arith}}$ its arithmetic points. For $\kappa_0 \in \mathcal{X}^{\text{arith}}$, we denote by $U_0$ the $p$-adic neighborhood of $\kappa_0$ appearing in the statement of Theorem 3.1 and put $U_0^{\text{arith}} := U_0 \cap \mathcal{X}^{\text{arith}}$. We also denote by $\Phi := \Phi^+ \in W_\text{ord}$ the cohomology class appearing in Theorem 3.1. The points $\tilde{\mathcal{X}}$ of the metaplectic Hida Hecke algebra defined in \[\{3.3\}\] are equipped with a canonical map $p : \mathcal{X}^{\text{arith}} \to \mathcal{X}^{\text{arith}}$ on arithmetic points. Let $\tilde{U}_0^{\text{arith}} := \tilde{U}_0 \cap \tilde{\mathcal{X}}^{\text{arith}}$. For each $\tilde{\kappa} \in \tilde{U}_0^{\text{arith}}$, put $\kappa = p(\tilde{\kappa}) \in U_0^{\text{arith}}$. Recall that if $(\epsilon_{\tilde{\kappa}}, k_{\tilde{\kappa}})$ is the signature of $\tilde{\kappa}$, then the signature of $\kappa$ is $(\epsilon_{\kappa}, k_{\kappa}) := (\epsilon_{\tilde{\kappa}}^2, 2k_{\tilde{\kappa}})$. For any $\kappa := p(\tilde{\kappa})$ as above, we may consider the modular form

$$f_{\kappa}^{\text{JL}} \in S_{\kappa}(\Gamma_{\kappa}, \epsilon_{\kappa})$$

and its Shimura-Shintani-Waldspurger lift

$$h_{\kappa} = \sum_{\xi} a_{\xi}(h_{\kappa}) q^\xi \in S_{\kappa + 1/2}(4Np^{r_{\kappa}}; \chi_{\kappa}),$$

where $\chi_{\kappa}(x) := \epsilon_{\kappa}(x) \left(\frac{-1}{x}\right)^{k_{\kappa}}$, normalized as in \[\{2\}\] and \[\{3\}\]. Finally, for $\tilde{\kappa} \in \tilde{\mathcal{X}}^{\text{arith}}$, we denote by $\tilde{\kappa}_N$ its extension to the metaplectic Hecke algebra $\tilde{\mathcal{R}}_N$ defined in \[\{3.3\}\].

**Theorem 3.8.** Let $\kappa_0 \in \mathcal{X}^{\text{arith}}$. Then there exists a choice of $p$-adic periods $\Omega_{\kappa}$ for $\kappa \in U_0$ such that the $\Lambda$-adic Shimura-Shintani-Waldspurger lift of $\Phi$

$$\Theta(\Phi) := \sum_{\xi \geq 1} \theta_{\xi}(\Phi) q^\xi$$

in $\mathcal{R}_N[q]$ has the following properties:

1. $\Omega_{\kappa_0} \neq 0$.
2. For any $\tilde{\kappa} \in \tilde{U}_0^{\text{arith}}$, the $\kappa$-specialization of $\Theta(\Phi)$

$$\Theta(\nu)(\tilde{\kappa}_N) := \sum_{\xi \geq 1} \tilde{\kappa}(\theta_{\xi}(\Phi)) q^\xi \text{ belongs to } S_{\kappa + 1/2}(4Np^{r_{\kappa}}; \chi_{\kappa}'),$$

where $\chi_{\kappa}'(x) := \chi_{\kappa}(x) \cdot (\chi_{\kappa}(x))^{k_{\kappa}}$, and satisfies

$$\Theta(\Phi)(\tilde{\kappa}_N) = \Omega_{\kappa} \cdot h_{\kappa}|T_p^{1-r_{\kappa}}.$$ 

**Proof.** The elements $\Omega_{\kappa}$ are those $\Omega_\kappa^+$ appearing in Theorem 3.1 which we used in Propositions 3.3 and 3.7 above, so (1) is clear. Applying $T_p^{r_{\kappa}-1}$ to the formula of Proposition 3.7 using Corollary 3.5 and applying $a_p(\kappa)^{1-r_{\kappa}}$ on both sides gives

$$\Theta(\Phi)(\tilde{\kappa}_N) = a_p(\kappa)^{1-r_{\kappa}} \cdot \Omega_{\kappa} \cdot h_{\kappa}|T_p^{r_{\kappa}-1}.$$ 

By \[\{18\}\] Prop. 1.9], each application of $T_p$ has the effect of multiplying the character by $(\chi_{\kappa}(x))^{k_{\kappa}}$, hence

$$h_{\kappa}' := h_{\kappa}|T_p^{r_{\kappa}-1} \in S_{\kappa + 1/2}(4Np^{r_{\kappa}}; \chi_{\kappa}').$$

Documenta Mathematica 18 (2013) 1–21
with \( \chi'_k \) as in the statement. This gives the first part of (2), while the last formula follows immediately from Proposition \ref{prop:2}. \qed

Remark 3.9. Theorem \ref{thm:1} is a direct consequence of Theorem \ref{thm:3.8}, as we briefly show below.

Recall the embedding \( \mathbb{Z}^{\geq 2} \hookrightarrow \text{Hom}(\mathbb{Z}_p^\times, \mathbb{Z}_p^\times) \) which sends \( k \in \mathbb{Z}^{\geq 2} \) to the character \( x \mapsto x^{k-2} \). Extending characters by \( \mathcal{O} \)-linearity gives a map

\[
\mathbb{Z}^{\geq 2} \rightarrow \mathcal{X}(\Lambda) := \text{Hom}_{\text{cont}}(\Lambda, \mathbb{Q}_p).
\]

We denote by \( k^{(\Lambda)} \) the image of \( k \in \mathbb{Z}^{\geq 2} \) in \( \mathcal{X}(\Lambda) \) via this embedding. We also denote by \( \varpi : \mathcal{X} \rightarrow \mathcal{X}(\Lambda) \) the finite-to-one map obtained by restriction of homomorphisms to \( \Lambda \). Let \( k^{(\mathcal{R})} \) be a point in \( \mathcal{X} \) of signature \( (k, 1) \) such that \( \varpi(k^{(\mathcal{R})}) = k^{(\Lambda)} \). A well-known result by Hida (see [6] Cor. 1.4]) shows that \( \mathcal{R}/\Lambda \) is unramified at \( k^{(\Lambda)} \). As shown in [21] §1, this implies that there is a section \( s_{k^{(\Lambda)}}(\varpi) \) which is defined on a neighborhood \( \mathcal{U}_{k^{(\Lambda)}} \) of \( k^{(\Lambda)} \) in \( \mathcal{X}(\Lambda) \) and sends \( k^{(\Lambda)} \) to \( k^{(\mathcal{R})} \).

Fix now \( k_0 \) as in the statement of Theorem \ref{thm:1} corresponding to a cuspidal \( f_0 \) of weight \( k_0 \) with trivial character. The form \( f_0 \) corresponds to an arithmetic character \( k_0^{(\mathcal{R})} \) of signature \( (1, k_0) \) belonging to \( \mathcal{X} \). Let \( \mathcal{U}_0 \) be the inverse image of \( \mathcal{U}_0 \) under the section \( s_{k_0}^{-1} \) of \( \mathcal{X} \), where \( \mathcal{U}_0 \subseteq \mathcal{X} \) is the neighborhood of \( k_0^{(\mathcal{R})} \) in Theorem \ref{thm:3.8}. Extending scalars by \( \mathcal{O} \) gives, as above, an injective continuous map \( \text{Hom}(\mathbb{Z}_p^\times, \mathbb{Z}_p^\times) \hookrightarrow \mathcal{X}(\Lambda) \), and we let \( \mathcal{U}_0' \) be any neighborhood of the character \( x \mapsto x^{k_0-2} \) which maps to \( \mathcal{U}_0 \) and is contained in the residue class of \( k_0 \) modulo \( p-1 \). Composing this map with the section \( \mathcal{U}_0 \hookrightarrow \mathcal{U}_0' \) gives a continuous injective map

\[
\varsigma : \mathcal{U}_0 \hookrightarrow \mathcal{U}_0' \hookrightarrow \mathcal{U}_0
\]

which takes \( k_0 \) to \( k_0^{(\mathcal{R})} \), since by construction the image of \( k_0 \) by the first map is \( k_0^{(\Lambda)} \). We also note that, more generally, \( \varsigma(k) = k^{(\mathcal{R})} \) because by construction \( \varsigma(k) \) restricts to \( k^{(\Lambda)} \) and its signature is \( (1, k) \), since the character of \( \varsigma(k) \) is trivial. To show the last assertion, recall that the character of \( \varsigma(k) \) is \( \psi_k \cdot \psi_\mathcal{R} \cdot \omega^{-k} \), and note that \( \psi_k \) is trivial because \( k^{(\Lambda)}(x) = x^{k_0-1} \), and \( \psi_\mathcal{R} \cdot \omega^{-k} \) is trivial because the same is true for \( k_0 \) and \( k \equiv k_0 \) modulo \( p-1 \). In other words, arithmetic points in \( \varsigma(\mathcal{U}_0) \) correspond to cusps with trivial character. This is the Hida family of forms with trivial character that we considered in the Introduction.

We can now prove Theorem \ref{thm:1}. For all \( k \in \mathcal{U}_0 \cap \mathbb{Z}^{\geq 2} \), put \( \Omega_k := \Omega_{k^{(\mathcal{R})}} \) and define \( \Theta := \Theta(\Phi) \circ \varsigma \) with \( \Phi \) as in Theorem \ref{thm:3.8} for \( \kappa_0 = k_0^{(\mathcal{R})} \). Applying Theorem \ref{thm:3.8} to \( k_0^{(\mathcal{R})} \), and restricting to \( \varsigma(\mathcal{U}_0) \), shows that \( U_0, \Omega_k \) and \( \Theta \) satisfy the conclusion of Theorem \ref{thm:1}.

Remark 3.10. For \( \kappa \in \mathcal{U}_0^{\text{cont}} \) of signature \( (\epsilon_\kappa, k_\kappa) \) with \( r_\kappa = 1 \) as in the above theorem, \( h_{\kappa} \) is trivial if \( (-1)^{k_\kappa} \neq \epsilon_\kappa(-1) \). However, since \( \phi_{\kappa_0} \neq 0 \), it follows that \( h_{\kappa_0} \) is not trivial as long as the necessary condition \( (-1)^{k_0} = \epsilon_0(-1) \) is verified.
Remark 3.11. This result can be used to produce a quaternionic \( \Lambda \)-adic version of the Saito-Kurokawa lifting, following closely the arguments in \cite{LongoNicole12}.

ON A POSITIVE EQUICHARACTERISTIC
VARIANT OF THE $p$-CURVATURE CONJECTURE

HÉLÈNE ESNault, ADRIAN LANGER

Received: October 26, 2012
Communicated by Takeshi Saito

Abstract. Our aim is to formulate and prove a weak form in equal characteristic $p > 0$ of the $p$-curvature conjecture. We also show the existence of a counterexample to a strong form of it.

2010 Mathematics Subject Classification: 14D05, 14E20, 14F35, 11G10, 11G99
Keywords and Phrases: varieties in positive characteristic, stratified bundles, étale trivializable bundles, monodromy group, abelian varieties

Introduction

If $(E, \nabla)$ is a vector bundle with an algebraic integrable connection over a smooth complex variety $X$, then it is defined over a smooth scheme $S$ over $\text{Spec} \mathbb{Z}[\frac{1}{N}]$ for some positive integer $N$, so $(E, \nabla) = (E_S, \nabla_S) \otimes_S \mathbb{C}$ over $X = X_S \otimes_S \mathbb{C}$ for a geometric generic point $\mathbb{Q}(S) \subset \mathbb{C}$. Grothendieck-Katz’s $p$-curvature conjecture predicts that if for all closed points $s$ of some non-trivial open $U \subset S$, the $p$-curvature of $(E_S, \nabla_S) \times_S s$ is zero, then $(E, \nabla)$ is trivialized by a finite étale cover of $X$ (see e.g. [An, Conj.3.3.3]). Little is known about it. N. Katz proved it for Gauss-Manin connections [Ka], for $S$ finite over $\text{Spec} \mathbb{Z}[\frac{1}{M}]$ (i.e., if $X$ can be defined over a number field), D. V. Chudnovsky and G. V. Chudnovsky in [CC] proved it in the rank 1 case and Y. André in [An] proved it in case the Galois differential Lie algebra of $(E, \nabla)$ at the generic point of $S$ is solvable (and for extensions of connections satisfying the conjecture). More recently, B. Farb and M. Kisin [FK] proved it for certain locally symmetric varieties $X$. In general, one is lacking methods to think of the problem.

The first author is supported by the SFB/TR45 and the ERC Advanced Grant 226257. The second author is supported by the Bessel Award of the Humboldt Foundation and a Polish MNiSW grant (contract number N N201 420639).
Y. André in [An II] and E. Hrushovskiy in [Hr V] formulated the following equal characteristic 0 analog of the conjecture: if $X \to S$ is a smooth morphism of smooth connected varieties defined over a characteristic 0 field $k$, then if $(E_S, \nabla_S)$ is a relative integrable connection such that for all closed points $s$ of some non-trivial open $U \subset S$, $(E_S, \nabla_S) \times_S s$ is trivialized by a finite étale cover of $X \times_S s$, then $(E, \nabla)|_{X_{\eta}}$ should be trivialized by a finite étale cover of $X_{\eta}$, where $\eta$ is a geometric generic point and $X_{\eta} = X \times_S \eta$. So the characteristic 0 analogy to integrable connections is simply integrable connections, and to the $p$-curvature condition is the trivialization of the connection by a finite étale cover. André proved it [An Prop. 7.1.1], using Jordan’s theorem and Simpson’s moduli of flat connections, while Hrushovsky [Hr p.116] suggested a proof using model theory.

It is tempting to formulate an equal characteristic $p > 0$ analog of Y. André’s theorem. A main feature of integrable connections over a field $k$ of characteristic 0 is that they form an abelian, rigid, $k$-linear tensor category. In characteristic $p > 0$, the category of bundles with an integrable connection is only $\mathcal{O}_{X^{(1)}}$-linear, where $X^{(1)}$ is the relative Frobenius twist of $X$, and the notion is too weak. On the other hand, in characteristic 0, the category of bundles with a flat connection is the same as the category of $\mathcal{O}_X$-coherent $\mathcal{D}_X$-modules. In characteristic $p > 0$, $\mathcal{O}_X$-coherent $\mathcal{D}_X$-modules over a smooth variety $X$ defined over a field $k$ form an abelian, rigid, $k$-linear tensor category (see [Gi]). It is equivalent to the category of stratified bundles. It bears strong analogies with the category of bundles with an integrable connection in characteristic 0. For example, if $X$ is projective smooth over an algebraically closed field, the triviality of the étale fundamental group forces all such $\mathcal{O}_X$-coherent $\mathcal{D}_X$-modules to be trivial (\cite{EM}).

So we raise the question 1: let $f : X \to S$ be a smooth projective morphism of smooth connected varieties, defined over an algebraically closed characteristic $p > 0$ field, let $(E, \nabla)$ be a stratified bundle relative to $S$, such that for all closed point $s$ of some non-trivial open $U \subset S$, the stratified bundle $(E, \nabla)|_{X_s}$ is trivialized by a finite étale cover of $X_s := X \times_S s$. Is it the case that the stratified bundle $(E, \nabla)|_{X_{\eta}}$ is trivialized by a finite étale cover of $X_{\eta}$?

In this form, this is not true. Y. Laszlo [L3] constructed a one dimensional non-trivial family of bundles over a curve over $\bar{F}_2$ which is fixed by the square of Frobenius, as a (negative) answer to a question of J. de Jong concerning the behavior of representations of the étale fundamental group over a finite field $\bar{F}_q$, $q = p^n$, with values in $GL(r, \bar{F}(i))$, where $\bar{F} \supset \bar{F}_2$ is a finite extension. In fact, Laszlo’s example yields also a counter-example to the question as stated above. We explain this in Sections[1]and[4] (see Corollary 4.3). We remark that if $E$ is a bundle on $X$, such that the bundle $E|_{X_s}$ is stable, numerically flat (see Definition 3.2) and moves in the moduli, then $E_\eta$ cannot be trivialized by a finite étale cover (see Proposition 4.4). In contrast, we show that if the family $X \to S$ is trivial (as it is in Laszlo’s example), thus $X = Y \times_k S$, if $k$ is algebraically closed, and if $(F^p_\mathcal{E} \times \text{id}_{Y})^*(E)|_{Y \times_S \mathbb{A}^1} \cong E|_{Y \times_S \mathbb{A}^1}$ for all closed points $s$ of some non-trivial open in $S$ and some fixed natural number $n$, then the moduli points of $E|_{Y \times_S \mathbb{A}^1}$ are constant (see Proposition 4.4). Here $F_\mathcal{E} : Y \to Y$ is the absolute Frobenius of $Y$. In Laszlo’s example, one does have $(F^p_\mathcal{E} \times \text{id}_{Y})^*(E)|_{Y \times_S \mathbb{A}^1} \cong E|_{Y \times_S \mathbb{A}^1}$ but
only over $k = \mathbb{F}_2$ (i.e., $S$ is also defined over $\mathbb{F}_2$). When one extends the family to the algebraic closure of $\mathbb{F}_2$, to go from the absolute Frobenius over $\mathbb{F}_2$, that is the relative Frobenius over $k$, to the absolute one, one needs to replace the power 2 with a higher power $n(s)$, which depends on the field of definition of $s$, and is not bounded.

So we modify question 1 in question 2: let $f : X \to S$ be a smooth projective morphism of smooth connected varieties, defined over an algebraically closed characteristic field $k$ of characteristic $p > 0$, let $E$ be a bundle such that for all closed points $s$ of some non-trivial open $U \subset S$, the bundle $E|_{X_s}$ is trivialized by a finite Galois étale cover of $X_s := X \times_S s$ of order prime to $p$. Is it the case that the bundle $E|_{X_{\bar{\eta}}}$ is trivialized by a finite étale cover of $X_{\bar{\eta}}$?

The answer is nearly yes: it is the case if $k$ is not algebraic over its prime field (Theorem 5.1). If $k = \mathbb{F}_p$, it might be wrong (Remarks 5.4), but what remains true is that there exists a finite étale cover of $X_{\bar{\eta}}$ over which the pull-back of $E$ is a direct sum of line bundles (Theorem 5.1). The assumption on the degrees of the Galois covers of $X_s$ trivializing $E|_{X_s}$ is necessary (as follows from Laszlo’s example) and it allows us to apply Brauer-Feit’s theorem in place of Jordan’s theorem used by André. However, there is no direct substitute for Simpson’s moduli spaces of flat bundles. Instead, we use the moduli spaces constructed in [La1] and we carefully analyze subloci containing the points of interest, that is the numerically flat bundles. The necessary material needed on moduli is gathered in Section 3.

Finally we raise the general question 3: let $f : X \to S$ be a smooth projective morphism of smooth connected varieties, defined over an algebraically closed characteristic $p > 0$ field, let $(E, \nabla)$ be a stratified bundle relative to $S$, such that for all closed points $s$ of some non-trivial open $U \subset S$, the stratified bundle $(E, \nabla)|_{X_s}$ is trivialized by a finite Galois étale cover of $X_s := X \times_S s$ of order prime to $p$. Is it the case that the bundle $(E, \nabla)|_{X_{\bar{\eta}}}$ is trivialized by a finite étale cover of $X_{\bar{\eta}}$?

We give the following not quite complete answer. If the rank of $E$ is 1, (in which case the assumption on the degrees of the Galois covers is automatically fulfilled), then the answer is yes provided $S$ is projective, and for any $s \in U$, Pic$(X_s)$ is reduced (see Theorem 7.1). The proof relies on (a variant of) an idea of M. Raynaud [Ra], using the height function associated to a symmetric line bundle (that is the reason for our assumption on $S$) on the abelian scheme and its dual, to show that an infinite Verschiebung-divisible point has height equal to 0 (Theorem 6.2). If $E$ has any rank, then the answer is yes if $k$ is not $\mathbb{F}_p$ (Theorem 7.2). In general, there is a prime to $p$-order Galois cover of $X_{\bar{\eta}}$ such that the pull-back of $E$ becomes a sum of stratified line bundles (Theorem 7.2).

Acknowledgements: The first author thanks Michel Raynaud for the fruitful discussions in November 2009, which are reflected in [Ra] and in Section 6. The first author thanks Johan de Jong for a beautiful discussion in November 2010 on the content of [EM], where she suggested question 1 to him, and where he replied that Laszlo’s example should contradict this, and that this should be better understood. The second author would like to thank Stefan Schröer for destroying his naive hopes concerning
Néron models of Frobenius twists of an abelian variety. We thank Damian Rössler for discussions on $p$-torsion on abelian schemes over functions fields. We thank the referee of a first version of the article. He/she explained to us that the dichotomy in Theorem 5.12) and in Theorem 7.22) should be $\mathbb{F}_p$ or not rather that countable or not, thereby improving our result.

1 Preliminaries on relative stratified sheaves

Let $S$ be a scheme of characteristic $p$ (i.e., $\mathcal{O}_S$ is an $\mathbb{F}_p$-algebra). By $F^r_S : S \to S$ we denote the $r$-th absolute Frobenius morphism of $S$ which corresponds to the $p^r$-th power mapping on $\mathcal{O}_S$.

If $X$ is an $S$-scheme, we denote by $X^{(r)}_S$ the fiber product of $X$ and $S$ over the $r$-th Frobenius morphism of $S$. If it is clear with respect to which structure $X$ is considered, we simplify the notation to $X^{(r)}$. Then the $r$-th absolute Frobenius morphism of $X$ induces the relative Frobenius morphism $F^r_{X/S} : X \to X^{(r)}$. In particular, we have the following commutative diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{F^r_X} & X^{(r)} \\
\downarrow{X^{(r)}_S} & & \downarrow{W^{(r)}_X} \\
S & \xrightarrow{F^r_S} & S \\
\end{array}
\]

which defines $W^r_{X/S} : X^{(r)} \to X$.

Making $r = 1$ and replacing $X$ by $X^{(i)}$, this induces the similar diagram

\[
\begin{array}{ccc}
X^{(i)} & \xrightarrow{F^r_{X^{(i)}}} & X^{(i+1)} \\
\downarrow{X^{(i+1)}_S} & & \downarrow{W^{(i+1)}_{X^{(i)}}} \\
S & \xrightarrow{F^r_{X^{(i)}}} & S \\
\end{array}
\]

We assume that $X/S$ is smooth. A relative stratified sheaf on $X/S$ is a sequence $\{E_i, \sigma_i\}_{i \in \mathbb{N}}$ of locally free coherent $\mathcal{O}_{X^{(i)}}$-modules $E_i$ on $X^{(i)}$ and isomorphisms $\sigma_i : F^r_{X^{(i)}}E_i \to E_i$ of $\mathcal{O}_{X^{(i)}}$-modules. A morphism of relative stratified sheaves $\{\alpha_i : E_i \rightarrow E'_i\}$ is a sequence of $\mathcal{O}_{X^{(i)}}$-linear maps $\alpha_i : E_i \to E'_i$ compatible with the $\sigma_i$, that is such that $\sigma'_i \circ F^r_{X^{(i)}} \alpha_{i+1} = \alpha_i \circ \sigma_i$.

This forms a category Strat$(X/S)$, which is contravariant for morphisms $\phi : T \to S$: to $\{E_i, \alpha_i\} \in \text{Start}(X/S)$ one assigns $\phi^*\{E_i, \alpha_i\} \in \text{Strat}(X \times_ST/T)$ in the obvious way: $\phi$ induces $1_{X^{(i)}_X} \times \phi : X^{(i)}_X \times_ST \to X^{(i)}_X$ and $(\phi^*\{E_i, \alpha_i\})_i = \{(1_{X^{(i)}_X} \times \phi)^*E_i, (1_{X^{(i)}_X} \times \phi)^*\sigma_i\}$.
If \( S = \text{Spec} \ k \) where \( k \) is a field, \( \text{Strat}(X/k) \) is an abelian, rigid, tensor category. Giving a rational point \( x \in X(k) \) defines a fiber functor via \( \omega_x : \text{Strat}(X/k) \to \text{Vec}_k \), \( \omega_x(\{E, \sigma_i\}) = (E_0) \), in the category of finite dimensional vector spaces over \( k \), thus a \( k \)-group scheme \( \pi_*(\text{Strat}(X/k), \omega_x) = \text{Aut}^\circ(\omega_x) \). Tannaka duality implies that \( \text{Strat}(X/k) \) is equivalent via \( \omega_x \) to the representation category of \( \pi_*(\text{Strat}(X/k), \omega_x) \) with values in \( \text{Vec}_k \). For any object \( E := \{E_i, \sigma_i\} \in \text{Strat}(X/k) \), we define its monodromy group to be the \( k \)-affine group scheme \( \pi(E, \omega_x) \), where \( \langle E \rangle \subset \text{Strat}(X/k) \) is the full subcategory spanned by \( E \). This is the image of \( \pi(\text{Strat}(X/k), \omega_x) \) in \( GL(\omega_x(\langle E \rangle)) \) ([DM Proposition 2.21 a]). We denote by \( I_{X/k} \in \text{Strat}(X/k) \) the trivial object, with \( E' = \mathcal{O}_{X^{(i)}} \) and \( \sigma_i = \text{Identity} \).

**Lemma 1.1.** With the notation above

1) If \( h : Y \to X \) is a finite étale cover such that \( h^*E \) is trivial, then \( h_! \mathcal{L}_{Y/k} \)

has finite monodromy group and one has a faithfully flat homomorphism

\[
\pi(h_! \mathcal{L}_{Y/k}, \omega_x) \to \pi(\langle E \rangle, \omega_x).
\]

Thus in particular, \( E \) has finite monodromy group as well.

2) If \( E \in \text{Strat}(X/k) \) has finite monodromy group, then there exists a \( \pi((E), \omega_x) \)-torsor \( h : Y \to X \) such that \( h^*E \) is trivial in \( \text{Strat}(Y/k) \). Moreover, one has an isomorphism

\[
\pi(h_! \mathcal{L}_{Y/k}, \omega_x) \xrightarrow{\cong} \pi((E), \omega_x).
\]

**Proof.** We first prove 2). Assume \( \pi((E), \omega_x) = : G \) is a finite group scheme over \( k \). One applies Nori’s method [No, Chapter I, II]: the regular representation of \( G \) on the affine \( k \)-algebra \( k[G] \) of regular function defines the Artin \( k \)-algebra \( k[G] \) as a \( k \)-algebra object of the representation category of \( G \) on finite dimensional \( k \)-vector spaces, (such that \( k \subset k[G] \) is the maximal trivial subobject). Thus by Tannaka duality, there is an object \( \mathcal{A} = (A^i, \tau_i) \in \text{Strat}(X/k) \), which is an \( I_{X/k} \)-algebra object, (such that \( I_{X/k} \subset \mathcal{A} \) is the maximal trivial subobject). We define \( h_i : Y_i = X \to X_{(i)} \). Then the isomorphism \( \tau_i \) yields an \( \mathcal{O}_{X^{(i)}} \)-isomorphism between \( Y_{(i)} \xrightarrow{h_{(i)}} X^{(i)} \) and \( Y_i \xrightarrow{h_i} X_{(i)} \), (see, e.g., [SGAS Exposé XV, §1, Proposition 2]), and via this isomorphism, \( \mathcal{A} \) is isomorphic to \( h_* \mathcal{L}_{Y/k} \). On the other hand, \( \omega_x(\mathcal{A}) \) is a sub \( G \)-representation of \( k[G] \) for some \( n \in \mathbb{N} \), thus \( E \subset \mathcal{A}^{\otimes n} \in \text{Strat}(X/k) \), thus there is an inclusion \( E \subset (h_! \mathcal{L}_{Y/k})^{\otimes n} \in \text{Strat}(X/k) \), thus \( h^*E \subset (h^*h_! \mathcal{L}_{Y/k})^{\otimes n} \in \text{Strat}(Y/k) \). Since \( h^*h_! \mathcal{L}_{Y/k} \) is isomorphic to \( k[G] \) in \( \text{Strat}(Y/k) \) (recall that by [DM Proposition 13], \( G \) is an étale group scheme), then \( h^*E \) is isomorphic to \( \otimes^r \mathcal{L}_{Y/k} \), where \( r \) is the rank of \( E \). This shows the first part of the statement, and shows the second part as well: indeed, \( E \) is then a subobject of \( h_* \mathcal{L}_{Y/k} \) thus \( \mathcal{A} \subset \langle h_* \mathcal{L}_{Y/k} \rangle \) is a full subcategory. One applies [DM Proposition 2.21 a]) to show that the induced homomorphism \( \pi(h_* \mathcal{L}_{Y/k}, \omega_x) \to \pi((E), \omega_x) = G \) is faithfully flat. So \( \pi((h_* \mathcal{L}_{Y/k}, \omega_x) \) acts on \( \omega_x(h_* \mathcal{L}_{Y/k}) = k[G] \) via its quotient \( G \) and the regular representation \( G \subset GL(k[G]) \). Thus the homomorphism is an isomorphism.

We show 1). Assume that there is a finite étale cover \( h : Y \to X \) such that \( h^*E \) is isomorphic in \( \text{Strat}(Y/k) \) to \( \otimes^r \mathcal{L}_{Y/k} \) where \( r \) is the rank of \( E \). Then \( E \subset \otimes^r h_* \mathcal{L}_{Y/k} \), thus \( \pi(h_* \mathcal{L}_{Y/k}, \omega_x) \to \pi((E), \omega_x) \) is faithfully flat [DM loc. cit.,] so we are reduced to showing that \( h_* \mathcal{L}_{Y/k} \) has finite monodromy. But, by the same argument as on \( E \),
any of its objects of rank $r'$ lies in $\oplus_r h^r \mathbb{L}^r_{F/k}$. So we apply [DM Proposition 2.20 a)] to conclude that the monodromy of $h_{\mathbb{L}}^r_{F/k}$ is finite.

**Corollary 1.2.** With the notations as in [7] if $E \in \text{Strat}(X/k)$ has finite monodromy group, then for any field extension $K \supset k$, $E \otimes K \in \text{Strat}(X \otimes K/K)$ has finite monodromy group.

Let $E$ be an $\mathcal{O}_X$-module. We say that $E$ has a stratification relative to $S$ if there exists a relative stratified sheaf $\{E_i, \sigma_i\}$ such that $E_0 = E$.

Let us consider the special case $S = \text{Spec} k$, where $k$ is a perfect field, and $X/k$ is smooth. An (absolute) stratified sheaf on $X$ is a sequence $\{E_i, \sigma_i\}_{i \in \mathbb{N}}$ of coherent $\mathcal{O}_X$-modules $E_i$ on $X$ and isomorphisms $\sigma_i : F_q^i E_{i+1} \to E_i$ of $\mathcal{O}_X$-modules.

As $k$ is perfect, the $W_{X,0}$ are isomorphisms, thus giving an absolute stratified sheaf is equivalent to giving a stratified sheaf relative to $\text{Spec} k$.

We now go back to the general case and we assume that $S$ is an integral $k$-scheme, where $k$ is a field. Let us set $K = k(S)$ and let $\eta : \text{Spec} K \to S$ be the generic point of $S$. Let us fix an algebraic closure $\overline{k}$ of $k$ and let $\overline{\eta}$ be the corresponding generic geometric point of $S$.

By contravariance, a relative stratified sheaf $\{E_i, \sigma_i\}$ on $X/S$ restricts to a relative stratified sheaf $\{E_i, \sigma_i\}_{|X_s}$ in fibers $X_s$ for $s$ a point of $S$. We are interested in the relation between $\{E_i, \sigma_i\}_{|X_s}$ and $\{E_i, \sigma_i\}_{|X_s}$ for closed points $s \in |S|$. More precisely, we want to understand under which assumptions the finiteness of $\{E_i, \sigma_i\}_{|X_s}$ for all closed points $s \in |S|$ implies the finiteness of $\{E_i, \sigma_i\}_{|X_\eta}$. Recall that finiteness of $E \subset \text{Strat}(X)$ means that all objects of $\langle E \rangle$ are subquotients in $\text{Strat}(X)$ of direct sums of a single object, which is equivalent to saying that after the choice of a rational point, the monodromy group of $E$ is finite ([DM Proposition 2.20 (a)]).

Let $X$ be a smooth variety defined over $\mathbb{F}_q$ with $q = p^r$. For all $n \in \mathbb{N} \setminus \{0\}$, one has the commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\phi^m} & X^{(m)} \\
\downarrow \text{Spec } \mathbb{F}_q & & \downarrow \text{Spec } \mathbb{F}_q \\
\text{Spec } \mathbb{F}_q & \xrightarrow{\phi^m_{|\mathbb{F}_q}} & \text{Spec } \mathbb{F}_q
\end{array}
\]

which allows us to identify $X^{(m)}$ with $X$ (as an $\mathbb{F}_q$-scheme).

Let $S$ be an $\mathbb{F}_q$ connected scheme, with field of constants $k$, i.e. $k$ is the normal closure of $\mathbb{F}_q$ in $H^0(S, \mathcal{O}_X)$. We define $X_S := X \times_{\mathbb{F}_q} S$.

**Proposition 1.3.** Let $E$ be a vector bundle on $X_S$. Assume that there exists a positive integer $n$ such that we have an isomorphism

\[
\tau : ((F^r \times_{\mathbb{F}_q} \text{id})^n)^* E \simeq E.
\]

Then $E$ has a natural stratification $E\tau = \{E_i, \sigma_i\}$, $E_0 = E$ relative to $S$. 

\[
(1)
\]
Proof. We define
\[ E_{rn} = (W_{X/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E. \]
Then we use the factorization
\[ \begin{array}{cccccc}
X & \xrightarrow{F_X/F_q} & X(1) & \xrightarrow{F_X/(1)/F_q} & X(rn-1) & \xrightarrow{F_X/(rn)/F_q} & X(rn) \\
& & & & \downarrow & \downarrow & \\
& & & & \text{Spec } F_q & \downarrow & \\
\end{array} \]
(4)
of \( F_{X/F_q}^m \) and we define
\[ E_{nr-1} = (F_{X/(rn-1)/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E_{rn}, \ldots, E_1 = (F_{X/(1)/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E_2 \]
(5)
with identity isomorphisms \( \sigma_{nr-1}, \ldots, \sigma_1 \). Then we use the isomorphism \( \tau \) to define
\[ \sigma_0 : E \simeq (F_{X/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E_1. \]
(6)
Assume we constructed the bundles \( E_i \) on \( X^{(i)} \) for all \( i \leq arn \) for some integer \( a \geq 1 \).
We now replace the diagram (1) by the diagram
\[ \begin{array}{cccccc}
X^{(arn)} & \xrightarrow{F_{X^{(arn)}/F_q}^m} & X^{((a+1)rn)} & \xrightarrow{W_{X^{(arn)}/F_q}^m} & X^{(arn)} \\
& & & & \downarrow & \downarrow & \\
& & & & \text{Spec } F_q & \downarrow & \\
\end{array} \]
(7)
We then define
\[ E_{(a+1)rn} = (W_{X^{(arn)}/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E_{arn} \]
(8)
(which is equal to \( E \) under identification of \( X^{(arn)} \) with \( X \)). Then we use the factorization
\[ \begin{array}{cccccc}
X^{(arn)} & \xrightarrow{F_{X^{(arn)}/F_q}^m} & X^{(arn+1)} & \xrightarrow{F_{X^{(arn+1)}/F_q}^m} & \ldots & \xrightarrow{F_{X^{((a+1)rn-1)/F_q}^m}} & X^{((a+1)rn-1)} & \xrightarrow{F_{X^{((a+1)rn)/F_q}^m}} & X^{((a+1)rn)} \\
& & & & \downarrow & \downarrow & \downarrow & \downarrow & \\
& & & & \text{Spec } F_q & \downarrow & \\
\end{array} \]
(9)
of \( F_{X^{(arn)}/F_q}^m \) to define
\[ E_{(a+1)rn-1} = (F_{X^{((a+1)rn-1)/F_q}^m} \times \mathbb{F}_q^{\text{id}_S})^* E_{(a+1)rn}, \ldots, \]
\[ E_{arn+1} = (F_{X^{(arn+1)}/F_q}^m \times \mathbb{F}_q^{\text{id}_S})^* E_{arn+2} \]
(10)
with identity isomorphisms \( \sigma_{(a+1)nr-1} \), \ldots, \( \sigma_{arn+1} \). Then we again use \( \tau \) to define

\[
\sigma_{arn} : E_{arn} \cong (F_{\omega}^{\infty})^{*}E_{arn+1}. 
\]

(11)

The above construction and [Gi] Proposition 1.7 imply

**Proposition 1.4.** Assume in addition to (2) that \( X \) is proper and \( \mathbb{F}_q \subset k \subset \overline{\mathbb{F}}_q \). Fix a rational point \( x \in X_0(k) \). Then for any closed point \( s \in |S| \), the Tannaka group scheme 
\[
\pi(\mathbb{E}_S, \omega_S(k,s)) \text{ of } \mathbb{E}_S := \mathbb{E}_X\big|_S \text{ over the residue field } k(s) \text{ of } s \text{ is finite.}
\]

**Proof.** The bundle \( E \) is base changed of a bundle \( E^0 \) defined over \( X \times_{\mathbb{F}_q} S_0 \) for some form \( S_0 \) of \( S \) defined over a finite extension \( \mathbb{F}_q' \) of \( \mathbb{F}_q \) such that \( x \) is base change of an \( \mathbb{F}_q' \)-rational point \( x_0 \) of \( X \times_{\mathbb{F}_q} S_0 \). We can also assume that \( \tau \) comes by base change from \( \tau_0 : ((F^r \times_{\mathbb{F}_q} id_{S_0})^0)^0 \cong E^0 \). Proposition 1.3 yields then a relative stratification \( \mathbb{E}_0 \circlearrowleft = (E^0_0, \alpha_0^0) \) of \( E^0 \) defined over \( \mathbb{F}_q' \), with \( E_i = E^0_0 \circlearrowleft F_0^i \). A closed point \( s \) of \( S = S_0 \times_{\mathbb{F}_q} k \) is a base change of some closed point \( s_0 \) of \( S_0 \) of degree \( b \) say over \( \mathbb{F}_q'^b \). By Corollary 1.2 we just have to show that \( \pi(\mathbb{E}_S, \omega_S(k_0)) \) is finite. So we assume that \( k = \mathbb{F}_q \), \( S = S_0 \), \( s = s_0 \). The underlying bundles of \( \mathbb{E}_S \) and \( \mathbb{E}_S' \) are by construction all isomorphic for \( m = ab \). Thus by [Gi] Proposition 1.7, \( \mathbb{E}_\tau \cong \mathbb{E}_{\tau^m} \) in \( \text{Strat}(X/k) \). But this implies that \( F_{\mathbb{F}_q}'(\mathbb{E}_\tau) \cong \mathbb{E}_{\tau^m} \). Thus \( E \) is algebraically trivializable on the Lang torsor \( h : Y \to X \times_{\mathbb{F}_q} \mathbb{F}_q' \) and the bundles \( E_i \) are trivializable on \( Y \times_{X \times_{\mathbb{F}_q} \mathbb{F}_q'} X^{(i)} = Y^{(i)}/\mathbb{F}_q' \). Thus the stratified bundle \( h^*\mathbb{E}_\tau \) on \( Y \) relative to \( \mathbb{F}_q' \) is trivial. We apply Lemma 1.4 to finish the proof.

2 Étale trivializable bundles

Let \( X \) be a smooth projective variety over an algebraically closed field \( k \). Let \( F_X : X \to X \) be the absolute Frobenius morphism.

A locally free sheaf on \( X \) is called étale trivializable if there exists a finite étale covering of \( X \) on which \( E \) becomes trivial. Note that if \( E \) is étale trivializable then it is numerically flat (see Definition 2.2 and the subsequent discussion). In particular, stability and semistability for such bundles are independent of a polarization (and Gieseker and slope stability and semistability are equivalent). More precisely, such \( E \) is stable if and only if it does not contain any locally free subsheaves of smaller rank and degree 0 (with respect to some or equivalently to any polarization).

**Proposition 2.1.** (see [S]) If there exists a positive integer \( n \) such that \( (F_X^n)^*E \cong E \) then \( E \) is étale trivializable. Moreover, if \( k = \overline{\mathbb{F}}_p \) then \( E \) is étale trivializable if and only if there exists a positive integer \( n \) and an isomorphism \( (F_X^n)^*E \cong E \).

**Proposition 2.2.** (see [BD]) If there exists a finite degree \( d \) étale Galois covering \( f : Y \to X \) such that \( f^*E \) is trivial and \( E \) is stable, then one has an isomorphism \( \alpha : (F_X^d)^*E \cong E \).
As a corollary we see that a line bundle on $X/k$ is étale trivializable if and only if it is torsion of order prime to $p$. One implication follows from the above proposition. The other one follows from the fact that $(F^i_k)^*L \simeq L$ is equivalent to $L^{0(p^i-1)} \simeq \mathcal{O}_X$ and for any integer $n$ prime to $p$ we can find $d$ such that $p^d - 1$ is divisible by $n$.

We recall that if $E$ is any vector bundle on $X$ such that there is a $d \in \mathbb{N} \setminus \{0\}$ and an isomorphism $\alpha : (F^i_k)^*E \cong E$, then $E$ carries an absolute stratified structure $E_{\alpha}$, i.e. a stratified structure relative to $\mathbb{F}_p$ by the procedure of Proposition 1.3. On the other hand, any stratified stratified structure $\{E_i, \sigma_i\}$ relative to $\mathbb{F}_p$ induces in an obvious way a stratified structure relative to $k$: the absolute Frobenius $F^q : X \to X$ factors through $W^q_{X/k} : X^{(n)} \to X$, so $\{W^q_{X/k}\}^*E_n, (W^q_{X/k})^* \sigma_n\}$ is the relative stratified structure, denoted by $E_{\alpha/k}$. Proposition 2.2 together with Lemma 1.1 show

**Corollary 2.3.** Under the assumptions of Proposition 2.2 we can take $d = \text{length}_k(\pi((E_{\alpha/k}, \sigma_h))).$

Let us also recall that there exist examples of étale trivializable bundles such that $(F^i_k)^*E \not\cong E$ for every positive integer $n$ (see Laszlo’s example in [BD]).

**Proposition 2.4.** (Deligne; see [Ls] 3.2) Let $X$ be an $\mathbb{F}_p$-scheme. If $G$ is a connected linear algebraic group defined over a finite field $\mathbb{F}_p$ then the embedding $G(\mathbb{F}_p) \hookrightarrow G$ induces an equivalence of categories between the category of $G(\mathbb{F}_p)$-torsors on $X$ and $G$-torsors $P$ over $X$ with an isomorphism $(F^q_k)^*P \simeq P$. In particular, if $G$ is a connected reductive algebraic group defined over an algebraically closed field $k$ and $P$ is a principal $G$-bundle on $X/k$ such that there exists an isomorphism $(F^q_k)^*P \simeq P$ for some natural number $n > 0$, then there exists a Galois étale cover $f : Y \to X$ with Galois group $G(\mathbb{F}_p)$ such that $f^*P$ is trivial. Indeed, every reductive group has a $\mathbb{Z}$-form so we can use the above proposition.

## 3 Preliminaries on Relative Moduli Spaces of Sheaves

Let $S$ be a scheme of finite type over a universally Japanese ring $R$. Let $f : X \to S$ be a projective morphism of $R$-schemes of finite type with geometrically connected fibers and let $\mathcal{O}_X(1)$ be an $f$-very ample line bundle.

A family of pure Gieseker semistable sheaves on the fibres of $X_T = X \times_S T \to T$ is a $T$-flat coherent $\mathcal{O}_{X_T}$-module $E$ such that for every geometric point $t$ of $T$ the restriction of $E$ to the fibre $X_t$ is pure (i.e., all its associated points have the same dimension) and Gieseker semistable (which is semistability with respect to the growth of the Hilbert polynomial of subsheaves defined by $\mathcal{O}_{X_T}(1)$ (see [HL] 1.2]). We introduce an equivalence relation $\sim$ on such families in the following way. $E \sim E'$ if and only if there exist filtrations $0 = E_0 \subset E_1 \subset \cdots \subset E_m = E$ and $0 = E'_0 \subset E'_1 \subset \cdots \subset E'_m = E'$ by coherent $\mathcal{O}_{X_T}$-modules such that $\oplus_{i=0}^m E_i / E_{i-1}$ is a family of pure Gieseker semistable sheaves on the fibres of $X_T$ and there exists an invertible sheaf $L$ on $T$ such that $\oplus_{i=1}^m E'_i / E'_{i-1} \simeq (\oplus_{i=1}^m E_i / E_{i-1}) \otimes \mathcal{O}_T L$.

Let us define the moduli functor

$$\mathcal{M}_p(X/S) : \text{Sch}/S^{op} \to \text{Sets}$$
from the category of locally noetherian schemes over $S$ to the category of sets by

$$\mathcal{M}_P(X/S)(T) = \left\{ \begin{array}{l}
\sim \text{ equivalence classes of families of pure Gieseker} \\
\text{semistable sheaves on the fibres of } T \times_S X \to T, \\
\text{which have Hilbert polynomial } P.
\end{array} \right\}.$$ 

Then we have the following theorem (see [La1 Theorem 0.2]).

**Theorem 3.1.** Let us fix a polynomial $P$. Then there exists a projective $S$-scheme $M_P(X/S)$ of finite type over $S$ and a natural transformation of functors

$$\theta : \mathcal{M}_P(X/S) \to \text{Hom}_S(\cdot, M_P(X/S)),$$

which uniformly corepresents the functor $\mathcal{M}_P(X/S)$. For every geometric point $s \in S$ the induced map $\theta(s)$ is a bijection. Moreover, there is an open scheme $M^s_k(P) \subset M_P(X/S)$ that universally corepresents the subfunctor of families of geometrically Gieseker stable sheaves.

Let us recall that $M_P(X/S)$ uniformly corepresents $\mathcal{M}_P(X/S)$ means that for every flat base change $T \to S$ the fiber product $M_P(X/S) \times_S T$ corepresents the fiber product functor $\text{Hom}_S(\cdot, T) \times_{\text{Hom}_S(\cdot, S)} \mathcal{M}_P(X/S)$. For the notion of corepresentability, we refer to [HL] Definition 2.2.1. In general, for every $S$-scheme $T$ we have a well defined morphism $M_P(X/S) \times_S T \to M_P(X_T/T)$ which for a geometric point $T = \text{Spec } k(s) \to S$ is bijection on points.

The moduli space $M_P(X/S)$ in general depends on the choice of polarization $\mathcal{O}_X(1)$.

**Definition 3.2.** Let $k$ be a field and let $Y$ be a projective $k$-variety. A coherent $\mathcal{O}_Y$-module $E$ is called numerically flat, if it is locally free and both $E$ and its dual $E^+ = \mathcal{H}^0(E, \mathcal{O}_Y)$ are numerically effective on $Y \otimes k$, where $k$ is an algebraic closure of $k$.

Assume that $Y$ is smooth. Then a numerically flat sheaf is strongly slope semistable of degree 0 with respect to any polarization (see [La2 Proposition 5.1]). But such a sheaf has a filtration with quotients which are numerically flat and slope stable (see [La2 Theorem 4.1]). Let us recall that a slope stable sheaf is Gieseker stable and any extension of Gieseker semistable sheaves with the same Hilbert polynomial is Gieseker semistable. Thus a numerically flat sheaf is Gieseker semistable with respect to any polarization.

Let $P$ be the Hilbert polynomial of the trivial sheaf of rank $r$. In case $S$ is a spectrum of a field we write $M_X(r)$ to denote the subscheme of the moduli space $M_P(X/k)$ corresponding to locally free sheaves. For a smooth projective morphism $X \to S$ we also define the moduli subscheme $M(X/S, r) \to S$ of the relative moduli space $M_P(X/S)$ as a union of connected components which contains points corresponding to numerically flat sheaves of rank $r$. Note that in positive characteristic numerical flatness is not an open condition. More precisely, on a smooth projective variety $Y$ with an ample divisor $H$, a locally free sheaf with numerically trivial Chern classes, that is with Chern classes $c_i$ in the Chow group of codimension $i$ cycles intersecting trivially $H^{\dim(Y) - i}$
for all \(i \geq 1\), is numerically flat if and only if it is strongly slope semistable (see [La2, Proposition 5.1]).

By definition for every family \(E\) of pure Gieseker semistable sheaves on the fibres of \(X_T\) we have a well defined morphism \(\varphi_E = \theta([E]) : T \to M_p(X/S)\), which we call a classifying morphism.

**Proposition 3.3.** Let \(X\) be a smooth projective variety defined over an algebraically closed field \(k\) of positive characteristic. Let \(S\) be a \(k\)-variety and let \(E\) be a rank \(r\) locally free sheaf on \(X \times_k S\) such that for every \(s \in S(k)\) the restriction \(E_s\) is Gieseker semistable with numerically trivial Chern classes. Assume that the classifying morphism \(\varphi_E : S \to M_k(r)\) is constant and for a dense subset \(S' \subset S(k)\) the bundle \(E_s\) is étale trivializable for \(s \in S'\). Then \(E_{\bar{s}}\) is étale trivializable.

**Proof.** If \(E_s\) is stable for some \(k\)-point \(s \in S\) then there exists an open neighbourhood \(U\) of \(\varphi_E(s)\), a finite étale morphism \(U' \to U\) and a locally free sheaf \(\mathcal{V}\) on \(X \times_k U'\) such that the pull backs of \(E\) and \(\mathcal{V}\) to \(X \times_k (\varphi_E^{-1}(U) \times U')\) are isomorphic (this is called existence of a universal bundle on the moduli space in the étale topology). But \(\varphi_E(S)\) is a point, so this proves that there exists a vector bundle on \(X\) such that \(E\) is its pull back by the projection \(X \times_k S \to X\). In this case the assertion is obvious.

Now let us assume that \(E_s\) is not stable for all \(s \in S(k)\). If \(0 = E_0^s \subset E_1^s \subset \ldots \subset E_m^s = E_s\) is a Jordan–Hölder filtration (in the category of slope semistable torsion free sheaves), then by assumption the isomorphism classes of semi-simplifications \(\oplus_{i=1}^{m} E_i^s / E_{i-1}^s\) do not depend on \(s \in S(k)\). Let \((r_1, \ldots, r_m)\) denote the sequence of ranks of the components \(E_i^s / E_{i-1}^s\) for some \(s \in S(k)\). Since there is only finitely many such sequences (they differ only by permutation), we choose some permutation that appears for a dense subset \(S' \subset S\).

Now let us consider the scheme of relative flags \(f : \text{Flag}(E/S; P_1, \ldots, P_m) \to S\), where \(P_i\) is the Hilbert polynomial of \(E_i^s\). By our assumption the image of \(f\) contains \(S'\). Therefore by Chevalley’s theorem it contains an open subscheme \(U\) of \(S\). Let us recall that the scheme of relative flags \(\text{Flag}(E[1\times_k U]; P_1, \ldots, P_m) \to U\) is projective. In particular, using Bertini’s theorem (\(k\) is algebraically closed) we can find a generically finite morphism \(W \to U\) factoring through this flag scheme. Let us consider pull back of the universal filtration \(0 = F_0 \subset F_1 \subset \ldots \subset F_m = E_W\) to \(X \times_k W\). Note that the quotients \(F_i = F_i / F_{i-1}\) are \(W\)-flat and by shrinking \(W\) we can assume that they are families of Gieseker stable locally free sheaves (since by assumption \(F_i\) is Gieseker stable and locally free for some points \(s \in W(k) \cap S'\)). This and the first part of the proof implies that \(E_{\bar{s}}\) has a filtration by subbundles such that the associated graded sheaf is étale trivializable. By Lemma 5.2 this implies that \(E_{\bar{s}}\) is étale trivializable. \(\square\)

4 Laszlo’s example

Let us describe Laszlo’s example of a line in the moduli space of bundles on a curve fixed by the second Verschiebung morphism (see [La, Section 3]).

Let us consider a smooth projective genus 2 curve \(X\) over \(\mathbb{F}_2\) with affine equation

\[y^2 + x(x+1)y = x^3 + x^2 + x.\]
In this case the moduli space $M_X(2, \mathcal{O}_X)$ of rank 2 vector bundles on $X$ with trivial determinant is an $\mathbb{P}^2$-scheme isomorphic to $\mathbb{P}^3$. The pull back of bundles by the relative Frobenius morphism defines the Verschiebung map

$$V : M_{X^{(1)}}(2, \mathcal{O}_{X^{(1)}}) \simeq \mathbb{P}^3 \dashrightarrow M_X(2, \mathcal{O}_X) \simeq \mathbb{P}^3$$

which in appropriate coordinates can be described as

$$[a : b : c : d] \mapsto [a^2 + b^2 + c^2 + d^2 : ab + cd : ac + bd : ad + bc].$$

The restriction of $V$ to the line $\Delta \cong \mathbb{P}^1$ given by $b = c = d$ is an involution and it can be described as $[a : b] \mapsto [a + b : b]$.

Using a universal bundle on the moduli space (which exists locally in the étale topology around points corresponding to stable bundles) and taking a finite covering $\Delta \rightarrow X$ we obtain the following theorem:

**Theorem 4.1.** ([Ls Corollary 3.2]) There exist a smooth quasi-projective curve $S$ defined over some finite extension of $\mathbb{F}_2$ and a locally free sheaf $E$ of rank 2 on $X \times S$ such that $(F^2 \times \text{id}_S)^*E \simeq E$, $\det E \simeq \mathcal{O}_{X \times S}$ and the classifying morphism $\varphi_E : S \rightarrow M_X(2, \mathcal{O}_X)$ is not constant. Moreover, one can choose $S$ so that $E_s$ is stable for every closed point $s$ in $S$.

Now note that the map $(F_2)^* : M_X(2, \mathcal{O}_X) \rightarrow M_X(2, \mathcal{O}_X)$ defined by pulling back bundles by the absolute Frobenius morphism can be described on $\Delta$ as $[a : b] \mapsto [a^2 + b^2 : b^2]$. In particular, the map $(F_2^\infty)^*|_{\Delta}$ is described as $[a : b] \mapsto [a^{2^n}, b^{2^n}]$. It follows that if a stable bundle $E$ corresponds to a modular point of $\Delta(\mathbb{P}^2_2) \setminus \Delta(\mathbb{P}^2_{2-1})$ (or, equivalently, $E$ is defined over $\mathbb{F}_2$) then $(F_2^m)^*E \simeq E$ and $(F_2^m)^*E \not\simeq E$ for $0 < m < 2n$.

This implies that for $k = \mathbb{F}_2$ and for every $s \in S(k)$, the bundle $E_s$ which is the restriction to $X \times \mathbb{F}_2$ of the bundle $E$ from Theorem 4.1 is étale trivializable.

Let $X, S$ be varieties defined over an algebraically closed field $k$ of positive characteristic. Assume that $X$ is projective. Let us set $K = k(S)$. Let $\bar{\eta}$ be a generic geometric point of $S$.

**Proposition 4.2.** Let $E$ be a bundle on $X_S = X \times_k S \rightarrow S$ which is numerically flat on the closed fibres of $X_S = X \times_k S \rightarrow S$. Assume that for some $s \in S$ the bundle $E_s$ is stable and the classifying morphism $\varphi_E : S \rightarrow M_X(r)$ is not constant. Then $E_{\bar{\eta}} = E|_{X_{\bar{\eta}}}$ is not étale trivializable.

**Proof.** Assume that there exists a finite étale cover $\pi' : Y' \rightarrow X_{\bar{\eta}}$ such that $(\pi')^*E_{\bar{\eta}} \simeq \mathcal{O}_{Y'}^{\oplus r}$. As $k$ is algebraically closed, one has the base change $\pi_1(X) \rightarrow \pi_1(X_{\bar{k}})$ for the étale fundamental group ([SGA1 Exp. X, Cor.1.8]), so there exists a finite étale cover $\pi : Y \rightarrow X$ such that $\pi = \pi \otimes \bar{k}$. Hence there exists a finite morphism $T \rightarrow U$ over some open subset $U$ of $S$, such that $\pi_T^*E_T$ is trivial where $\pi_T = \pi \times_k \text{id}_T : Y \times_k T \rightarrow X \times_k T$ and $E_T =$ pull back by $X \times_k T \rightarrow X \times_k U$ of $E|_{X \times_k U}$.

So for any $k$-rational point $t \in T$, one has $\pi_*E_t \subset \mathcal{O}_T^{\oplus r}$, where $r$ is the rank of $E$. Hence $E_t \subset \pi_\ast \mathcal{O}_T^{\oplus r}$. Hence $E_t \subset \pi_\ast \mathcal{O}_T^{\oplus r}$, i.e., all the bundles $E_t$ lie in one fixed bundle $\pi_\ast \mathcal{O}_T^{\oplus r}$. 
Since \( \pi \) is étale, the diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{F_Y} & Y \\
\downarrow{\pi} & & \downarrow{\pi} \\
X & \xrightarrow{F_X} & X
\end{array}
\]

is cartesian (see, e.g., \cite{SGA5} Exp. XIV, §1, Prop. 2). Since \( X \) is smooth, \( F_X \) is flat. By flat base change we have isomorphisms \( F_Y^*(\pi_*\mathcal{O}_Y) \cong \pi_*(F_Y^*\mathcal{O}_Y) \cong \pi_*\mathcal{O}_Y \). In particular, this implies that \( \pi_*\mathcal{O}_Y \) is strongly semistable of degree 0. Therefore if \( E_i \) is stable then it appears as one of the factors in a Jordan–Hölder filtration of \( \pi_*\mathcal{O}_Y \). Since the direct sum of factors in a Jordan–Hölder filtration of a semistable sheaf does not depend on the choice of the filtration, there are only finitely many possibilities for the isomorphism classes of stable sheaves \( E_i \) for \( i \in T(k) \).

It follows that in \( U \subset S \) there is an infinite sequence of \( k \)-rational points \( s_i \) with the property that \( E_{s_i} \) is stable (since stability is an open property) and \( E_{s_i} \cong E_{s_{i+1}} \). This contradicts our assumption that the classifying morphism \( \varphi_E \) is not constant.

**Corollary 4.3.** There exist smooth curves \( X \) and \( S \) defined over an algebraic closure \( k \) of \( \mathbb{P}^2 \) such that \( X \) is projective and there exists a locally free sheaf \( E \) on \( X \times_k S \to S \) such that for every \( s \in S(k) \), the bundle \( E_s \) is étale trivializable but \( E_{\bar{s}} \) is not étale trivializable. Moreover, on \( E \) there exists a structure of a relatively stratified sheaf \( \mathbb{E} \) such that for every \( s \in S(k) \), the bundle \( \mathbb{E}_s \) has finite monodromy but the monodromy group of \( \mathbb{E}_{\bar{s}} \) is infinite.

The second part of the corollary follows from Proposition 4.3. The above corollary should be compared to the following fact:

**Proposition 4.4.** Let \( X \) be a projective variety defined over an algebraically closed field \( k \) of positive characteristic. Let \( S \) be a \( k \)-variety and let \( E \) be a rank \( r \) locally free sheaf on \( X \times_k S \rightarrow S \). Assume that there exists a positive integer \( n \) such that for every \( s \in S(k) \) we have \( (F_X^n)^*E_s \cong E_s \), where \( F_X \) denotes the absolute Frobenius morphism. Then the classifying morphism \( \varphi_E : S \to M_X(r) \) is constant and \( E_{\bar{s}} \) is étale trivializable.

**Proof.** By Proposition 2.1 if \( (F_X^n)^*E_s \cong E_s \) then there exists a finite étale Galois cover \( \pi_i : Y_i \rightarrow X \) with Galois group \( G = \text{GL}_r(\mathbb{F}_p) \) such that \( \pi_i^*E_s \) is trivial (in this case it is essentially due to Lange and Stuhler; see \cite{LS}). This implies that \( E_s \subset \langle \pi_i \rangle, \pi_i^*E_s \cong (\langle \pi_i \rangle, \mathcal{O}_Y)^{\otimes r} \) and hence \( \text{gr}_{JH}E_s \subset (\text{gr}_{JH}(\pi_i, \mathcal{O}_Y))^{\otimes r} \).

Since \( X \) is proper, the étale fundamental group of \( X \) is topologically finitely generated and hence there exists only finitely many finite étale coverings of \( X \) of fixed degree (up to an isomorphism). This theorem is known as the Lang–Serre theorem (see \cite{LS} Théorème 4)). Let \( \mathcal{S} \) be the set of all Galois coverings of \( X \) with Galois group \( G \). Then for every closed \( k \)-point \( s \) of \( S \) the semi-simplification of \( E_s \) is contained in \( (\text{gr}_{JH} \alpha_* \mathcal{O}_Y)^{\otimes r} \) for some \( \alpha \in \mathcal{S} \). Therefore there are only finitely many possibilities for images of \( k \)-points \( s \) in \( M_X(r) \). Since \( S \) is connected, it follows that \( \varphi_E : S \to M_X(r) \) is constant.
The remaining part of the proposition follows from Proposition 3.3.

Note that by Proposition 4.2 together with Corollary 2.3, the monodromy groups of $E_s$ in Theorem 4.1 for $s \in S(k)$ are not uniformly bounded. In fact, only if $k$ is an algebraic closure of a finite field do we know that the monodromy groups of $E_s$ are finite because then $E_s$ can be defined over some finite subfield of $k$ and the isomorphism $(F^2)^* E_s \simeq E_s$ implies that for some $n$ we have $(F^n)^* E_s \simeq E_s$ (see the paragraph following Theorem 4.1).

Moreover, the above proposition shows that in Theorem 4.1, we cannot hope to replace $F$ with the absolute Frobenius morphism $F_X$.

5 Analogue of the Grothendieck-Katz conjecture in positive equicharacteristic

As Corollary 4.3 shows, the positive equicharacteristic version of the Grothendieck–Katz conjecture which requests a relatively stratified bundle to have finite monodromy group on the geometric generic fiber once it does on all closed fibers, does not hold in general. But one can still hope that it holds for a family of bundles coming from representations of the prime-to-$p$ quotient of the étale fundamental group. In this section we follow André’s approach [An, Théorème 7.2.2] in the equicharacteristic zero case to show that this is indeed the case.

Let $k$ be an algebraically closed field of positive characteristic $p$. Let $f : X \to S$ be a smooth projective morphism of $k$-varieties (in particular, integral $k$-schemes). Let $\eta$ be the generic point of $S$. In particular, $X_{\eta}$ is smooth (see [SGA1, Defn 1.1]).

**Theorem 5.1.** Let $E$ be a locally free sheaf of rank $r$ on $X$. Let us assume that there exists a dense subset $U \subset S(k)$ such that for every $s \in U$, there is a finite étale covering $\pi_s : Y_s \to X_s$ of Galois group of order prime-to-$p$ such that $\pi_s^* (E_s)$ is trivial.

1) Then there exists a finite Galois étale covering $\pi_\eta : Y_\eta \to X_\eta$ of order prime-to-$p$ such that $\pi_\eta^* E_\eta$ is a direct sum of line bundles.

2) If $k$ is not algebraic over its prime field and $U$ is open in $S$, then $E_\eta$ is étale trivializable on a finite étale cover $Z_\eta \to X_\eta$ which factors as a Kummer (thus finite abelian of order prime to $p$) cover $Z_\eta \to Y_\eta$ and a Galois cover $Y_\eta \to X_\eta$ of order prime to $p$.

**Proof.** Without loss of generality, shrinking $S$ if necessary, we may assume that $S$ is smooth. Moreover, by passing to a finite cover of $S$ and replacing $U$ by its inverse image, we can assume that $f$ has a section $\sigma : S \to X$.

By assumption for every $s \in U$ there exists a finite étale Galois covering $\pi_s : Y_s \to X_s$ with Galois group $\Gamma_s$ of order prime-to-$p$ and such that $\pi_s^* E_s$ is trivial. To these data one can associate a representation $\rho_s : \pi_s^*(\text{trace of } \sigma(s)) \to \Gamma_s \subset \text{GL}_r(k)$ of the prime-to-$p$ quotient of the étale fundamental group.
By the Brauer–Feit version of Jordan’s theorem (see [BF, Theorem]) there exist a constant $j(r)$ such that $\Gamma_s$ contains an abelian normal subgroup $A_s$ of index $\leq j(r)$ (here we use assumption that the $p$-Sylow subgroup of $\Gamma$ is trivial).

For a $k$-point $s$ of $S$ we have a homomorphism of specialization
\[ \alpha_s : \pi_1(X, \sigma(\bar{\eta})) \to \pi_1(X, \sigma(s)), \]
which induces an isomorphism of the prime-to-$p$ quotients of the étale fundamental groups.

So for every $s \in U$ we can define the composite morphism
\[ \tilde{\rho}_s : \pi'_1(X, \sigma(\bar{\eta})) \xrightarrow{\alpha_s} \pi'_1(X, \sigma(s)) \xrightarrow{\tilde{\rho}} \Gamma_x \to \Gamma_x/A_s. \]

Let $K$ be the kernel of the canonical homomorphism $\pi_s : \pi_1(X, \sigma(\bar{\eta})) \to \pi_1(S, \bar{\eta})$, let $K'$ be its maximal pro-$p'$-quotient. Then by [SGA1, Exp. XIII, Proposition 4.3 and Exemples 4.4], one has $K' = \pi'_1(X, \sigma(\bar{\eta}))$, the maximal pro-$p'$-quotient of $\pi_1(X, \sigma(\bar{\eta}))$, and one has a short exact sequence
\[ \{1\} \to \pi'_1(X, \sigma(\bar{\eta})) \to \pi'_1(X, \sigma(\bar{\eta})) \xrightarrow{\pi} \pi_1(S, \bar{\eta}) \to \{1\}, \]
where $\pi'_1(X, \sigma(\bar{\eta}))$ is defined as the push-out of $\pi_1(X, \sigma(\bar{\eta}))$ by $K \to K'$.

Since $X_{\bar{\eta}}$ is proper, $\pi_1(X_{\bar{\eta}}, \sigma(\bar{\eta}))$ is topologically finitely generated. Therefore $\pi'_1(X, \sigma(\bar{\eta}))$ is also topologically finitely generated and hence it contains only finitely many subgroups of indices $\leq j(r)$. Let $G$ be the intersection of all such subgroups in $\pi'_1(X, \sigma(\bar{\eta}))$. It is a normal subgroup of finite index. Since $\ker(\tilde{\rho}_s)$ is a normal subgroup of index $\leq j(r)$ in $\pi'_1(X, \sigma(\bar{\eta}))$ we have
\[ G \subset \bigcap_{s \in U} \ker(\tilde{\rho}_s). \]

Now let us consider the commutative diagram
\[
\begin{array}{cccccc}
\pi_1(X_{\bar{\eta}}, \sigma(\bar{\eta})) & \longrightarrow & \pi_1(X, \sigma(\bar{\eta})) & \longrightarrow & \pi_1(S, \bar{\eta}) & \longrightarrow & \{1\} \\
\downarrow & & \downarrow & & \downarrow & & \\
\{1\} & \longrightarrow & \pi'_1(X_{\bar{\eta}}, \sigma(\bar{\eta})) & \longrightarrow & \pi'_1(X, \sigma(\bar{\eta})) & \longrightarrow & \pi_1(S, \bar{\eta}) & \longrightarrow & \{1\}
\end{array}
\]

Then $G \cdot \sigma(\pi_1(S, \bar{\eta})) \subset \pi'_1(X, \sigma(\bar{\eta}))$ is a subgroup of finite index. It is open by the Nikolov–Segal theorem [NS, Theorem 1.1]. So the pre-image $H$ of this subgroup under the quotient homomorphism $\pi_1(X, \sigma(\bar{\eta})) \to \pi_1(X, \sigma(\bar{\eta}))$ defines a finite étale covering $h : X' \to X$.

Let us take $s \in S(k)$. Since the composition
\[ H \subset \pi_1(X, \sigma(\bar{\eta})) \to \pi_1(X, \sigma(s)) \to \pi_1(S, s) \]
is surjective, the geometric fibres of $X' \to S$ are connected. Let us choose a $k$-point in $X'$ lying over $\sigma(s)$. By abuse of notation we call it $\sigma'(s)$. Similarly, let us choose a geometric point $\sigma'(\bar{\eta})$ of $X'_n$ lying over $\sigma(\bar{\eta})$. Then for any $s \in U$ we have the following commutative diagram:

\[
\begin{array}{cccc}
\pi'_1(X'_n, \sigma'(\bar{\eta})) & \xrightarrow{h_s} & \pi'_1(X_n, \sigma(\bar{\eta})) & \xrightarrow{G} \pi'_1(X_n, \sigma(\bar{\eta}))/G \\
\Downarrow \simeq & & \Downarrow \simeq & \\
\pi''_1(X'_n, \sigma'(s)) & \xrightarrow{h_s} & \pi''_1(X_n, \sigma(s)) & \xrightarrow{\Gamma_s/A_s} \Gamma_s/A_s
\end{array}
\]

This diagram shows that $\pi''_1(X'_n, \sigma'(s)) \to \Gamma_s$ factors through $A_s$ and hence $E'_s = (h^*E)_s$ is trivialized by a finite étale Galois covering. $\pi'_1(Y'_s \to X'_s)$ with an abelian Galois group of order prime to $p$, which is a subgroup of $A_s$. Since $E'_s \subset (\pi'_1)^*E'_s \simeq ((\pi'_1)^*O_{Y'_s})^{\oplus r}$, and $(\pi'_1)^*O_{Y'_s}$ is a direct sum of torsion line bundles of orders prime to $p$, it follows that for every $s \in U$ the bundle $E'_s$ is also a direct sum of torsion line bundles of order prime to $p$.

We consider the union $M(X'/S, r)$ of the components of $M_{\eta}(X'/S)$ containing moduli points of numerically flat bundles, as defined in Section 3. Let us consider the $S$-morphism $\psi : M(X'/S, 1)^{\times r} \to M(X'/S)$ given by $([L_1], \ldots, [L_r]) \mapsto [\square L]$ (in fact we give it by this formula on the level of functors; existence of the morphism follows from the fact that moduli schemes corepresent these functors). The bundle $E'$ gives us a section $\tau : S \to M(X'/S, r)$, and by the above for every $k$-rational point $s$ of $U$, the point $\tau(s)$ is contained in the image of $\psi$. Therefore $\tau(S)$ is contained in the image of $\psi$ as $\psi$ is projective (thus proper).

Let us consider the fibre product

\[
\begin{array}{ccc}
M(X'/S, 1)^{\times r} \times_{M(X'/S, r)} S & \to & S \\
\downarrow \tau & & \downarrow \tau \\
M(X'/S, 1)^{\times r} & \to & M(X'/S, r)
\end{array}
\]

Let us recall that in positive characteristic the canonical map $M(X' \times SS' \to S, r) \to M(X'/S, r) \times SS'$ need not be an isomorphism (although it is an isomorphism for $r = 1$). Anyway we can find an étale morphism $S' \to S$ over some non-empty open subset of $S$, such that there exists a map $\nu : S' \to M(X' \times SS' \to SS', 1)^{\times r}$ which composed with $M(X' \times SS' \to SS', 1)^{\times r} \to M(X' \times SS' \to SS, r) \to M(X'/S, r)$ gives the composition of $S' \to S$ with $\tau$. This shows that the pull back $E''_s$ of $E'$ to $X' \times SS'$ has a filtration whose quotients are line bundles which are of degree 0 on the fibres of $X' \times SS' \to SS'$.

Now let us note the following lemma:
Lemma 5.2. Let \( f : X \to S \) be a projective morphism of \( k \)-varieties. Let \( 0 \to G_1 \to G \to G_2 \to 0 \) be a sequence of locally free sheaves on \( X \). Assume that there exists a dense subset \( U \subset S(k) \) such that for each \( s \in U \) this sequence splits after restricting to \( X_s \). Then it splits on the fibre \( X_\eta \) over the generic point \( \eta \) of \( S \).

Proof. By shrinking \( S \) if necessary, we may assume that \( S \) is affine and the relative cohomology sheaf \( \mathcal{R}^1 p_* \mathcal{H}om(G_2, G_1) \) is locally free. The above short exact sequence defines a class \( \lambda \in \text{Ext}^1(G_2, G_1) \cong H^0(S, \mathcal{R}^1 f_* \mathcal{H}om(G_2, G_1)) \), such that \( \lambda(s) = 0 \) for every \( k \)-rational point \( s \) of \( U \). It follows that \( \lambda = 0 \) and hence the sequence is split over the generic point of \( S \).

Now let us note that on a smooth projective variety every short exact sequence of the form \( 0 \to G_1 \to G \to G_2 \to 0 \) in which \( G \) is a direct sum of line bundles of degree 0 and \( G_2 \) is a line bundle of degree 0 splits. So the filtration of \( E^n \) restricted to the closed fibers splits. Therefore the above lemma and easy induction show that \( E^n \eta \) is a direct sum of line bundles, where \( \eta' \) is the generic point of \( S' \). This shows the first part of the theorem.

To prove the second part of the theorem, we may assume that \( U = S \). Let us take a line bundle \( L \) on \( X \) such that for every \( k \)-rational point \( s \) the line bundle \( L_s \) is étale trivializable. We need to prove that there exists a positive integer \( n \) prime to \( p \) and such that \( L^{\otimes n}_\eta \cong \mathcal{O}_{X_\eta} \).

We thank the referee for showing us the following lemma.

Lemma 5.3. Let \( g : A \to S \) be an abelian scheme and let \( \sigma \) be a section of \( g \) such that for all \( s \in S(k) \), \( \sigma(s) \) is torsion of order prime to \( p \). Then \( \sigma \) is torsion of order prime to \( p \).

Proof. We may assume that \( S \) is normal and affine. Let us choose a subfield \( k' \subset k \) that is finitely generated and transcendental over \( F_p \), and such that \( A \to S \) and \( \sigma \) come by base change \( \text{Spec} k \to \text{Spec} k' \) from an abelian scheme \( g' : A' \to S' \) and a section \( \sigma' \) defined over \( k' \). Let \( m > 1 \) be prime to \( p \) and let \( \Gamma \) be the subgroup \( A'(S') \cap [m]^{-1}(\mathbb{Z}, \sigma') \) of \( A'(S') \). Then \( \Gamma \) is a finitely generated group. Note that assumptions of Néron’s specialization theorem [Chapter 9, Theorem 6.2] are satisfied and therefore there exists a Hilbert subset \( \Sigma \) of points \( s' \in S' \) for which the specialization map \( \mathcal{A}'(S') \to \mathcal{A}'_s(k(s')) \) is injective on \( \Gamma \). Since the Hilbert subset \( \Sigma \subset S' \) contains infinitely many closed points (see [Chapter 9, Theorems 5.1, 5.2 and 4.2]), there is a closed point \( s \in S \) the image of which in \( S' \) lies in \( \Sigma \). The specialization of \( \mathbb{Z}, \sigma \) at \( s \) is injective and hence \( \sigma \) is torsion of order dividing the order of \( \sigma(s) \), which is prime to \( p \).

Let us first assume that \( X \to S \) is of relative dimension 1. By passing to a finite cover of \( S \) we can assume that \( f \) has a section. The relative Picard scheme \( A = \text{Pic}^0(X/S) \to S \) is smooth. Using the above lemma to the section corresponding to the line bundle \( L \) we see that there exists some positive integer \( n \) prime to \( p \) and a line bundle \( M \) on \( S \) such that \( L^{\otimes n} \cong f^* M \). In particular, \( L^{\otimes n}_\eta \cong \mathcal{O}_{X_\eta} \).
Let us keep the notation from the beginning of the section, i.e., we see that the map $p$ closed field of positive characteristic $k$ of $X$. Therefore the family $(L^n_{\eta})_{n\in\mathbb{Z}}$ is bounded. Thus for any sufficiently ample divisor $H$ on $X_{\eta}$ we have $H^1(X_{\eta}, L^n_{\eta}(\eta)) = 0$ for all integers $n$. We consider such an $H$ which is defined over $\eta$.

Using Bertini’s theorem we can find a very ample divisor $Y \subset X$ in the linear system $|H|$ such that $f|_Y : Y \rightarrow S$ is smooth (possibly after shrinking $S$) and such that for every positive integer $n$ we have $H^1(X_{\eta}, L^{\otimes n}(-Y)|_{\eta}) = 0$. Indeed, shrinking $S$ and using semicontinuity of cohomology, we may assume that $H$ is defined over $S$, that the function $\dim H^0(X_{s}, \mathcal{O}_{X_{s}}(H))$ is constant and $S$ is affine. Let us choose a $k$-rational point $s$ in $S$. Then by Grauert’s theorem (see [Ha, Chapter III, Corollary 12.9]) the restriction map

$$H^0(X_{s}, \mathcal{O}_{X_{s}}(H)) \rightarrow H^0(X_{s}, \mathcal{O}_{X_{s}}(H))$$

is surjective. By Bertini’s theorem in the linear system $|\mathcal{O}_{X_{s}}(H)|$ there exists a smooth divisor. By the above we can lift it to a divisor $Y \subset X$, which after shrinking $S$ is the required divisor.

Applying our induction assumption to $L|_Y$ on $Y \rightarrow X$ we see that there exists a positive integer $n$ prime to $p$ such that $(L|_Y)^{\otimes n}_{\eta} = \mathcal{O}_{Y_{\eta}}$. Using the short exact sequence

$$0 \rightarrow L^{\otimes n}_{\eta}(-Y_{\eta}) \rightarrow L^{\otimes n}_{\eta} \rightarrow (L^{\otimes n}_{Y_{\eta}})_{\eta} \rightarrow 0$$

we see that the map

$$H^0(X_{\eta}, L^{\otimes n}_{\eta}) \rightarrow H^0(Y_{\eta}, (L^{\otimes n}_{Y_{\eta}})_{\eta})$$

is surjective. In particular, $L^{\otimes n}_{\eta}$ has a section and hence it is trivial.

Remarks 5.4. 1. Laszlo’s example shows that the first part of the theorem is false if one does not assume that orders of the monodromy groups of $E_s$ are prime to $p$ (in this example $E_{\eta}$ is a stable rank 2 vector bundle). Note that in this example, $E$ has even the richer structure of a relatively stratified bundle (see Proposition 1.3).

2. Let $E$ be a supersingular elliptic curve defined over $k = \overline{\mathbb{F}}_p$. Let $M$ be a line bundle of degree 0 and of infinite order on $E_{\overline{\mathbb{F}}_p(\ell)}$. Then one can find a smooth curve $S$ defined over $k$ such that there exists a line bundle $L$ on $X = S \times_k E \rightarrow S$ such that $L_{\eta} \simeq M$. In this example the line bundle $L_s$ is torsion for every $k$-rational point $s$ of $S$ as it is defined over a finite field. Since $E$ is a supersingular elliptic curve, there are no torsion line bundles of order divisible by $p$. In this case all line bundles $L_s$ for $s \in S(k)$ are étale trivializable (and the monodromy group has order prime to $p$).

This shows that the second part of Theorem 5.1 is no longer true if $k$ is an algebraic closure of a finite field.

Let us keep the notation from the beginning of the section, i.e., $k$ is an algebraically closed field of positive characteristic $p$ and $f : X \rightarrow S$ is a smooth projective morphism of $k$-varieties (in particular connected) with geometrically connected fibers. For simplicity, we also assume that $f$ has a section $\sigma : S \rightarrow X$. 

Documenta Mathematica 18 (2013) 23–50
Lemma 5.5. Let $E$ be a locally free sheaf on $X$. If there exists a point $s_0 \in S(k)$ such that $E_{s_0}$ is numerically flat then $E_\eta$ is also numerically flat. In particular, if there exists a point $s_0 \in S(k)$ such that there is a finite covering $\pi_{s_0} : X_{s_0} \to X_0$ such that $\pi_{s_0}^*(E_{s_0})$ is trivial, then $E_\eta$ is also numerically flat.

Proof. Let us fix a relatively ample line bundle. If $E_{s_0}$ is numerically flat then it is strongly semistable with numerically trivial Chern classes (see [La2, Proposition 5.1]). Since $E$ is $S$-flat, the restriction of $E$ to any fiber has numerically trivial Chern classes (as intersection numbers remain constant on fibers). Now note that for any $n$ the sheaf $(F^n_{X_0/k})^*E_{s_0}$ is slope semistable. Since slope semistability is an open property, it follows that $(F^n_{X_0/k})^*E_\eta$ is also slope semistable. By [HL, Corollary 1.3.8] it follows that $(F^n_{X_0/k})^*E_\eta$ is also slope semistable. Thus $E_\eta$ is strongly semistable with vanishing Chern classes and hence it is numerically flat by [La2, Proposition 5.1].

Let us recall that numerically flat sheaves on a proper $k$-variety $Y$ form a Tannakian category. A rational point $y \in Y(k)$ neutralizes it. Thus we can define $S$-fundamental group scheme of $Y$ at the point $y$ (see [La2, Definition 6.1]). For a numerically flat sheaf $E$ on $Y$, we consider the Tannaka $k$-group $\pi_S((E), y) := Aut^\otimes((E), y) \subset GL(E_y)$, where now $(E)$ is the full tensor subcategory of numerically flat bundles spanned by $E$. We call it the $S$-monodromy group scheme. Using this language we can reformulate Theorem 5.5 in the following way (for simplicity we reformulate only the second part of the theorem).

Theorem 5.6. Let $E$ be an $S$-flat family of numerically flat sheaves on the fibers of $X \to S$. Let us assume that $k$ is not algebraic over its prime field and there exists a non-empty open subset $U \subset S(k)$ such that for every $s \in U$, the $S$-monodromy group scheme $\pi_S((E_s), \sigma(s))$ is finite étale of order prime-to-$p$. Then $\pi_S((E_\eta), \sigma(\eta))$ is also finite étale.

6 Verschiebung divisible points on abelian varieties: on the theorem by M. Raynaud

Let $K$ be an arbitrary field of positive characteristic $p$ and let $A$ be an abelian variety defined over $K$. The multiplication by $p^n$ map $[p^n] : A \to A$ factors through the relative Frobenius morphism $F_{A/K}^n : A \to A^{(n)}$ and hence defines the Verschiebung morphism $V^n : A^{(n)} \to A$ such that $V^n F_{A/K}^n = [p^n]$.

Definition 6.1. A $K$-point $P$ of $A$ is said to be $V$-divisible if for every positive integer $n$ there exists a $K$-point $P_n$ in $A^{(n)}$ such that $V^n(P_n) = P$.

Let $T$ be an integral noetherian separated scheme of dimension 1 with field of rational functions $K$. Let us recall that a smooth, separated group scheme of finite type $\mathcal{G} \to T$ is called a Néron model of $A$ if the general fiber of $\mathcal{G} \to T$ is isomorphic to $A$ and for every smooth morphism $X \to T$, a morphism $X_K \to \mathcal{G}_K$ extends (then uniquely) to a $T$-morphism $X \to \mathcal{G}$.
Assume that the base field $K$ is the function field of a normal projective variety $S$ defined over a field $k$ of positive characteristic $p$.

We say that $A$ has a good reduction at a codimension 1 point $s \in S$ if the Néron model of $A$ over $\text{Spec} \mathcal{O}_{S,s}$ is an abelian scheme (the usual definition is slightly different as it assumes that the identity component of the special fibre of the Néron model is an abelian variety; it is equivalent to the above one by [BLR, 7.4, Theorem 5]). We say that $A$ has potential good reduction at a codimension 1 point $s \in S$ if there exists a finite Galois extension $K'$ over $K$ such that if $S'$ is the normalization of $S$ in $K'$ then $A_{K'}$ has good reduction at every codimension 1 point $s' \in S'$ lying over $s$.

We say that $A$ has (potential) good reduction if it has (potential) good reduction at every codimension 1 point of $S$. Assume that $A$ has good reduction at every codimension 1 point of $S$. Then there exists a big open subset $U \subset S$ (i.e., the codimension of the complement of $U$ in $S$ is $\geq 2$) and an abelian $U$-scheme $\mathfrak{A} \to U$. Note that the group $A(K)$ of $K$-points of $A$ is isomorphic via the restriction map to the group of rational sections $U \dashrightarrow \mathfrak{A}$ of $\mathfrak{A} \to U$ defined over some big open subset of $U$. The section corresponding to $P \in A(K)$ will be denoted by $\hat{P}: U \dashrightarrow \mathfrak{A}$.

Let $c \in \text{Pic} A$ be a class of a line bundle $L$. By the theorem of the cube $c$, satisfies the following equality:

$$m_1^{12}c - m_1^{12}c - m_2^{12}c + m_1^c + m_2^c + m_3^c = 0,$$

where $m_I$ for $I \subset \{1,2,3\}$ is the map $A \times_K A \times_K A \to A$ defined by addition over the factors in $I$. (In particular, $m_i$ is the $i$-th projection). Combining [MB, Chapter III, 3.1] (relying on the Proposition 1.2.1), the line bundle $L \in \text{Pic}(A)$ extends uniquely (at least if we fix a rigidification) to a line bundle $\hat{L}$ over $\mathfrak{A}$ such that the class $\hat{c} = [\hat{L}] \in \text{Pic}(\mathfrak{A})$ is cubical, i.e., satisfies the relation

$$\hat{m}_1^{12}\hat{c} - \hat{m}_1^{12}\hat{c} - \hat{m}_2^{12}\hat{c} + \hat{m}_1^c + \hat{m}_2^c + \hat{m}_3^c = 0,$$

where $V \subset U$ is a big open subset and where $\hat{m}_I$ for $I \subset \{1,2,3\}$ is the map $\mathfrak{A} \times_S \mathfrak{A} \times_S \mathfrak{A} \to \mathfrak{A}$ defined by addition over the factors in $I$.

Now let us choose an ample line bundle $H$ on $S$. Then the map $\hat{h}_c: A(K) \to \mathbb{Z}$ given by

$$\hat{h}_c(P) = \text{deg}_H(\hat{P} - \hat{0})^*\hat{c}$$

is well defined as $\hat{P}$ is defined on a big open subset of $S$ and $\hat{P}^*\hat{L}$ extends to a rank 1 reflexive sheaf on $S$. This map is the canonical (Néron–Tate) height of $A$ corresponding to $c$ (see [MB, Chapter III, Section 3]).

The following theorem was suggested to the authors by M. Raynaud (in the good reduction case over a curve $S$, and with a somewhat different proof).

**Theorem 6.2.** Assume that $A$ has potential good reduction. If $P \in A(K)$ is $V$-divisible and $c$ is symmetric then $\hat{h}_c(P) = 0$.

**Proof.** Let us first assume that $A$ has good reduction. By assumption there exists a $K$-point $P_n$ of $A^{(n)}$ such that $V^n(P_n) = P$. Since $\mathfrak{A} \to U$ is an abelian scheme, so is $\mathfrak{A}^{(n)} \to U$, thus $P_n$ is the restriction to $\text{Spec} K$ of $\hat{P}_n \in \mathfrak{A}^{(n)}(U)$. 

Let us factor the absolute Frobenius morphism $F^n_A$ into the composition of the relative Frobenius morphism $F^n_{A/K} : A \to A^{(n)}$ and $W_n : A^{(n)} \to A$. Let us set $c_n = W^n_n c$. Its cubical extension $\tilde{c}_n \in \text{Pic}(\omega^{(n)}_A)$, for some big open $V_n \subset U$, together with $H$ allows one to define $\tilde{h}_{c_n}(P_n)$ by the corresponding formula. Since $(F^n_A)^*c = p^n c$, we have $(F^n_{A/K})^*c_n = p^n c$. On the other hand, since $c$ is symmetric, we have $[p^n]^*c = p^{2n}c$ and hence $(F^n_{A/K})^*((V^n)^*c) = p^{2n}c$. Therefore

$$(F^n_{A/K})^*((V^n)^*c - p^n c_n) = 0.$$  

Since $F^n_{A/K}$ is an isogeny this implies that the class $d = (V^n)^*c - p^n c_n$ is torsion. By additivity and functoriality of the canonical height (see [Se, Theorem, p. 35]) we have

$$\tilde{h}_c(P) = \tilde{h}_{(V^n)^*c}(P_n) = \tilde{h}_{p^n c_n}(P_n) + \tilde{h}_d(P_n) = p^n \cdot \tilde{h}_{c_n}(P_n)$$

(note that additivity implies that $\tilde{h}_{md} = m\tilde{h}_d$, so since $md = 0$ for some $m$, we get $\tilde{h}_d = 0$). Therefore if $\tilde{h}_c(P) \neq 0$ then $|\tilde{h}_c(P)| \geq p^n$ and we get a contradiction if $n$ is sufficiently large.

Now let us consider the general case. Since there exist only finitely many codimension 1 points $s \in S$ at which $A$ has bad reduction, one can find a finite Galois extension $K'$ of $K$ such that if $S'$ is the normalization of $S$ in $K'$ then $A_{K'}$ has good reduction at every codimension 1 point $s' \in S'$. On the other hand, if $P \in A(K)$ is $V$-divisible on $A$, $P \otimes K' \subset A(K')$ is $V$ divisible on $A_{K'}$. Then by the above we have $h_{V^n}(P') = 0$ and functoriality of the canonical height implies that $\tilde{h}_c(P) = 0$.

**Remark 6.3.** It is an interesting problem whether Theorem 6.2 holds for an arbitrary abelian variety $A/K$. Its proof shows that one can use the semiabelian reduction theorem to reduce the general statement to the case when $A$ has semiabelian reduction (see [BLR, 7.4, Theorem 1]).

Now assume that $S$ is geometrically connected. Then the extension $k \subset K$ is regular (i.e., $K/k$ is separable and $k$ is algebraically closed in $K$). Let $(B, \tau)$ be the $K/k$-trace of the abelian $K$-variety $A$, where $B$ is an abelian $k$-variety and $\tau : B_k \to A$ is a homomorphism of abelian $K$-varieties (it exists by [Co] Theorem 6.2). Let us recall that by definition $(B, \tau)$ is a final object in the category of pairs consisting of an abelian $k$-variety and a $K$-map from the scalar $K$-extension of this variety to $A$.

Since the extension $k \subset K$ is regular, the kernel $K$-group scheme of $\tau$ is connected (with connected dual) ([Co] Theorem 6.12). Therefore $\tau$ is injective on $K$-points and in particular we can treat $B(k)$ as a subgroup of $A(K)$.

**Corollary 6.4.** Assume that $A$ has potential good reduction. If $P \in A(K)$ is $V$-divisible then $[P] \in (A(K)/B(k))_{\text{tors}}$. In particular, if $k$ is algebraically closed then $P \in B(k) + A(K)_{\text{tors}} \subset A(K)$.

**Proof.** We can choose the class $c \in \text{Pic}(A)$ so that it is ample and symmetric. Then the first part of the corollary follows from Theorem 6.2 and [Co, Theorem 9.15] (which is true for regular extensions $K/k$).
In this section we use the height estimate of the previous section and the fact that torsion stratified line bundles on a perfect field have order prime to $p$ (apply Proposition \ref{prop:height-estimation} together with Lemma \ref{lem:height-bound}).

7 Stratified bundles

To prove the second part take positive integer $m$ such that $mP = Q \in B(k)$. Since $k$ is algebraically closed, the set $B(k)$ is divisible and there exists $Q' \in B(k)$ such that $mQ' = Q$. Then $P = Q' + (P - Q')$, where $m(P - Q') = 0$.

Let us assume that the field $k$ is algebraically closed. It is an interesting question whether a $V$-divisible $K$-point $P$ of $A$ can be written as a sum of $Q + R$, where $Q \in B(k)$ and $R \in A(K)_{\text{tors}}$ is torsion of order prime-to-$p$.

By the Lang–Néron theorem (\cite[Theorem 2.1]{Co}), the groups $A^{(i)}(K)/B^{(i)}(k)$ are finitely generated. It follows that the groups $G_i = (A^{(i)}(K)/B^{(i)}(k))_{\text{tors}}$ are finite.

Note that the homomorphism $B(k) \to B^{(i)}(k)$ induced by $F_{i/k}$ is a bijection. One has a factorization $F_{i/k} : A(K^{1/p^i}) \to A^{(i)}(K) \to A^{(i)}(K^{1/p^i})$, inducing a bijection $A(K^{1/p^i}) \to A^{(i)}(K)$. Thus in particular,

$$F_i : A(K)/B(k) \to A^{(i)}(K)/B^{(i)}(k)$$

is injective.

Moreover, the Verschiebung morphism induces the homomorphisms

$$V_i : A^{(i)}(K)/B^{(i)}(k) \to A(K)/B(k)$$

such that $V_i F_i = p^i$ and $F_i V_i = p^i$. This shows that prime-to-$p$ torsion subgroups of groups $G_i$ are isomorphic and in particular have the same order $m$.

Now let us assume that orders of the $p$-primary torsion subgroups of the abelian groups $G_i$ are uniformly bounded by some $p^e$. Then for all $i \geq e$

$$F_i([mP]) = F_i(V_i([mP_0])) = p^i m P_0 = 0.$$  

This implies that $mP_0 = 0$, so $mP \in B(k)$. Now $B(k)$ is a divisible group so there exists some $Q' \in B(k)$ such that $mQ' = mQ$. Then $R = P - Q \in A(K)$ is torsion of order prime to $p$. So we conclude

\textbf{Lemma 6.5.} \textit{If the order of the $G_i$ is bounded as $i$ goes to infinity, under the assumption the Theorem \ref{prop:height-estimation} there exists a positive integer $m$, prime to $p$ and such that $m \cdot P_i \in B(k)$ for every integer $i$.}

Note that the above assumption on $G_i$ is satisfied, e.g., if $A$ is an elliptic curve over the function field $K$ of a smooth curve over $k = \overline{k}$. If $A$ is isotrivial then the assertion is clear. If $A$ is not isotrivial then the $j$-invariant of $A$ is transcendental over $k$. In this case $A(K^{1/p^i})_{\text{tors}}$ is finite (see \cite{Le}) so orders of the groups $G_i = A^{(i)}(K)_{\text{tors}}$ are uniformly bounded.

Documenta Mathematica 18 (2013) 23–50
Let \( k \) be an algebraically closed field of positive characteristic \( p \). Let \( f : X \to S \) be a smooth projective morphism of \( k \)-varieties with geometrically connected fibres. Assume that \( S \) is projective, which surely is a very strong assumption. Indeed, if \( k \neq \mathbb{F}_p \), and in the statement of Theorem 7.1 \( S' \) is open, then one obtains the stronger Theorem 7.2. For simplicity, let us also assume that \( f \) has a section \( \sigma : S \to X \).

Consider the torsion component \( \text{Pic}^\tau(X/S) \to \text{Pic}(X/S) \) of identity of \( \text{Pic}(X/S) \to S \). Let \( \phi_n : \text{Pic}(X/S) \to \text{Pic}(X/S) \) be the multiplication by \( n \) map. Then there exists an open subgroup scheme \( \text{Pic}^\tau(X/S) \) of \( \text{Pic}(X/S) \) such that every geometric point \( s \) of \( S \) the fibre of \( \text{Pic}^\tau(X/S) \) over \( s \) is the union

\[
\bigcup_{n > 0} \phi_n^{-1}(\text{Pic}^0(X_i)),
\]

where \( \text{Pic}^0(X_i) \) is the connected component of the identity of \( \text{Pic}(X_i/s) \). It is well known that \( \text{Pic}^\tau(X/S) \to S \) is also a closed subgroup scheme of \( \text{Pic}(X/S) \). Moreover, the morphism \( \text{Pic}^\tau(X/S) \to \text{Pic}(X/S) \) is projective and the formation of \( \text{Pic}^\tau(X/S) \to S \) commutes with a base change of \( S \) (see, e.g., [K], Theorem 6.16 and Exercise 6.18). We assume that \( \text{Pic}^0(X_i) \) is reduced for every point \( s \in S \).

**Theorem 7.1.** Let \( L = \{L_i, \sigma_i\} \) be a relatively stratified line bundle on \( X/S \). Assume that there exists a dense subset \( S' \subset S(k) \) such that for every \( s \in S', \) the stratified bundle \( L_s = L_s|_{X_s} \) has finite monodromy. Then \( L_{\eta} \) has finite monodromy.

**Proof.** Replacing \( L \) by a power \( L \otimes N \), where \( N \) is sufficiently large, we may assume that \( L_{\eta} \in \text{Pic}^0(X_i) \) for all closed points \( s \) in \( S \) (see [K], Corollary 6.17)). By assumption \( \tilde{\pi} : \mathcal{A} = \text{Pic}^0(X/S) \to S \) is an abelian scheme. Let us consider the dual abelian scheme \( \mathcal{A}' \to S \). We have a well defined Albanese morphism \( g : (X, \sigma) \to (\mathcal{A}', e) \) (see [FGA], Exposé VI, Théorème 3.3)). Moreover, the map \( g^*: \text{Pic}^0(\mathcal{A}/S) \to \mathcal{A}' = \text{Pic}^0(X/S) \) is an isomorphism of \( S \)-schemes. Let us set \( \hat{A} = \mathcal{A}'_{\eta} \).

Let \( P_i \) be the \( K \)-point of \( \hat{A}^{(i)} \) corresponding to \((L_i)_{\eta}\). Note that the \( K \)-point \( P_0 \in \hat{A} \) is \( V \)-divisible. Indeed, by the definition of a relative stratification we have \( V^P(P_0) = P_0 \) for all integers \( n \). Similarly, we see that all the points \( P_i \in \hat{A}^{(i)}(K) \) are \( V \)-divisible. By Corollary 6.4 it follows that \( P_i \in \hat{B}^{(i)}(k) + \hat{A}^{(i)}(K)_{\text{crys}} \), where \( \hat{B}/k, \tilde{\pi} : \hat{B} \to \hat{A} \) is the \( K/k \)-trace of \( \hat{A} \) (note that \( \hat{B}^{(i)}/k, \tilde{\pi}^{(i)} \) is the \( K/k \)-trace of \( \hat{A}^{(i)} \)). So for every \( i \geq 0 \) we can write \( P_i = Q_i + R_i \) for some \( Q_i \in \hat{B}^{(i)}(k) \) and \( R_i \in \hat{A}^{(i)}(K)_{\text{crys}} \).

Now we transpose the above by duality. Let \( A \) be the dual abelian \( K \)-variety of \( \hat{A} \) and \( B \) the dual abelian \( k \)-variety of \( \hat{B} \). We have the \( K/k \)-images \( \tau^{(i)} : A^{(i)}_{\eta} \to B^{(i)}_k \) and an \( S \)-morphism \( \tau : \mathcal{A} \to B \times_k S \) (possibly after shrinking \( S \)). By abuse of notation we can treat \( L_i \) as line bundles on \( \mathcal{A} \) because \( g^*: \text{Pic}^0(\mathcal{A}/S) \to \text{Pic}^0(X/S) \) is an isomorphism. Let \( M_i \) be the line bundle on \( B^{(i)} \) corresponding to \( Q_i \) and let \( \pi_i : B^{(i)} \times_k S \to B^{(i)} \) denote the projection. Let us fix a non-negative integer \( i \) and take a positive integer \( n_i \), such that \( n_i R_i = 0 \). Then the line bundle \( L^{(i)n_i} \otimes \tau^* \pi_i^* M^{(i)n_i} \) has degree 0 on every fiber of \( \mathcal{A} \to S \). Thus it is trivial after restriction to \( \mathcal{A}_{\eta} \). Hence after shrinking \( S \) we can assume that \( L^{(i)n_i} \simeq \tau^* \pi_i^* M^{(i)n_i} \).

Let us fix a point \( s \in S(k) \) and consider the morphism

\[
\pi_i' = (\tau^{(i)} \pi_i)_{\mathcal{A}^{(i)}_{\eta}} : \mathcal{A}^{(i)}_{\eta} \to B^{(i)}.
\]
Note that $\tau^{(i)}$ has connected fibres and hence $(\pi')_i^*\mathcal{O}_{\mathcal{X}^{(i)}} = \mathcal{O}_{\mathcal{Y}^{(i)}}$. By assumption there exists a positive integer $a_i$, such that for every $i$ the order of the line bundle $(L_i)_s$ divides $a_i$. The important point is that $a_i$ is prime to $p$.

Therefore $(\pi')_1^*M_i^{[a_i]} \simeq \mathcal{O}_{A_i}$ and by the projection formula

$$M_i^{[a_i]} \simeq (\pi')_1^* \mathfrak{M}_i^{[a_i]} \simeq (\pi')_1^* \mathcal{O}_{A_i} \simeq \mathcal{O}_B.$$ 

This implies that $M_i$ is a torsion line bundle and hence $Q_i \in \mathcal{A}^{(i)}(K)_{\text{tors}}$. Therefore

$$P_i = Q_i + R_i \in \mathcal{A}^{(i)}(K)_{\text{tors}}.$$ 

Let us recall that the set of $p$-torsion points of $\mathcal{A}(K)$ is finite. Assuming it is not empty, we can therefore find a non-empty open subset $U \subset S$ such that for every $s \in U(k)$ and every $p$-torsion point $\mathfrak{T} \in \mathcal{A}(K)$ the section $\mathfrak{T}$ is defined on $U$ and the point $\mathfrak{T}(s)$ is non-zero.

Let us write the order of $P_i$ as $m_i p^{e_i}$, where $m_i$ is not divisible by $p$. If $e_0 \geq 1$ then the point $m_0 p^{e_0 - 1} P_0$ is $p$-torsion in $\mathcal{A}(K)$. If we take $s \in S \cap U(k)$, then $a_i m_i p^{e_i - 1} P_0(s) = [L_i^{[a_i]}]_{\mathfrak{X}_0} = 0$, a contradiction. It follows that $m_0 P_0 = 0$. Similarly, the order of all $P_i$ is prime to $p$.

As already mentioned in the last section, the homomorphism $\mathcal{A}(K^{1/p}) \to \mathcal{A}^{(i)}(K)$ induced by $F_i^{1/p}_{A/K}$ is a bijection. So we have an induced injection

$$F_i: \mathcal{A}(K) \to \mathcal{A}^{(i)}(K).$$ 

On the other hand, the Verschiebung morphism induces homomorphisms

$$V_i: \mathcal{A}^{(i)}(K) \to \mathcal{A}(K)$$

such that $V_i F_i(P) = p^i P$ and $F_i V_i(Q) = p^i Q$ for all $P \in \mathcal{A}(K)$ and $Q \in \mathcal{A}^{(i)}(K)$. Hence

$$p^i m_i P_i = F_i V_i(m_i P_i) = F_i(m_i P_0) = 0$$

and since the order of $P_i$ is prime to $p$ we have $m_0 P_i = 0$ for all $i \geq 0$. Therefore $(L_i)^{[m_0]} \simeq \mathcal{O}_{\mathfrak{X}_0}$ for all $i$ and the stratified line bundle $\mathcal{L}_\eta$ has finite monodromy.

Now we fix the following notation: $k$ is an algebraically closed field of positive characteristic $p$ and $f: X \to S$ is a smooth projective morphism of $k$-varieties with geometrically connected fibres.

**Theorem 7.2.** Let $\mathcal{E} = \{E_i, \sigma_i\}$ be a relatively stratified bundle on $X/S$. Assume that there exists a dense subset $U \subset S(k)$ such that for every $s \in U$ the stratified bundle $\mathcal{E}_s = \mathcal{E}|_X$, has finite monodromy of order prime to $p$.

1) Then there exists a finite Galois étale covering $\pi_\mathfrak{q}: \mathcal{Y}_\mathfrak{q} \to \mathcal{X}_\mathfrak{q}$ of order prime-to-$p$ such that $\pi_\mathfrak{q}^* \mathcal{E}_\mathfrak{q}$ is a direct sum of stratified line bundles.
2) If \( k \neq \bar{F} \) and \( U \) is open in \( S(k) \), then the monodromy group of \( \mathbb{E}_\eta \) is finite, and \( \mathbb{E}_\eta \) trivializes on a finite étale cover \( Z_\eta \rightarrow X_\eta \) which factors as a Kummer (thus finite abelian of order prime to \( p \)) cover \( Z_\eta \rightarrow Y_\eta \) and a Galois cover \( Y_\eta \rightarrow X_\eta \) of order prime to \( p \).

**Proof.** We prove 1). Let us first remark that the schemes \( X_{i \eta} \), \( i \geq 0 \), are all isomorphic (as schemes, not as \( k \)-schemes). Therefore the relative Frobenius induces an isomorphism on fundamental groups.

By the first part of Theorem 5.1 we know that there exists a finite Galois étale covering \( \pi_i: Y_{i \eta} \rightarrow X_{i \eta} \) of degree prime to \( p \) such that \( \pi_i^*(E_i) \) is a direct sum of line bundles \( \bigoplus_{j=1}^r L_{i j} \). Note that from the proof of Theorem 5.1 the degree of \( \pi_i \) depends only on \( \pi_{\sigma_i}^*(X_{i \eta}, \sigma_i^*(\bar{\eta})) \) and the Brauer-Feit constant \( j(r) \), and therefore it can be bounded independently of \( i \). Using the Lang–Serre theorem (see [LS, Théorème 4]) we can therefore assume that \( Y_{i \eta} = Y_{\eta} \), where \( Y_\eta = Y_{0 \eta} \). Now we know that

\[
\bigoplus_{j=1}^r L_{i j} \simeq (F_i^{j})^{*}(\bigoplus_{j'=1}^{r'} L_{i+1, j'}) .
\]

By the Krull-Schmidt theorem, the set of isomorphism classes of line bundles \( \{L_{i j}\}_j \) is the same as the set of isomorphism classes of lines bundles which come by pull-back \( \{(F_i^{j})^{*}(L_{i+1, j'})\}_j \). So we can reorder the indices \( j' \) so that

\[
(F_i^{j})^{*}(L_{i+1, j}) \simeq L_{i, j} .
\]

This finishes the proof of 1).

To prove 2), we do the proof 1) replacing \( Y_\eta \rightarrow X_\eta \) by \( Z_\eta \rightarrow X_\eta \) of Theorem 5.1 2). This finishes the proof of 2).

\[\square\]

**Remarks 7.3.**

1) Case 2) of Theorem 7.2 applied to a line bundle extends Theorem 7.1 where \( S \) was assumed to be projective, \( \text{Pic}^0(X_s) \) reduced for all \( s \in S \) closed, \( S' \subset S(k) \) dense, to the case when \( S \) is not necessarily projective and \( S' \subset S(k) \) is open and dense, but we have to assume that \( k \) is not algebraic over its prime field.

2) If \( Y_\eta \) has a good projective model satisfying assumptions of Theorem 7.1 then it follows that \( \mathbb{E}_\eta \) has finite monodromy.

BIRATIONAL MOTIVIC HOMOTOPY THEORIES
AND THE SLICE FILTRATION

PABLO PELAEZ

Received: May 21, 2012
Revised: October 5, 2012
Communicated by Lars Hesselholt

ABSTRACT. We show that there is an equivalence of categories between the orthogonal components for the slice filtration and the birational motivic stable homotopy categories which are constructed in this paper. Relying on this equivalence, we are able to describe the slices for projective spaces (including $\mathbb{P}^\infty$), Thom spaces and blow ups.

2000 Mathematics Subject Classification: 14F42
Keywords and Phrases: Birational Invariants, Motivic Homotopy Theory, Motivic Spectral Sequence, Slice Filtration.

1 Definitions and Notation

Our main result, theorem 3.6, shows that there is an equivalence of categories between the orthogonal components for the slice filtration (see definition 1.1) and the weakly birational motivic stable homotopy categories which are constructed in this paper (see definition 2.9). Relying on this equivalence; we are able to describe over an arbitrary base scheme (see theorems 4.2, 4.4 and 4.6) the slices for projective spaces (including $\mathbb{P}^\infty$), Thom spaces and blow ups. We also construct the birational motivic stable homotopy categories (see definition 2.4), which are a natural generalization of the weakly birational motivic stable homotopy categories, and show (see proposition 2.12) that there exists a Quillen equivalence between them when the base scheme is a perfect field. Our approach was inspired by the work of Kahn-Sujatha [1] on birational motives, where the existence of a connection between the layers of the slice filtration and birational invariants is explicitly suggested. Furthermore, this approach...
allows to obtain analogues for the slice filtration in the unstable setting (see remark 3.8).

In this paper, $X$ will denote a Noetherian separated base scheme of finite Krull dimension, $\text{Sch}_X$ the category of schemes of finite type over $X$ and $\text{Sm}_X$ the full subcategory of $\text{Sch}_X$ consisting of smooth schemes over $X$ regarded as a site with the Nisnevich topology. All the maps between schemes will be considered over the base $X$. Given $Y \in \text{Sch}_X$, all the closed subsets $Z$ of $Y$ will be considered as closed subschemes with the reduced structure.

Let $\mathcal{M}$ be the category of pointed simplicial presheaves in $\text{Sm}_X$ equipped with the motivic Quillen model structure [14] constructed by Morel-Voevodsky [8, p. 86 Thm. 3.2], taking the affine line $\mathbb{A}_X^1$ as interval. Given a map $f : Y \to W$ in $\text{Sm}_X$, we will abuse notation and denote by $f$ the induced map $f : Y_+ \to W_+$ in $\mathcal{M}$ between the corresponding pointed simplicial presheaves represented by $Y$ and $W$ respectively.

We define $T$ in $\mathcal{M}$ to be the pointed simplicial presheaf represented by $S^1 \wedge \mathbb{G}_m$, where $\mathbb{G}_m$ is the multiplicative group $\mathbb{A}_X^1 - \{0\}$ pointed by 1, and $S^1$ denotes the simplicial circle. Given an arbitrary integer $r \geq 1$, $S^r$ (respectively $\mathbb{G}_m^r$) will denote the iterated smash product $S^1 \wedge \cdots \wedge S^1$ (respectively $\mathbb{G}_m^r$) with $r$-factors; $S^0 = \mathbb{G}_m^0$ will be by definition equal to the pointed simplicial presheaf $X_+$ represented by the base scheme $X$.

Let $\text{Spt}(\mathcal{M})$ denote Jardine’s category of symmetric $T$-spectra on $\mathcal{M}$ equipped with the motivic model structure defined in [6, Thm. 4.15] and let $\mathcal{SH}$ denote its homotopy category, which is triangulated. We will follow Jardine’s notation [6, p. 506-507] where $F_n$ denotes the left adjoint to the $n$-evaluation functor

$$
\text{Spt}(\mathcal{M}) \xrightarrow{ev_n} \mathcal{M} \\
(X^m)_{m \geq 0} \xrightarrow{X^n} \mathcal{M}
$$

Notice that $F_0(A)$ is just the usual infinite suspension spectrum $\Sigma^\infty A$.

For every integer $q \in \mathbb{Z}$, we consider the following family of symmetric $T$-spectra

$$
C^q_{\text{eff}} = \{ F_n(S^r \wedge \mathbb{G}_m^s \wedge U_+) \mid n, r, s \geq 0; s - n \geq q; U \in \text{Sm}_X \} \tag{1.1}
$$

where $U_+$ denotes the simplicial presheaf represented by $U$ with a disjoint base point.

Let $\Sigma^q_\mathcal{SH}^{\text{eff}}$ denote the smallest full triangulated subcategory of $\mathcal{SH}$ which contains $C^q_{\text{eff}}$ and is closed under arbitrary coproducts. Voevodsky [16] defines the slice filtration in $\mathcal{SH}$ to be the following family of triangulated subcategories

$$
\cdots \subseteq \Sigma^{q+1}_\mathcal{SH}^{\text{eff}} \subseteq \Sigma^q_\mathcal{SH}^{\text{eff}} \subseteq \Sigma^{q-1}_\mathcal{SH}^{\text{eff}} \subseteq \cdots
$$

It follows from the work of Neeman [9], [10] that the inclusion

$$
i_q : \Sigma^q_\mathcal{SH}^{\text{eff}} \to \mathcal{SH}$$

Documenta Mathematica 18 (2013) 51–70
Birational Motivic Homotopy Theories

has a right adjoint \( r_q : \mathcal{SH} \rightarrow \Sigma_q^T \mathcal{SH}^{eff} \), and that the following functors

\[
\begin{align*}
    f_q &: \mathcal{SH} \rightarrow \mathcal{SH} \\
    s_{<q} &: \mathcal{SH} \rightarrow \mathcal{SH} \\
    s_q &: \mathcal{SH} \rightarrow \mathcal{SH}
\end{align*}
\]

are triangulated, where \( f_q \) is defined as the composition \( i_q \circ r_q \); and \( s_{<q}, s_q \) are characterized by the fact that for every \( E \in \mathcal{SH} \), we have distinguished triangles in \( \mathcal{SH} \):

\[
\begin{align*}
    f_q E \to^\theta E \to s_{<q} E \to S^1 \wedge f_q E \\
    f_{q+1} E \to^\theta f_q E \to s_q E \to S^1 \wedge f_{q+1} E
\end{align*}
\]

We will refer to \( f_q E \) as the \((q - 1)\)-connective cover of \( E \), to \( s_{<q} E \) as the \( q \)-orthogonal component of \( E \), and to \( s_q E \) as the \( q \)-slice of \( E \). It follows directly from the definition that \( s_{<q+1} E, s_q E \) satisfy that for every symmetric \( T \)-spectrum \( K \) in \( \Sigma_{q+1}^T \mathcal{SH}^{eff} \):

\[
\text{Hom}_{\mathcal{SH}}(K, s_{<q+1} E) = \text{Hom}_{\mathcal{SH}}(K, s_q E) = 0
\]

**Definition 1.1.** Let \( E \in Spt(\mathcal{M}) \) be a symmetric \( T \)-spectrum. We will say that \( E \) is \( n \)-orthogonal, if for all \( K \in \Sigma_n^T \mathcal{SH}^{eff} \)

\[
\text{Hom}_{\mathcal{SH}}(K, E) = 0
\]

Let \( \mathcal{SH}^{\perp}(n) \) denote the full subcategory of \( \mathcal{SH} \) consisting of the \( n \)-orthogonal objects.

The slice filtration admits an alternative definition in terms of (left and right) Bousfield localization of \( Spt(\mathcal{M}) \) [11, 12]. The Bousfield localizations are constructed following Hirschhorn’s approach [2]. In order to be able to apply Hirschhorn’s techniques, it is necessary to know that \( Spt(\mathcal{M}) \) is cellular [2, Def. 12.1.1] and proper [2, Def. 13.1.1].

**Theorem 1.2.** The Quillen model category \( Spt(\mathcal{M}) \) is:

1. cellular (see [5], [3, Cor. 1.6] or [12, Thm. 2.7.4]).
2. proper (see [6, Thm. 4.15]).

For details and definitions about Bousfield localization we refer the reader to Hirschhorn’s book [2]. Let us just mention the following theorem of Hirschhorn, which guarantees the existence of left and right Bousfield localizations.
Let $A$ be a Quillen model category which is cellular and proper. Let $L$ be a set of maps in $A$ and let $K$ be a set of objects in $A$. Then:

1. The left Bousfield localization of $A$ with respect to $L$ exists.
2. The right Bousfield localization of $A$ with respect to the class of $K$-colocal equivalences exists.

Now, we can describe the slice filtration in terms of suitable Bousfield localizations of $Spt(M)$.

**Theorem 1.4** (see [12]). 1. Let $R_{C_{q}^{\text{eff}}}Spt(M)$ be the right Bousfield localization of $Spt(M)$ with respect to the set of objects $C_{q}^{\text{eff}}$ (see Eqn. (1.1)). Then its homotopy category $R_{C_{q}^{\text{eff}}}S_{q}H$ is triangulated and naturally equivalent to $\Sigma_{q}S_{q}H^{\text{eff}}$. Moreover, the functor $f_{q}$ is canonically isomorphic to the following composition of triangulated functors:

$$S_{q}H \xrightarrow{R} R_{C_{q}^{\text{eff}}}S_{q}H \xrightarrow{C_{q}} S_{q}H$$

where $R$ is a fibrant replacement functor in $Spt(M)$, and $C_{q}$ a cofibrant replacement functor in $R_{C_{q}^{\text{eff}}}Spt(M)$.

2. Let $L_{<q}Spt(M)$ be the left Bousfield localization of $Spt(M)$ with respect to the set of maps

$$\{ F_{n}(S^{r} \wedge G_{m}^{s} \wedge U_{+}) \to * \mid F_{n}(S^{r} \wedge G_{m}^{s} \wedge U_{+}) \in C_{q}^{\text{eff}} \}$$

Then its homotopy category $L_{<q}S_{q}H$ is triangulated and naturally equivalent to $S_{q}H^{\perp}(q)$. Moreover, the functor $s_{<q}$ is canonically isomorphic to the following composition of triangulated functors:

$$S_{q}H \xrightarrow{Q} L_{<q}S_{q}H \xrightarrow{W_{q}} S_{q}H$$

where $Q$ is a cofibrant replacement functor in $Spt(M)$, and $W_{q}$ a fibrant replacement functor in $L_{<q}Spt(M)$.

3. Let $S^qSpt(M)$ be the right Bousfield localization of $L_{<q+1}Spt(M)$ with respect to the set of objects

$$\{ F_{n}(S^{r} \wedge G_{m}^{s} \wedge U_{+}) \mid n, r, s \geq 0; s - n = q; U \in Sm_{X} \}$$

Then its homotopy category $S^qS_{q}H$ is triangulated and the identity functor $id : R_{C_{q}^{\text{eff}}}Spt(M) \to S^qSpt(M)$

is a left Quillen functor. Moreover, the functor $s_{q}$ is canonically isomorphic to the following composition of triangulated functors:

$$S_{q}H \xrightarrow{R} R_{C_{q}^{\text{eff}}}S_{q}H \xrightarrow{C_{q}} S^{q}S_{q}H \xrightarrow{W_{q+1}} R_{C_{q}^{\text{eff}}}S_{q}H \xrightarrow{C_{q}} S_{q}H$$
Proof. (1) and (3) follow directly from \([12, \text{Thms. 3.3.9, 3.3.25, 3.3.50, 3.3.68}]\). On the other hand, (2) follows from proposition 3.2.27(3) together with theorem 3.3.26; proposition 3.3.30 and theorem 3.3.45 in \([12]\).

2 Birational and Weakly Birational Cohomology Theories

In this section, we construct the birational and weakly birational motivic stable homotopy categories. These are defined as left Bousfield localizations of \(\text{Spt}(\mathcal{M})\) with respect to maps which are induced by open immersions with a numerical condition in the codimension of the closed complement (which is assumed to be smooth in the weakly birational case). The existence of the left Bousfield localizations considered in this section follows immediately from theorems 1.2 and 1.3.

Lemma 2.1. Let \(a,a',b,b',p,p' \geq 0\) be integers such that \(a - p = a' - p'\) and \(b - p = b' - p'\). Assume that \(p \geq p'\), then for every \(Y \in \text{Sm}_X\), there is a weak equivalence in \(\text{Spt}(\mathcal{M})\), which is natural with respect to \(Y\):

\[ g_{p,p'}^{a,b}(Y) : F_p(S^a \wedge \mathbb{G}_m^b \wedge Y_+) \to F_{p'}(S^{a'} \wedge \mathbb{G}_m^{b'} \wedge Y_+) \]

Proof. We have the following adjunction (see \([12, \text{Def. 2.6.8}]\))

\[(F_p, ev_p, \varphi) : \mathcal{M} \to \text{Spt}(\mathcal{M})\]

Using this adjunction, we define \(g_{p,p'}^{a,b}(Y)\) as adjoint to the identity map:

\[ S^a \wedge \mathbb{G}_m^b \wedge Y_+ \xrightarrow{id} ev_p(F_p(S^a \wedge \mathbb{G}_m^b \wedge Y_+)) \cong S^{p-p'} \wedge \mathbb{G}_m^{p-p'} \wedge S^{a'} \wedge \mathbb{G}_m^{b'} \wedge Y_+ \]

\[ \cong S^a \wedge \mathbb{G}_m^b \wedge Y_+ \]

Thus, it is clear that \(g_{p,p'}^{a,b}(Y)\) is natural in \(Y\), and it follows from \([12, \text{Prop. 2.4.26}]\) that it is a weak equivalence in \(\text{Spt}(\mathcal{M})\).

Definition 2.2 (see \([13, \text{section 7.5}]\)). Let \(Y \in \text{Sch}_X\), and \(Z\) a closed subscheme of \(Y\). The codimension of \(Z\) in \(Y\), \(\text{codim}_Y Z\) is the infimum (over the generic points \(z_i\) of \(Z\)) of the dimensions of the local rings \(\mathcal{O}_{Y,z_i}\).

Since \(X\) is Noetherian of finite Krull dimension and \(Y\) is of finite type over \(X\), \(\text{codim}_Y Z\) is always finite.

Definition 2.3. We fix an arbitrary integer \(n \geq 0\), and consider the following set of open immersions which have a closed complement of codimension at least \(n + 1\):

\[ B_n = \{\iota_{U,Y} : U \to Y \text{ open immersion} \mid Y \in \text{Sm}_X; Y \text{ irreducible}; (\text{codim}_Y Y \setminus U) \geq n + 1\} \]

The letter \(B\) stands for birational.
Now we consider the left Bousfield localization of \( \text{Spt}(\mathcal{M}) \) with respect to a suitable set of maps induced by the families of open immersions \( B_n \) described above.

**Definition 2.4.** Let \( n \in \mathbb{Z} \) be an arbitrary integer.

1. Let \( B_n \text{Spt}(\mathcal{M}) \) denote the left Bousfield localization of \( \text{Spt}(\mathcal{M}) \) with respect to the set of maps \( sB_n = \{ F_p(\mathbb{G}^b_m \wedge \iota_{U,Y}) : b, p, r \geq 0, b - p \geq n - r, \iota_{U,Y} \in B_r \} \).

2. Let \( b^{(n)} \) denote its fibrant replacement functor and \( \mathcal{S}H(B_n) \) its associated homotopy category.

For \( n \neq 0 \) we will call \( \mathcal{S}H(B_n) \) the codimension \( n + 1 \)-birational motivic stable homotopy category, and for \( n = 0 \) we will call it the birational motivic stable homotopy category.

**Lemma 2.5.** Let \( n \in \mathbb{Z} \) be an arbitrary integer. Then for every \( a \geq 0 \), the maps \( S^a \wedge sB_n = \{ F_p(S^a \wedge \mathbb{G}^b_m \wedge \iota_{U,Y}) : b, p, r \geq 0, b - p \geq n - r, \iota_{U,Y} \in B_r \} \) are weak equivalences in \( B_n \text{Spt}(\mathcal{M}) \).

**Proof.** Let \( F_p(\mathbb{G}^b_m \wedge \iota_{U,Y}) \in sB_n \) with \( \iota_{U,Y} \in B_r \). Both \( F_p(\mathbb{G}^b_m \wedge U_\ast) \) and \( F_p(\mathbb{G}^b_m \wedge Y_\ast) \) are cofibrant in \( \text{Spt}(\mathcal{M}) \) (see [12, Props. 2.4.17, 2.6.18 and Thm. 2.6.30]) and hence also in \( B_n \text{Spt}(\mathcal{M}) \). By construction, \( F_p(\mathbb{G}^b_m \wedge \iota_{U,Y}) \) is a weak equivalence in \( B_n \text{Spt}(\mathcal{M}) \); and [2, Thm. 4.1.1.(4)] implies that \( B_n \text{Spt}(\mathcal{M}) \) is a simplicial model category. Thus, it follows from Ken Brown’s lemma (see [4, lemma 1.1.12]) that \( F_p(S^a \wedge \mathbb{G}^b_m \wedge \iota_{U,Y}) \) is also a weak equivalence in \( B_n \text{Spt}(\mathcal{M}) \) for every \( a \geq 0 \).

**Proposition 2.6.** Let \( E \) be an arbitrary symmetric \( T \)-spectrum. Then \( E \) is fibrant in \( B_n \text{Spt}(\mathcal{M}) \) if and only if the following conditions hold:

1. \( E \) is fibrant in \( \text{Spt}(\mathcal{M}) \).

2. For every \( a, b, p, r \geq 0 \) such that \( b - p \geq n - r \); and every \( \iota_{U,Y} \in B_r \), the induced map

\[
\text{Hom}_{\mathcal{S}H}(F_p(S^a \wedge \mathbb{G}^b_m \wedge Y_\ast), E) \xrightarrow{\iota_{U,Y}^*} \text{Hom}_{\mathcal{S}H}(F_p(S^a \wedge \mathbb{G}^b_m \wedge U_\ast), E)
\]

is an isomorphism.

**Proof.** (\( \Rightarrow \)): Since the identity functor

\[
id : \text{Spt}(\mathcal{M}) \to B_n \text{Spt}(\mathcal{M})
\]

Documenta Mathematica 18 (2013) 51–70
is a left Quillen functor, the conclusion follows from the derived adjunction
\[(Q, b^{(n)}, \varphi) : \mathcal{SH} \to \mathcal{SH}(B_n)\]
together with lemma 2.5.
\((\Leftarrow)\): Assume that \(E\) satisfies (1) and (2). Let \(\omega_0, \eta_0\) denote the base points of the pointed simplicial sets \(\text{Map}_*(F_p(G^b_m \wedge Y_+), E)\) and \(\text{Map}_*(F_p(G^b_m \wedge U_+), E)\) respectively. Since \(F_p(G^b_m \wedge Y_+)\) and \(F_p(G^b_m \wedge U_+)\) are always cofibrant, by [2, Def. 3.1.4(1)(a) and Thm. 4.1.1(2)] it is enough to show that every map in \(sB_n\) induces a weak equivalence of simplicial sets:
\[
\text{Map}_*(F_p(G^b_m \wedge Y_+), E) \xrightarrow{\iota_{Y,Y}} \text{Map}_*(F_p(G^b_m \wedge U_+), E)
\]
Since \(Spt(M)\) is a pointed simplicial model category, we observe that lemma 6.1.2 in [4] and remark 2.4.3(2) in [12] imply that the following diagram is commutative for \(a \geq 0\) and all the vertical arrows are isomorphisms
\[
\begin{array}{ccc}
\pi_{a,\omega_0} \text{Map}_*(F_p(G^b_m \wedge Y_+), E) & \xrightarrow{=} & \pi_{a,\eta_0} \text{Map}_*(F_p(G^b_m \wedge U_+), E) \\
\downarrow & & \downarrow \\
\text{Hom}_{\mathcal{SH}}(F_p(S^a \wedge G^b_m \wedge Y_+), E) & \xrightarrow{\iota_{Y,Y}} & \text{Hom}_{\mathcal{SH}}(F_p(S^a \wedge G^b_m \wedge U_+), E)
\end{array}
\]
by hypothesis, the bottom row is an isomorphism, hence the top row is also an isomorphism. This implies that for every map in \(sB_n\), the induced map
\[
\text{Map}_*(F_p(G^b_m \wedge Y_+), E) \xrightarrow{\iota_{Y,Y}} \text{Map}_*(F_p(G^b_m \wedge U_+), E)
\]
is a weak equivalence when it is restricted to the path component of \(\text{Map}_*(F_p(G^b_m \wedge Y_+), E)\) containing \(\omega_0\). This holds in particular for
\[
\text{Map}_*(F_{p+1}(G^b_{m+1} \wedge Y_+), E) \xrightarrow{\iota_{Y,Y}} \text{Map}_*(F_{p+1}(G^b_{m+1} \wedge U_+), E)
\]
Therefore, the following map is a weak equivalence of pointed simplicial sets, since taking \(S^1\)-loops kills the path components that do not contain the base point
\[
\begin{array}{ccc}
\text{Map}_*(S^1, \text{Map}_*(F_{p+1}(G^b_{m+1} \wedge Y_+), E)) & \xrightarrow{=} & \text{Map}_*(S^1, \text{Map}_*(F_{p+1}(G^b_{m+1} \wedge U_+), E))
\end{array}
\]
Now, since $Spt(M)$ is a simplicial model category we deduce that the rows in the following commutative diagram are isomorphisms

$$\text{Map}_* (S^1, \text{Map}_* (F_{p+1} (G_{m}^{b+1} \wedge Y_+), E))$$

$$\cong$$

$$\text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge Y_+), E)$$

$$\text{Map}_* (S^1, \text{Map}_* (F_{p+1} (G_{m}^{b+1} \wedge U_+), E))$$

$$\cong$$

$$\text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge U_+), E)$$

Thus, by the three out of two property for weak equivalences, we conclude that

$$\text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge Y_+), E) \xrightarrow{i_{U,Y}^*} \text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge U_+), E)$$

is also a weak equivalence of pointed simplicial sets. Finally, lemma 2.1 implies that the following diagram is commutative and the vertical arrows are weak equivalences in $Spt(M)$

$$\text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge Y_+), E) \xrightarrow{i_{U,Y}^*} \text{Map}_* (F_{p+1} (S^1 \wedge G_{m}^{b+1} \wedge U_+), E)$$

$$\text{Map}_* (F_{p} (G_{m}^{b} \wedge Y_+), E) \xrightarrow{i_{U,Y}^*} \text{Map}_* (F_{p} (G_{m}^{b} \wedge U_+), E)$$

Thus, we conclude by the two out of three property for weak equivalences that the bottom arrow is also a weak equivalence in $Spt(M)$. 

**Proposition 2.7.** The homotopy category $SH(B_n)$ is a compactly generated triangulated category in the sense of Neeman [9, Def. 1.7].

**Proof.** We will prove first that $SH(B_n)$ is a triangulated category. For this, it is enough to show that the smash product with the simplicial circle induces a Quillen equivalence (see [14, sections 1.2, 1.3])

$$(- \wedge S^1, \Omega_{S^1} \varphi) : B_n Spt(M) \to B_n Spt(M)$$

It follows from [2, Thm. 4.1.1.(4)] that this adjunction is a Quillen adjunction, and the same argument as in [12, Cor. 3.2.38] (replacing [12, Prop. 3.2.32] with proposition 2.6) allows us to conclude that it is a Quillen equivalence. Finally, since $SH$ is a compactly generated triangulated category (see [12, Prop. 3.1.5]) and the identity functor is a left Quillen functor

$$id : Spt(M) \to B_n Spt(M)$$
it follows from the derived adjunction
\[(Q, b^n, \varphi) : \mathcal{SH} \to \mathcal{SH}(B_n)\]
that \(\mathcal{SH}(B_n)\) is also compactly generated, having exactly the same set of generators as \(\mathcal{SH}\).

**Definition 2.8.** We fix an arbitrary integer \(n \geq 0\), and consider the following set of open immersions with smooth closed complement of codimension at least \(n + 1\)
\[WB_n = \{\iota_{U, Y} : U \to Y \text{ open immersion} \mid Y, Z = Y \setminus U \in Sm_X; Y \text{ irreducible}; (\text{codim}_Y Z) \geq n + 1\}\]
Notice that every map in \(WB_n\) is also in \(B_n\), but the converse doesn’t hold.

The reason to consider maps \(\iota_{U, Y}\) in \(WB_n\) is that if the closed complement is smooth, then the Morel-Voevodsky homotopy purity theorem (see [8, Thm. 2.23]) characterizes the homotopy cofibre of \(\iota_{U, Y}\) in terms of the Thom space of the normal bundle for the closed immersion \(Y \setminus U \to Y\).

**Definition 2.9.** Let \(n \in \mathbb{Z}\) be an arbitrary integer.

1. Let \(WB_n Spt(M)\) denote the left Bousfield localization of \(Spt(M)\) with respect to the set of maps
\[sWB_n = \{F_p(S^a \wedge \mathbb{G}_m^b \wedge Y, E) \to \iota_{U, Y}^* F_p(S^a \wedge \mathbb{G}_m^b \wedge U, E)\}\]
where \(\iota_{U, Y} : U \to Y\) is open immersion.

2. Let \(wb^{(n)}\) denote its fibrant replacement functor and \(\mathcal{SH}(WB_n)\) its associated homotopy category.

For \(n \neq 0\) we will call \(\mathcal{SH}(WB_n)\) the \(\text{codimension} n + 1\)-weakly birational motivic stable homotopy category, and for \(n = 0\) we will call it the \(\text{weakly birational motivic stable homotopy category}\).

**Proposition 2.10.** Let \(E\) be an arbitrary symmetric \(T\)-spectrum. Then \(E\) is fibrant in \(WB_n Spt(M)\) if and only if the following conditions hold:

1. \(E\) is fibrant in \(Spt(M)\).
2. For every \(a, b, p, r \geq 0\) such that \(b - p \geq n - r\); and every \(\iota_{U, Y} \in WB_n\), the induced map
\[\text{Hom}_{\mathcal{SH}}(F_p(S^a \wedge \mathbb{G}_m^b \wedge Y, E) \to \iota_{U, Y}^* F_p(S^a \wedge \mathbb{G}_m^b \wedge U, E)\]
is an isomorphism.

**Proof.** The proof is exactly the same as in proposition 2.6. \(\square\)
Proposition 2.11. The homotopy category $\mathcal{SH}(WB_n)$ is a compactly generated triangulated category in the sense of Neeman.

Proof. The proof is exactly the same as in proposition 2.7.

Proposition 2.12. Assume that the base scheme $X = \text{Spec } k$, with $k$ a perfect field, then the Quillen adjunction:

$$(\text{id}, \text{id}, \varphi) : WB_n \text{Spt}(\mathcal{M}) \to B_n \text{Spt}(\mathcal{M})$$

is a Quillen equivalence.

Proof. Consider the following commutative diagram

$$\begin{array}{ccc}
\text{Spt}(\mathcal{M}) & \xrightarrow{\text{id}} & \text{Spt}(\mathcal{M}) \\
\downarrow \text{id} & & \downarrow \text{id} \\
WB_n \text{Spt}(\mathcal{M}) & \xrightarrow{-} & B_n \text{Spt}(\mathcal{M})
\end{array}$$

where the solid arrows are left Quillen functors. Clearly, $WB_r \subseteq B_r$ for every $r \geq 0$, so $sWB_n \subseteq sB_n$, and we conclude that every $sWB_n$-local equivalence is a $sB_n$-local equivalence. Therefore, the universal property of left Bousfield localizations implies that the horizontal arrow is also a left Quillen functor. The universal property for left Bousfield localizations also implies that it is enough to show that all the maps in

$$sB_n = \{ F_p(G_m^b \wedge \iota_{U,Y}) : b, p, r \geq 0, b - p \geq n - r; \iota_{U,Y} \in B_r \}$$

become weak equivalences in $WB_n \text{Spt}(\mathcal{M})$. Given $F_p(G_m^b \wedge \iota_{U,Y}) \in sB_n$ with $\iota_{U,Y} \in B_r$, we proceed by induction on the dimension of $Z = Y \setminus U$. If $\dim Z = 0$, then $Z \in Sm_X$ since $k$ is a perfect field (and we are considering $Z$ with the reduced scheme structure), hence $F_p(G_m^b \wedge \iota_{U,Y}) \in sWB_n$ and then a weak equivalence in $WB_n \text{Spt}(\mathcal{M})$.

If $\dim Z > 0$, then we consider the singular locus $Z_s$ of $Z$ over $X$. We have that $\dim Z_s < \dim Z$ since $k$ is a perfect field. Therefore, by induction on the dimension $F_p(G_m^b \wedge \iota_{V,Y})$ is a weak equivalence in $WB_n \text{Spt}(\mathcal{M})$, where $V = Y \setminus Z_s$. On the other hand, $F_p(G_m^b \wedge \iota_{U,V})$ is also a weak equivalence in $WB_n \text{Spt}(\mathcal{M})$ since $\iota_{U,V}$ is also in $B_r$ and its closed complement $V \setminus U = Z \setminus Z_s$ is smooth over $X$, by construction of $Z_s$.

But $F_p(G_m^b \wedge \iota_{U,Y}) = F_p(G_m^b \wedge \iota_{U,V}) \circ F_p(G_m^b \wedge \iota_{V,Y})$, so by the two out of three property for weak equivalences we conclude that $F_p(G_m^b \wedge \iota_{U,Y})$ is a weak equivalence in $WB_n \text{Spt}(\mathcal{M})$.

3 A Characterization of the Slices

This section contains our main results. We give a characterization of the slices in terms of effectivity and birational conditions (in the sense of definition 3.1), and we also show that there is an equivalence between the notion of orthogonality (see definition 1.1) and weak birationality (see definition 3.1).
Definition 3.1. Let $E \in Spt(\mathcal{M})$ be a symmetric $T$-spectrum and $n \in \mathbb{Z}$.

1. We will say that $E$ is $n+1$-birational (respectively weakly $n+1$-birational), if $E$ is fibrant in $B_n Spt(\mathcal{M})$ (respectively $WB_n Spt(\mathcal{M})$). If $n = 0$, we will simply say that $E$ is birational (respectively weakly birational).

2. We will say that $E$ is an $n$-slice if $E$ is isomorphic in $\mathcal{S}H$ to $s_n(E')$ for some symmetric $T$-spectrum $E'$.

Definition 3.2. 1. Let $\iota_{U,Y}$ be an open immersion in $Sm_X$. Let $Y/U$ denote the pushout of the following diagram in $\mathcal{M}$ (i.e. the homotopy cofibre of $\iota_{U,Y}$ in $\mathcal{M}$)

\[ \begin{array}{ccc}
U & \xrightarrow{\iota_{U,Y}} & Y \\
\downarrow & & \downarrow \\
X & \xrightarrow{=} & Y/U
\end{array} \]

2. Given a vector bundle $\pi : V \to Y$ with $Y \in Sm_X$, let $Th(V)$ denote the Thom space of $V$, i.e. $V/(V \setminus \sigma_0(Y))$, where $\sigma_0 : Y \to V$ denotes the zero section of $V$.

Lemma 3.3. Let $\iota_{U,Y} \in WB_r$ for some $r \geq 0$, and let $a, b, p \geq 0$ be arbitrary integers such that $b - p \geq n - r$.

Then

\[ F_p(S^a \wedge \mathbb{G}_m^b \wedge Y/U) \in \Sigma_{T}^{n+1} \mathcal{S}H^{eff} \]

Proof. Since $\Sigma_{T}^{n+1} \mathcal{S}H^{eff}$ is a triangulated category, it is enough to consider the case $a = 0$. It is also clear that it suffices to show that $F_0(Y/U) \in \Sigma_{T}^{r+1} \mathcal{S}H^{eff}$. Now, it follows from the Morel-Voevodsky homotopy purity theorem (see [8, Thm. 2.23]) that there is an isomorphism in $\mathcal{S}H$

\[ F_0(Y/U) \to F_0(Th(N)) \]

where $Th(N)$ is the Thom space of the normal bundle $N$ of the (smooth) complement $Z$ of $U$ in $Y$:

\[ e : Y \setminus U = Z \to Y \]

But, $\iota_{U,Y} \in WB_r$; so $e$ is a regular embedding of codimension $c$ at least $r + 1$, hence $N$ is a vector bundle of rank at least $r + 1$. Therefore, if $N$ is a trivial vector bundle we conclude from [8, Prop. 2.17(2)] that

\[ F_0(Th(N)) \cong F_0(S^c \wedge \mathbb{G}_m^c \wedge Z_+) \in \Sigma_{T}^{r+1} \mathcal{S}H^{eff} \subseteq \Sigma_{T}^{n+1} \mathcal{S}H^{eff} \]

Finally, we conclude in the general case by choosing a Zariski cover of $Z$ which trivializes $N$ and using the Mayer-Vietoris property for Zariski covers.  

Documenta Mathematica 18 (2013) 51–70
Lemma 3.4. Let $U \in Sm_X$. Consider the open immersion in $Sm_X$

$$m_U : \mathbb{A}^1_U \setminus U \to \mathbb{A}^1_U$$

given by the complement of the zero section. Then $m_U \in WB_0$, and there exists a weak equivalence in $Spt(M)$ between its homotopy cofibre in $M$, $\mathbb{A}^1_U/(\mathbb{A}^1_U \setminus U)$ and $S^1 \wedge G_m \wedge U_+$

$$t_U : \mathbb{A}^1_U/(\mathbb{A}^1_U \setminus U) \to S^1 \wedge G_m \wedge U_+$$

Proof. Since the zero section $i_0 : U \to \mathbb{A}^1_U$ is a closed embedding of codimension 1 between smooth schemes over $X$, it follows from the definition of $WB_0$ that $m_U \in WB_0$. Finally, [8, Prop. 2.17(2)] implies the existence of the weak equivalence $t_U$.

Proposition 3.5. Let $E \in Spt(M)$ be a symmetric $T$-spectrum and $n \in \mathbb{Z}$. Consider the following conditions:

1. $E$ is fibrant in $L_{<n+1}Spt(M)$.
2. $E$ is weakly $n+1$-birational (see definition 3.1(1)).
3. $E$ is $n+1$-birational (see definition 3.1(1)).

Then (1) and (2) are equivalent. In addition, if the base scheme $X = \text{Spec } k$, with $k$ a perfect field, then (1), (2) and (3) are equivalent.

Proof. (1)⇒(2): Assume that $E$ is fibrant in $L_{<n+1}Spt(M)$. By proposition 2.10 it suffices to show that for every $a, b, p, r \geq 0$ with $b - p \geq n - r$, and every $\iota_U, \iota_Y \in WB_r$; the induced map

$$\text{Hom}_{SH}(F_p(S^a \wedge G_m \wedge U_+), E) \xrightarrow{\iota_U, \iota_Y} \text{Hom}_{SH}(F_p(S^a \wedge G_m \wedge U_+), E)$$

is an isomorphism. We observe that

$$F_p(S^a \wedge G_m \wedge -) : \mathcal{M} \to Spt(M)$$

is a left Quillen functor, therefore the following

$$F_p(S^a \wedge G_m \wedge U_+) \xrightarrow{F_p(S^a \wedge G_m \wedge Y_+)} F_p(S^a \wedge G_m \wedge Y_+) \longrightarrow F_p(S^a \wedge G_m \wedge Y/U)$$

is a cofibre sequence in $Spt(M)$. However, $\mathcal{SH}$ is a triangulated category and lemma 2.1 implies that

$$F_{p+1}(S^a \wedge G_m^{b+1} \wedge Y/U) \cong \Omega_{S^1} \circ R \circ F_p(S^a \wedge G_m^{b} \wedge Y/U)$$

are isomorphic in $\mathcal{SH}$, where $R$ denotes a fibrant replacement functor in $Spt(M)$. Hence it suffices to show that

$$\text{Hom}_{SH}(F_{p+1}(S^a \wedge G_m^{b+1} \wedge Y/U), E) = \text{Hom}_{SH}(F_p(S^a \wedge G_m^{b} \wedge Y/U), E) = 0$$
Finally, it follows from lemma 3.4 that the following groups are isomorphic
of weak equivalences.

\[ \text{Hom}_{\text{SH}}(F_p(S^n \wedge G^b_m \wedge U_+), E) = 0 \]

for every \( F_p(S^n \wedge G^b_m \wedge U_+ \in C^{n+1}_{\text{eff}} \).

The same argument as in lemma 2.5 implies that it is enough to consider the
case when \( b, p \geq 1 \) and \( F_p(S^1 \wedge G^b_m \wedge U_+) \in C^{n+1}_{\text{eff}} \). In effect, if \( F_p(G^b_m \wedge U_+) \in C^{n+1}_{\text{eff}} \),
then lemma 2.1 implies that the natural map
\[ g_{p+1}^{1,b+1}(U) : F_{p+1}(S^1 \wedge G^b_m \wedge U_+) \rightarrow F_p(G^b_m \wedge U_+) \]
is a weak equivalence in \( \text{Spt}(\mathcal{M}) \).

Now, it follows from lemma 3.4, that if \( b \geq 1 \), and \( 0 - p + (b - 1) \geq n \) (i.e.
\( b - p \geq n + 1 \); then \( F_p(G^{b-1}_m \wedge mU) \in sW B_n \), i.e. a weak equivalence in \( WB_n \text{Spt}(\mathcal{M}) \).

Since \( \text{SH}(WB_n) \) is a triangulated category, \( id : \text{Spt}(\mathcal{M}) \rightarrow WB_n \text{Spt}(\mathcal{M}) \) is a
left Quillen functor, and \( F_p(G^{b-1}_m \wedge (A^1_{\text{eff}}/(A^1_{\text{eff}} \wedge U_+))) \) is the homotopy cofibre of
\( F_p(G^{b-1}_m \wedge mU) \); we deduce that \( E \) being \( n + 1 \)-weakly birational implies that
\[ \text{Hom}_{\text{SH}}(F_p(G^{b-1}_m \wedge (A^1_{\text{eff}}/(A^1_{\text{eff}} \wedge U_+))), E) = 0 \]

Finally, it follows from lemma 3.4 that the following groups are isomorphic
\[ 0 = \text{Hom}_{\text{SH}}(F_p(G^{b-1}_m \wedge (A^1_{\text{eff}}/(A^1_{\text{eff}} \wedge U_+))), E) \]
\[ \cong \text{Hom}_{\text{SH}}(F_p(S^1 \wedge G^b_m \wedge U_+), E) \]

(2)⇒(1): Assume that \( E \) is \( n + 1 \)-weakly birational. Then, proposition 3.3.30
in [12] implies that it suffices to show that
\[ \text{Hom}_{\text{SH}}(F_p(S^n \wedge G^b_m \wedge U_+), E) = 0 \]

But this follows from lemma 3.3 together with [12, Prop. 3.3.30], since we are
assuming that \( E \) is fibrant in \( L_{<n+1} \text{Spt}(\mathcal{M}) \).

\[ \text{The Quillen adjunction} \]
\[ (id, id, \varphi) : WB_n \text{Spt}(\mathcal{M}) \rightarrow L_{<n+1} \text{Spt}(\mathcal{M}) \]
is a Quillen equivalence. In addition, if the base scheme \( X = \text{Spec } k \), with \( k \) a
perfect field, then the Quillen adjunction
\[ (id, id, \varphi) : B_n \text{Spt}(\mathcal{M}) \rightarrow L_{<n+1} \text{Spt}(\mathcal{M}) \]
is also a Quillen equivalence.

Proof. We show first that \( WB_n \text{Spt}(\mathcal{M}) \) and \( L_{<n+1} \text{Spt}(\mathcal{M}) \) are Quillen equivalent.
Since \( WB_n \text{Spt}(\mathcal{M}) \), \( L_{<n+1} \text{Spt}(\mathcal{M}) \) are both left Bousfield localizations of \( \text{Spt}(\mathcal{M}) \), we deduce that they are simplicial model categories with the same
cofibrant replacement functor \( Q \). Thus, it suffices to show that they have the
same class of weak equivalences.

Documenta Mathematica 18 (2013) 51–70
However, proposition 3.5 implies that $WB_n Spt(M)$, and $L_{<n+1} Spt(M)$ also have the same class of fibrant objects. Therefore, it follows from [2, Thm. 9.7.4] that they have exactly the same class of weak equivalences.

Finally, if the base scheme is a perfect field, by proposition 2.12 we conclude that $WB_n Spt(M)$ and $B_n Spt(M)$ are Quillen equivalent.

**Theorem 3.7.** Let $E$ be fibrant in $Spt(M)$. Then $E$ is an $n$-slice (see definition 3.1(2)) if and only if the following conditions hold:

S1 $E$ is $n$-effective, i.e. $E \in \Sigma^n TSH^{eff}$.

S2 $E$ is $n+1$-weakly birational.

In addition, if the base scheme $X = \text{Spec } k$, with $k$ a perfect field, then $E$ is an $n$-slice if and only if the following conditions hold:

GSS1 $E$ is $n$-effective, i.e. $E \in \Sigma^n_T SH^{eff}$.

GSS2 $E$ is $n+1$-birational.

**Proof.** Assume that $E$ is an $n$-slice. Then theorems 1.4(1) and 1.4(3) imply that $E$ is $n$-effective and fibrant in $L_{<n+1} Spt(M)$.

Hence, proposition 3.5 implies that $E$ is also $n+1$-weakly birational.

Now we assume that $E$ satisfies the conditions S1 and S2 above. Then, proposition 3.5 implies that $E$ is fibrant in $L_{<n+1} Spt(M)$. Therefore, theorem 1.4(3) implies that $E$ is isomorphic in $SH$ to its own $n$-slice $s_n(E)$.

Finally, if the base scheme is a perfect field, then by proposition 3.5 the conditions S2 and GSS2 are equivalent; hence we can conclude applying the same argument as above.

**Remark 3.8.** Notice that theorem 3.6 implies that it is possible to construct the slice filtration directly from the Quillen model categories $WB_n Spt(M)$ described in definition 2.9 without making any reference to the effective categories $\Sigma^n TSH^{eff}$. One of the interesting consequences of this fact is that it is possible to obtain analogues of the slice filtration in the unstable setting, since the suspension with respect to $T$ or $S^1$ does not play an essential role in the construction of $WB_n Spt(M)$, i.e. we could consider the left Bousfield localization of the motivic unstable homotopy category $M$ with respect to the maps in definition 2.8. We will study the details of this construction in a future work.

4 Some Computations

In this section we use the characterization of the slices obtained in theorem 3.7 to describe the slices of projective spaces, Thom spaces and blow ups.

To simplify the notation, given a simplicial presheaf $K \in M$ or a map $f \in M$; let $s_j(K)$, $s_j(f)$ (respectively $s_{<j}(K)$, $s_{<j}(f)$) denote $s_j(F_0(K))$, $s_j(F_0(f))$ (respectively $s_{<j}(F_0(K))$, $s_{<j}(F_0(f))$).
Lemma 4.1. Let \( g : E \to F \) be a map in \( SH \) such that \( s_{<n}(g) \) and \( s_{<n+1}(g) \) are both isomorphisms in \( SH \). Then the \( n \)-slice of \( g \), \( s_n(g) \) is also an isomorphism in \( SH \).

Proof. It follows from [12, Prop. 3.1.19] that the rows in the following commutative diagram are distinguished triangles in \( SH \)

\[
\begin{array}{cccc}
s_n(E) & s_{<n+1}(E) & s_{<n}(E) & S^1 \land s_n(E) \\
\downarrow s_n(g) & \downarrow s_{<n+1}(g) & \downarrow s_{<n}(g) & \downarrow S^1 \land s_n(g) \\
s_n(F) & s_{<n+1}(F) & s_{<n}(F) & S^1 \land s_n(F)
\end{array}
\]

Thus, we conclude that \( s_n(g) \) is also an isomorphism in \( SH \).

Consider \( Y \in Sm_X \). Let \( \mathbb{P}^n(Y) \) denote the trivial projective bundle of rank \( n \) over \( Y \), and let \( \mathbb{P}^\infty(Y) \) denote the colimit in \( M \) of the following filtered diagram

\[
\mathbb{P}^0(Y) \to \mathbb{P}^1(Y) \to \cdots \to \mathbb{P}^n(Y) \to \cdots
\]

given by the inclusions of the respective hyperplanes at infinity.

Theorem 4.2. Let \( Y \in Sm_X \). Then for any integer \( j \leq n \), the diagram 4.1 induces the following isomorphisms in \( SH \)

\[
s_j(\mathbb{P}^n(Y)_+) \cong s_j(\mathbb{P}^{n+1}(Y)_+) \cong \cdots \cong s_j(\mathbb{P}^\infty(Y)_+)
\]

Proof. Let \( k > n \), and consider the closed embedding induced by the diagram (4.1) \( \lambda^k_n : \mathbb{P}^n(Y) \to \mathbb{P}^k(Y) \). It is possible to choose a linear embedding \( \mathbb{P}^{k-n-1}(Y) \to \mathbb{P}^k(Y) \) such that its open complement \( U_{k,n} \) contains \( \mathbb{P}^n(Y) \) and has the structure of a vector bundle over \( \mathbb{P}^n(Y) \), with zero section \( \sigma^k_n \):

\[
\begin{array}{ccc}
U_{k,n} & \xrightarrow{s_n^k} & \mathbb{P}^k(Y) \\
\downarrow \sigma^k_n & & \downarrow \lambda^k_n \\
\mathbb{P}^n(Y) & & \mathbb{P}^{k-n-1}(Y)
\end{array}
\]

By homotopy invariance \( s_{<j}(\sigma^k_n) \) is an isomorphism in \( SH \) for every integer \( j \). On the other hand, if \( j \leq n \), then \( F_0(v^k_n) \) is a weak equivalence in \( WB_j Spt(M) \) since the codimension of its closed complement is \( n+1 \). Thus, theorems 1.4(2) and 3.6 imply that if \( j \leq n + 1 \), then \( s_{<j}(v^k_n) \) is also an isomorphism in \( SH \).

Therefore, \( s_{<j}(\lambda^k_n) = s_{<j}(v^k_n) \circ s_{<j}(\sigma^k_n) \) is an isomorphism in \( SH \) for \( j \leq n+1 \); and using lemma 4.1 we conclude that the induced map on the slices \( s_j(\lambda^k_n) \) is also an isomorphism for \( j \leq n \).

Finally, the result for \( \mathbb{P}^\infty(Y) \) follows directly from the fact that the slices commute with filtered homotopy colimits.

\[
Documenta Mathematica 18 (2013) 51–70
\]
Let $HZ$ denote Voevodsky’s Eilenberg-MacLane spectrum (see [15, section 6.1]) representing motivic cohomology in $\mathcal{SH}$.

**Corollary 4.3.** Assume that the base scheme $X = \text{Spec } k$, with $k$ a perfect field. Then, in the following diagram all the symmetric $T$-spectra are isomorphic to $HZ$:

$$
HZ \xrightarrow{\cong} s_0(\mathbb{P}^0(k)_+) \xrightarrow{\cong} s_0(\mathbb{P}^1(k)_+) \xrightarrow{\cong} \cdots
$$

$$
\cdots \xrightarrow{\cong} s_0(\mathbb{P}^n(k)_+) \xrightarrow{\cong} \cdots \xrightarrow{\cong} s_0(\mathbb{P}^{\infty}(k)_+)
$$

**Proof.** This follows immediately from theorem 4.2 together with the computation of Levine [7, Thm. 10.5.1] and Voevodsky [17] for the zero slice of the sphere spectrum.

**Theorem 4.4.** Let $\omega_{U,Y} \in WB_n$, $\pi : V \to Y$ a vector bundle of rank $r$ together with a trivialization $t : \pi^{-1}(U) \to \mathbb{A}^r_U$ of its restriction to $U$. Then for every integer $j \leq n$, there exists an isomorphism in $\mathcal{SH}$ (see definition 3.2(2))

$$s_j(Th(V)) \cong S^r \wedge \mathbb{G}_m^r \wedge s_{j-r}(Y_+)$$

**Proof.** Let $Z \in Sm_X$ be the closed complement of $\omega_{U,Y}$. Consider the following diagram in $Sm_X$, where all the squares are cartesian

$$
\begin{array}{ccc}
\pi^{-1}(Z) \cap (V \setminus \sigma_0(Y)) & \xrightarrow{$\beta$} & \pi^{-1}(U) \cap (V \setminus \sigma_0(Y)) \\
\downarrow & & \downarrow \\
\pi^{-1}(Z) & \xrightarrow{$\alpha$} & \pi^{-1}(U) \\
\downarrow & & \downarrow \\
Z & \xrightarrow{$\pi$} & Y \xrightarrow{$\omega_{U,Y}$} U
\end{array}
$$

and let $\gamma : Th(\pi^{-1}(U)) \to Th(V)$ be the induced map between the corresponding Thom spaces. We observe that $\alpha, \beta$ also belong to $WB_n$; thus, if $j \leq n$ we conclude that $F_0(\omega_{U,Y}), F_0(\alpha), F_0(\beta)$ are all weak equivalences in $WB_j \text{spt}(\mathcal{M})$. Therefore, theorems 1.4(2) and 3.6 imply that if $j \leq n+1$, then $s_{<j}(\omega_{U,Y}), s_{<j}(\alpha), s_{<j}(\beta)$ are isomorphisms in $\mathcal{SH}$. We claim that if $j \leq n+1$, then

$$s_{<j}(\gamma) : s_{<j}(Th(\pi^{-1}(U))) \to s_{<j}(Th(V))$$

is also an isomorphism in $\mathcal{SH}$. In effect, by construction of the Thom spaces, we deduce that for any integer $j \in \mathbb{Z}$, the rows in the following commutative diagram in $\mathcal{SH}$ are in fact distinguished triangles

$$
\begin{array}{ccc}
s_{<j}(\pi^{-1}(U) \cap (V \setminus \sigma_0(Y)))_+ & \xrightarrow{s_{<j}(\pi^{-1}(U)_+)} & s_{<j}(Th(\pi^{-1}(U))) \\
\downarrow & & \downarrow \\
s_{<j}(\sigma_0(Y)_+)_+ & \xrightarrow{s_{<j}(\sigma_0(Y)_+)} & s_{<j}(Th(V)) \\
\downarrow & & \downarrow \\
s_{<j}(V)_+ & \xrightarrow{s_{<j}(\gamma)} & s_{<j}(Th(V))
\end{array}
$$
Since \( s_{<j}(\alpha), s_{<j}(\beta) \) are isomorphisms in \( \mathcal{SH} \) for \( j \leq n + 1 \), we conclude that for \( j \leq n + 1 \), \( s_{<j}(\gamma) \) is also an isomorphism in \( \mathcal{SH} \). Thus, lemma 4.1 implies that for \( j \leq n \), \( s_j(U,Y) \), \( s_j(\gamma) \) are isomorphisms in \( \mathcal{SH} \). Now, we use the trivialization \( t \) to obtain the following commutative diagram in \( Sm_X \) where the rows are isomorphisms

\[
\begin{array}{c}
K_U \setminus U & \overset{\approx}{\rightarrow} & \pi^{-1}(U) \cap (V \setminus \sigma_0(Y)) \\
\downarrow & & \downarrow \\
K_U & \overset{\approx}{\rightarrow} & \pi^{-1}(U) \\
\downarrow & & \downarrow \\
U & \overset{\pi_U}{\rightarrow} & \pi^{-1}(U)
\end{array}
\]

The same argument as above, shows that for every integer \( j \in \mathbb{Z} \), there is an isomorphism in \( \mathcal{SH} \)

\[
s_j(t) : s_j(Th(\pi^{-1}(U))) \rightarrow s_j(Th(K_U))
\]

On the other hand, [8, Prop. 2.17(2)] implies that there is a weak equivalence \( w : F_0(Th(K_U)) \rightarrow S^r \wedge G^r_m \wedge F_0(U_+) \) in \( Spt(M) \). Thus, for \( j \leq n \) there exist isomorphisms in \( \mathcal{SH} \)

\[
s_j(Th(\pi^{-1}(U))) \overset{s_j(t)}{\rightarrow} s_j(Th(K_U)) \overset{s_j(\gamma)}{\downarrow} s_j(Th(V)) \overset{s_j(w)}{\rightarrow} s_j(S^r \wedge G^r_m \wedge U_+) \]

However, there exists a canonical isomorphism in \( \mathcal{SH} \)

\[
s_j(S^r \wedge G^r_m \wedge U_+) \rightarrow S^r \wedge G^r_m \wedge s_j-r(U_+)
\]

Finally, we conclude by using the isomorphism \( s_{j-r}(t_{U,Y}) \) (notice that if \( j \leq n \) then certainly \( j - r \leq n \), since \( r \geq 0 \)).

**Corollary 4.5.** Assume that the base scheme \( X = \text{Spec} \ k \), with \( k \) a perfect field. Let \( t_{U,Y} \in B_n, \pi : V \rightarrow Y \) a vector bundle of rank \( r \) together with a trivialization \( t : \pi^{-1}(U) \rightarrow K_U \) of its restriction to \( U \). Then for every integer \( j \leq n \), there exists an isomorphism in \( \mathcal{SH} \)

\[
s_j(Th(V)) \cong S^r \wedge G^r_m \wedge s_j-r(Y_+).
\]

**Proof.** Proposition 2.12 implies that \( F_0(t_{U,Y}) \) is a weak equivalence in \( WB_j Spt(M) \) for \( j \leq n \). Hence, the result follows using exactly the same argument as in theorem 4.4. \( \square \)
Given a closed embedding $Z \to Y$ of smooth schemes over $X$, let $\mathcal{B}ZY$ denote the blowup of $Y$ with center in $Z$.

**Theorem 4.6.** Let $i_{U,Y} \in WB_n$ with closed complement $Z$, and $j \in \mathbb{Z}$ an arbitrary integer. Consider the following cartesian square in $\text{Sm}_X$

$$
\begin{array}{ccc}
D & \xrightarrow{d} & \mathcal{B}ZY \\
\downarrow q & & \downarrow u \\
Z & \xrightarrow{i} & Y
\end{array}
$$

(4.2)

and let $q_j, d_j, p_j, i_j$ denote $s_j(q), s_j(d), s_j(p), s_j(i)$ respectively. Then the cartesian square (4.2) induces the following distinguished triangle in $\mathcal{SH}$

$$
s_j(D_{+}) \xrightarrow{\left(\frac{d}{q_j}\right)} s_j(\mathcal{B}ZY_{+}) \oplus s_j(Z_{+}) \xrightarrow{\left(\frac{p_j}{i_j}\right)} s_j(Y_{+})
$$

(4.3)

If $j \leq n$, then $s_j(i_{U,Y})$ is an isomorphism in $\mathcal{SH}$, and the following distinguished triangles in $\mathcal{SH}$ split

$$
s_j(D_{+}) \xrightarrow{\left(\frac{d}{q_j}\right)} s_j(\mathcal{B}ZY_{+}) \oplus s_j(Z_{+}) \xrightarrow{\left(\frac{p_j}{i_j}\right)} s_j(Y_{+})
$$

(4.4)

$$
s_j(Y_{+}) \xrightarrow{r_j} s_j(\mathcal{B}ZY_{+}) \xrightarrow{\left(\frac{d}{q_j}\right)} s_j(Y_{+})
$$

(4.5)

where $r_j = s_j(u) \circ (s_j(i_{U,Y}))^{-1}$, and $O_D(1)$ denotes the canonical line bundle of the projective bundle $q : D \to Z$.

**Proof.** It follows from [8, Prop. 2.29 and Rmk. 2.30] that the following square is homotopy cocartesian in $\mathcal{M}$

$$
\begin{array}{ccc}
S^1 \wedge D_{+} & \xrightarrow{id \wedge d} & S^1 \wedge \mathcal{B}ZY_{+} \\
\downarrow id \wedge q & & \downarrow id \wedge p \\
S^1 \wedge Z_{+} & \xrightarrow{id \wedge i} & S^1 \wedge Y_{+}
\end{array}
$$

Thus, we deduce that the following diagram is a distinguished triangle in $\mathcal{SH}$

$$
F_0(D_{+}) \xrightarrow{\left(\frac{d}{q_j}\right)} F_0(\mathcal{B}ZY_{+}) \oplus F_0(Z_{+}) \xrightarrow{\left(\frac{p_j}{i_j}\right)} F_0(Y_{+})
$$

Since the slices $s_j$ are triangulated functors, it follows that diagram (4.3) is a distinguished triangle in $\mathcal{SH}$.
Now, we prove that $s_j(\iota U, Y)$ is an isomorphism for $j \leq n$. By lemma 4.1, it suffices to show that $s_{<j}(\iota U, Y)$ is an isomorphism in $\mathcal{SH}$ for $j \leq n + 1$. But this follows directly from theorems 3.6 and 1.4(2) since $F_0(\iota U, Y)$ is clearly a weak equivalence in $WB_j Spt(M)$ for $j \leq n$.

Thus, $r_j$ is well defined for $j \leq n$, and the following diagram shows that it gives a splitting for the distinguished triangle (4.4)

\[
\begin{array}{ccc}
    s_j(U_+) & \xrightarrow{s_j(u)} & s_j(B\ell Z Y) \\
    \downarrow & & \downarrow p_j \\
    s_j(U_+) & \xrightarrow{s_j(\iota U, Y)} & s_j(Y) \\
\end{array}
\] (4.6)

Finally, since the normal bundle of the closed embedding $d : D \to B\ell Z Y$ is given by $O_D(1)$, we deduce from the Morel-Voevodsky homotopy purity theorem (see [8, Thm. 2.23]) that the following diagram is a distinguished triangle in $\mathcal{SH}$

\[
s_j(U_+) \xrightarrow{s_j(u)} s_j(B\ell Z Y) \rightarrow s_j(Th(O_D(1)))
\]

Combining this distinguished triangle with diagram (4.6) above, we conclude that diagram (4.5) is a split distinguished triangle in $\mathcal{SH}$ for $j \leq n$.

**Acknowledgements**

The author would like to thank Marc Levine for bringing to his attention the connection between slices and birational cohomology theories, as well as for all his stimulating comments and questions, and also thank Chuck Weibel for his interest in this work and several suggestions which helped to improve the exposition.

COHERENCE FOR WEAK UNITS

ANDRÉ JOYAL AND JOACHIM KOCK

Received: September 21, 2011
Communicated by Stefan Schwede

Abstract. We define weak units in a semi-monoidal 2-category $C$ as cancellable pseudo-idempotents: they are pairs $(I, \alpha)$ where $I$ is an object such that tensoring with $I$ from either side constitutes a biequivalence of $C$, and $\alpha : I \otimes I \to I$ is an equivalence in $C$. We show that this notion of weak unit has coherence built in: Theorem A: $\alpha$ has a canonical associator 2-cell, which automatically satisfies the pentagon equation. Theorem B: every morphism of weak units is automatically compatible with those associators. Theorem C: the 2-category of weak units is contractible if non-empty. Finally we show (Theorem E) that the notion of weak unit is equivalent to the notion obtained from the definition of tricategory: $\alpha$ alone induces the whole family of left and right maps (indexed by the objects), as well as the whole family of Kelly 2-cells (one for each pair of objects), satisfying the relevant coherence axioms.

2010 Mathematics Subject Classification: 18D05; 18D10
Keywords and Phrases: Monoidal 2-categories, units, coherence.

Introduction

The notion of tricategory, introduced by Gordon, Power, and Street [2] in 1995, seems still to represent the highest-dimensional explicit weak categorical structure that can be manipulated by hand (i.e. without methods of homotopy theory), and is therefore an important test bed for higher-categorical ideas. In this work we investigate the nature of weak units at this level. While coherence for weak associativity is rather well understood, thanks to the geometrical insight provided by the Stasheff associahedra [12], coherence for unit structures is more mysterious, and so far there seems to be no clear geometric pattern for the coherence laws for units in higher dimensions. Specific interest in weak units
stems from Simpson’s conjecture [11], according to which strict \( n \)-groupoids with weak units should model all homotopy \( n \)-types.

In the present paper, working in the setting of a strict 2-category \( \mathscr{C} \) with a strict tensor product, we define a notion of weak unit by simple axioms that involve only the notion of equivalence, and hence in principle make sense in all dimensions. Briefly, a weak unit is a cancellable pseudo-idempotent. We work out the basic theory of such units, and compare with the notion extracted from the definition of tricategory. In the companion paper Weak units and homotopy 3-types [4] we employ this notion of unit to prove a version of Simpson’s conjecture for 1-connected homotopy 3-types, which is the first nontrivial case. The strictness assumptions of the present paper should be justified by that result.

By cancellable pseudo-idempotent we mean a pair \((I, \alpha)\) where \(I\) is an object in \( \mathscr{C} \) such that tensoring with \(I\) from either side is an equivalence of 2-categories, and \( \alpha : I \otimes I \cong I \) is an equi-arrow (i.e. an arrow admitting a pseudo-inverse).

The remarkable fact about this definition is that \(\alpha\), viewed as a multiplication map, comes with canonical higher order data built in: it possesses a canonical associator \(A\) which automatically satisfies the pentagon equation. This is our Theorem A. The point is that the arrow \(\alpha\) alone, thanks to the cancellability of \(I\), induces all the usual structure of left and right constraints with all the 2-cell data that goes into them and the axioms they must satisfy.

As a warm-up to the various constructions and ideas, we start out in Section 1 by briefly running through the corresponding theory for cancellable-idempotent units in monoidal 1-categories. This theory has been treated in detail in [8].

The rest of the paper is dedicated to the case of monoidal 2-categories. In Section 2 we give the definitions and state the main results: Theorem A says that there is a canonical associator 2-cell for \(\alpha\), and that this 2-cell automatically satisfies the pentagon equation. Theorem B states that unit morphisms automatically are compatible with the associators of Theorem A. Theorem C states that the 2-category of units is contractible if non-empty. Hence, ‘being unital’ is, up to homotopy, a property rather than a structure.

Next follow three sections dedicated to proofs of each of these three theorems. In Section 3 we show how the map \(\alpha : II \cong I\) alone induces left and right constraints, which in turn are used to construct the associator and establish the pentagon equation. The left and right constraints are not canonical, but surprisingly the associator does not depend on the choice of them. In Section 4 we prove Theorem B by interpreting it as a statement about units in the 2-category of arrows, where it is possible to derive it from Theorem A. In Section 5 we prove Theorem C. The key ingredient is to use the left and right constraints to link up all the units, and to show that the unit morphisms are precisely those compatible with the left and right constraints; this makes them ‘essentially unique’ in the required sense.
In Section 6 we go through the basic theory of classical units (i.e. as extracted from the definition of tricategory [2]). Finally, in Section 7 we show that the two notions of unit are equivalent. This is our Theorem E. A curiosity implied by the arguments in this section is that the left and right axioms for the 2-cell data in the Gordon-Power-Street definition (denoted TA2 and TA3 in [2]) imply each other.

(We have no Theorem D.)

This notion of weak units as cancellable idempotents is precisely what can be extracted from the more abstract, Tamsamani-style, theory of fair $n$-categories [7] by making an arbitrary choice of a fixed weak unit. In the theory of fair categories, the key object is a contractible space of all weak units, rather than any particular point in that space, and handling this space as a whole bypasses coherence issues. However, for the sake of understanding what the theory entails, and for the sake of concrete computations, it is interesting to make a choice and study the ensuing coherence issues, as we do in this paper. The resulting approach is very much in the spirit of the classical theory of monoidal categories, bicategories, and tricategories, and provides some new insight to these theories. To stress this fact we have chosen to formulate everything from scratch in such classical terms, without reference to the theory of fair categories.

In the case of monoidal 1-categories, the cancellable-idempotent viewpoint on units goes back to Saavedra [10]. The importance of this viewpoint in higher categories was first suggested by Simpson [11], in connection with his weak-unit conjecture. He gave an ad hoc definition in this style, as a mere indication of what needed to be done, and raised the question of whether higher homotopical data would have to be specified. The surprising answer is, at least here in dimension 3, that specifying $\alpha$ is enough, then the higher homotopical data is automatically built in.

ACKNOWLEDGEMENTS. We thank Georges Maltsiniotis for pointing out to us that the cancellable-idempotent notion of unit in dimension 1 goes back to Saavedra [10], and we thank Josep Elgueta for catching an error in an earlier version of our comparison with tricategories. The first-named author was supported by the NSERC. The second-named author was very happy to be a CIRGET postdoc at the UQAM in 2004, and currently holds support from grants MTM2009-10359 and MTM2010-20692 of Spain.

1 Units in monoidal categories

It is helpful first briefly to recall the relevant results for monoidal categories, referring the reader to [8] for further details of this case.

1.1. Semi-monoidal categories. A semi-monoidal category is a category $\mathcal{C}$ equipped with a tensor product (which we denote by plain juxtaposition),
i.e. an associative functor

\[ C \times C \rightarrow C \]

\((X,Y) \mapsto XY.\)

For simplicity we assume strict associativity, \(X(YZ) = (XY)Z.\)

1.2. **Monoidal categories.** (Mac Lane [9].) A semi-monoidal category \(C\) is a **monoidal category** when it is furthermore equipped with a distinguished object \(I\) and natural isomorphisms

\[ IX \overset{\lambda_X}{\longrightarrow} X \overset{\rho_X}{\longleftarrow} XI \]

obeying the following rules (cf. [9]):

\[ \lambda_I = \rho_I \quad (1) \]
\[ \lambda_{XY} = \lambda_X Y \quad (2) \]
\[ \rho_{XY} = X \rho_Y \quad (3) \]
\[ X \lambda_Y = \rho_X Y \quad (4) \]

Naturality of \(\lambda\) and \(\rho\) implies

\[ \lambda_{IX} = I \lambda_X, \quad \rho_{XI} = \rho_X I, \quad (5) \]

independently of Axioms (1)–(4).

1.3 **Remark.** Tensoring with \(I\) from either side is an equivalence of categories.

1.4 **Lemma.** (Kelly [5].) Axiom (4) implies axioms (1), (2), and (3).

**Proof.** (4) implies (2): Since tensoring with \(I\) on the left is an equivalence, it is enough to prove \(I\lambda_{XY} = I\lambda_X Y\). But this follows from Axiom (4) applied twice (swap \(\lambda\) out for a \(\rho\) and swap back again only on the nearest factor):

\[ I\lambda_{XY} = \rho_I XY = I\lambda_X Y. \]

Similarly for \(\rho\), establishing (3).

(4) and (2) implies (1): Since tensoring with \(I\) on the right is an equivalence, it is enough to prove \(\lambda_I I = \rho_I I\). But this follows from (2), (5), and (4):

\[ \lambda_I I = \lambda_{II} = I\lambda_I = \rho_I I. \]

The following alternative notion of unit object goes back to Saavedra [10]. A thorough treatment of the notion was given in [8].
1.5. Units as cancellable pseudo-idempotents. An object $I$ in a semi-monoidal category $\mathcal{C}$ is called **cancellable** if the two functors $\mathcal{C} \to \mathcal{C}$

\[
\begin{align*}
X & \longrightarrow IX \\
X & \longrightarrow XI
\end{align*}
\]

are fully faithful. By definition, a **pseudo-idempotent** is an object $I$ equipped with an isomorphism $\alpha : II \cong I$. Finally we define a **unit object** in $\mathcal{C}$ to be a cancellable pseudo-idempotent.

1.6 Lemma. [8] Given a unit object $(I, \alpha)$ in a semi-monoidal category $\mathcal{C}$, for each object $X$ there are unique arrows $\lambda_X : IX \to XI$ and $\rho_X : XI \to IX$ such that

\[
\begin{align*}
(L) & \quad I\lambda_X = \alpha X \\
(R) & \quad \rho_X I = X\alpha.
\end{align*}
\]

The $\lambda_X$ and $\rho_X$ are isomorphisms and natural in $X$.

**Proof.** Let $L : \mathcal{C} \to \mathcal{C}$ denote the functor defined by tensoring with $I$ on the left. Since $L$ is fully faithful, we have a bijection

\[
\text{Hom}(IX, X) \to \text{Hom}(II X, IX).
\]

Now take $\lambda_X$ to be the inverse image of $\alpha X$; it is an isomorphism since $\alpha X$ is. Naturality follows by considering more generally the bijection

\[
\text{Nat}(L, \text{id}_\mathcal{C}) \to \text{Nat}(L \circ L, L);
\]

let $\lambda$ be the inverse image of the natural transformation whose components are $\alpha X$. Similarly on the right. $\square$

1.7 Lemma. [8] For $\lambda$ and $\rho$ as above, the Kelly axiom (4) holds:

\[
X\lambda_Y = \rho_X Y.
\]

Therefore, by Lemma 1.6 a semi-monoidal category with a unit object is a monoidal category in the classical sense.

**Proof.** In the commutative square

\[
\begin{array}{ccc}
XIIY & \xrightarrow{XI\lambda_Y} & XIY \\
\rho_X Y \downarrow & & \rho_X Y \\
XIY & \xrightarrow{X\lambda_Y} & XY
\end{array}
\]
the top arrow is equal to $X\alpha Y$, by $X$ tensor $(L)$, and the left-hand arrow is also equal to $X\alpha Y$, by $(R)$ tensor $Y$. Since $X\alpha Y$ is an isomorphism, it follows that $X\lambda Y = \rho_X Y$.

1.8 Lemma. For a unit object $(I, \alpha)$ we have: (i) The map $\alpha : II \to I$ is associative. (ii) The two functors $X \mapsto IX$ and $X \mapsto XI$ are equivalences.

Proof. Since $\alpha$ is invertible, associativity amounts to the equation $I\alpha = \alpha I$, which follows from the previous proof by setting $X = Y = I$ and applying $L$ and $R$ once again. To see that $L$ is an equivalence, just note that it is isomorphic to the identity via $\lambda$.

1.9. Uniqueness of units. Just as in a semi-monoid a unit element is unique if it exists, one can show [8, 2.20] that in a semi-monoidal category, between any two units there is a unique isomorphism of units. This statement does not involve $\lambda$ and $\rho$, but the proof does: the canonical isomorphism $I \cong J$ is the composite $I \sim IJ \lambda_J \to J$.

2 Units in monoidal 2-categories: definition and main results

In this section we set up the necessary terminology and notation, give the main definition, and state the main results.

2.1. 2-categories. We work in a strict 2-category $\mathscr{C}$. We use the symbol $#$ to denote composition of arrows and horizontal composition of 2-cells in $\mathscr{C}$, always written from the left to the right, and occasionally decorating the symbol $#$ by the name of the object where the two arrows or 2-cells are composed. By an equi-arrow in $\mathscr{C}$ we understand an arrow $f$ admitting an (unspecified) pseudo-inverse, i.e. an arrow $g$ in the opposite direction such that $f#g$ and $g#f$ are isomorphic to the respective identity arrows, and such that the comparison 2-cells satisfy the usual triangle equations for adjunctions. (The usual word for ‘equi-arrow’ is of course ‘equivalence’; we reserve the latter word for equivalence of categories and 2-categories. We find it useful to have a different word for the equivalences inside a 2-category.) It is worth pointing out that it is not necessary to insist on the triangle equations. If the 2-cells exist but do not satisfy the triangle equation, they can always be replaced by 2-cells that do. We shall make extensive use of arguments with pasting diagrams [6]. Our drawings of 2-cells should be read from bottom to top, so that for example

\[
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow{f} & & \downarrow{g} \\
U & \xrightarrow{U} & Y \\
\end{array}
\]

denotes $U : f \# g \Rightarrow h$. The symbol $\circ$ will denote identity 2-cells.
The few 2-functors we need all happen to be strict. By *natural transformation* we always mean pseudo-natural transformation. Hence a natural transformation $u : F \Rightarrow G$ between two 2-functors from $\mathcal{D}$ to $\mathcal{C}$ is given by an arrow $u_X : FX \to GX$ for each object $X \in \mathcal{D}$, and an invertible 2-cell

\[
\begin{array}{ccc}
FX & \xrightarrow{u_X} & GX \\
\downarrow{F(x)} & & \downarrow{G(x)} \\
FX' & \xrightarrow{u_{X'}} & GX'
\end{array}
\]

for each arrow $x : X \to X'$ in $\mathcal{D}$, subject to the usual compatibility conditions [6]. The modifications we shall need will happen to be invertible.

2.2. Semi-monoidal 2-categories. By *semi-monoidal 2-category* we mean a 2-category $\mathcal{C}$ equipped with a tensor product, i.e. an associative 2-functor

\[
\otimes : \mathcal{C} \times \mathcal{C} \longrightarrow \mathcal{C}
\]

\[
\begin{array}{ccc}
(X,Y) & \mapsto & XY,
\end{array}
\]

denoted by plain juxtaposition. We already assumed $\mathcal{C}$ to be a strict 2-category, and we also require $\otimes$ to be a strict 2-functor and to be strictly associative: $(XY)Z = X(YZ)$. This is mainly for convenience, to keep the focus on unit issues.

Note that the tensor product of two equi-arrows is again an equi-arrow, since its pseudo-inverse can be taken to be the tensor product of the pseudo-inverses.

2.3. Semi-monoids. A *semi-monoid* in $\mathcal{C}$ is a triple $(X, \alpha, \tilde{\alpha})$ consisting of an object $X$, a multiplication map $\alpha : XX \to X$, and an invertible 2-cell $\tilde{\alpha}$ called the *associator*,

\[
\begin{array}{ccc}
XXX & \xrightarrow{\alpha X} & XX \\
\downarrow{x_\alpha} & & \downarrow{\alpha} \\
XX & \xrightarrow{\alpha} & X
\end{array}
\]

required to satisfy the ‘pentagon equation’:

\[
\begin{array}{ccc}
XXX & \xrightarrow{\alpha X} & XXX \\
\downarrow{x_\alpha} & & \downarrow{\alpha} \\
XX & \xrightarrow{\alpha} & X
\end{array}
= 
\begin{array}{ccc}
XXX & \xrightarrow{\alpha X} & XXX \\
\downarrow{x_\alpha} & & \downarrow{\alpha} \\
XX & \xrightarrow{\alpha} & X
\end{array}
\]
In the applications, $\alpha$ will be an equi-arrow, and hence we will have

$$\tilde{A} = A \#_{XX} \alpha$$

for a some unique invertible

$$A : X \alpha \Rightarrow \alpha X,$$

which it will more convenient to work with. In this case, the pentagon equation is equivalent to the more compact equation

$$XXX \alpha_{XX} \tilde{A} \alpha_{XX} = XXX \alpha_{XX} (\circlearrowright) X \alpha_{XX}$$

which we shall also make use of.

2.4. **Semi-monoid maps.** A *semi-monoid map* $f : (X, \alpha, \tilde{A}) \to (Y, \beta, \tilde{B})$ is the data of an arrow $f : X \to Y$ in $\mathcal{C}$ together with an invertible 2-cell

$$\begin{array}{ccc}
XX & \xrightarrow{ff} & YY \\
\downarrow \alpha & & \downarrow \beta \\
X & \xrightarrow{f} & Y
\end{array}$$

such that this cube commutes:

$$XXX \alpha_{XX} \tilde{A} \alpha_{XX} = XXX \beta_{YY} \tilde{B} \beta_{YY}$$

When $\beta$ is an equi-arrow, the cube equation is equivalent to the simpler equa-
tion:

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
XX \xrightarrow{\alpha} \alpha X \xrightarrow{f f} Y Y
\end{array}
\end{array}
\end{array}
\end{array}
\]

which will be useful.

2.5. SEMI-MONOID TRANSFORMATIONS. A semi-monoid transformation between two parallel semi-monoid maps \((f, F)\) and \((g, G)\) is a 2-cell \(T : f \Rightarrow g\) in \(\mathcal{C}\) such that this cylinder commutes:

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
XX \xrightarrow{\alpha} \alpha X \xrightarrow{f f} Y Y
\end{array}
\end{array}
\end{array}
\end{array}
\]

2.6 LEMMA. Let \(f : X \to Y\) be a semi-monoid map. If \(f\) is an equi-arrow (as an arrow in \(\mathcal{C}\)) with quasi-inverse \(g : Y \to X\), then there is a canonical 2-cell \(G\) such that \((g, G)\) is a semi-monoid map.

Proof. The 2-cell \(G\) is defined as the mate [6] of the 2-cell \(F^{-1}\). It is routine to check the cube equation in 2.4. \(\square\)

2.7. PSEUDO-IDEMPOTENTS. A pseudo-idempotent is a pair \((I, \alpha)\) where \(\alpha : II \to I\) is an equi-arrow. A morphism of pseudo-idempotents from \((I, \alpha)\) to \((J, \beta)\) is a pair \((u, U)\) consisting of an arrow \(u : I \to J\) in \(\mathcal{C}\) and an invertible 2-cell

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
II \xrightarrow{u} JJ
\end{array}
\end{array}
\end{array}
\end{array}
\]

If \((u, U)\) and \((v, V)\) are morphisms of pseudo-idempotents from \((I, \alpha)\) to \((J, \beta)\), a 2-morphism of pseudo-idempotents from \((u, U)\) to \((v, V)\) is a 2-cell \(T : u \Rightarrow v\) satisfying the cylinder equation of 2.5.
2.8. Cancellable objects. An object \( I \) in \( \mathcal{C} \) is called cancellable if the two 2-functors \( \mathcal{C} \to \mathcal{C} \)

\[
X \mapsto IX \\
X \mapsto XI
\]

are fully faithful. (Fully faithful means that the induced functors on hom categories are equivalences.) A cancellable morphism between cancellable objects \( I \) and \( J \) is an equi-arrow \( u : I \to J \). (Equivalently it is an arrow such that the functors on hom cats defined by tensoring with \( u \) on either side are equivalences, cf. 5.1.) A cancellable 2-morphism between cancellable arrows is any invertible 2-cell.

We are now ready for the main definition and the main results.

2.9. Units. A unit object is by definition a cancellable pseudo-idempotent. Hence it is a pair \( (I, \alpha) \) consisting of an object \( I \) and an equi-arrow \( \alpha : II \to I \), with the property that tensoring with \( I \) from either side define fully faithful 2-functors \( \mathcal{C} \to \mathcal{C} \).

A morphism of units is a cancellable morphism of pseudo-idempotents. In other words, a unit morphism from \( (I, \alpha) \) to \( (J, \beta) \) is a pair \( (u, U) \) where \( u : I \to J \) is an equi-arrow and \( U \) is an invertible 2-cell

\[
\begin{array}{ccc}
II & \xrightarrow{uu} & JJ \\
\downarrow \alpha & & \downarrow \beta \\
I & \xrightarrow{u} & J.
\end{array}
\]

A 2-morphism of units is a cancellable 2-morphism of pseudo-idempotents. Hence a 2-morphism from \( (u, U) \) to \( (v, V) \) is an invertible 2-cell \( T : u \Rightarrow v \) such that

\[
\begin{array}{ccc}
II & \xrightarrow{uv} & JJ \\
\downarrow \alpha & & \downarrow \beta \\
I & \xrightarrow{u} & J
\end{array} = \begin{array}{ccc}
II & \xrightarrow{uv} & JJ \\
\downarrow \alpha & & \downarrow \beta \\
I & \xrightarrow{v} & J.
\end{array}
\]

This defines the 2-category of units.

In the next section we’ll see how the notion of unit object induces left and right constraints familiar from standard notions of monoidal 2-category. It will then turn out (Lemmas 5.1 and 5.2) that unit morphisms and 2-morphisms can be characterised as those morphisms and 2-morphisms compatible with the left and right constraints.
Theorem A (Associativity). Given a unit object \((I, \alpha)\), there is a canonical invertible 2-cell

\[
\begin{array}{c}
III \\
\downarrow_{I_{\alpha}} \\
II \\
\downarrow_{\alpha} \\
I \\
\end{array}
\]

which satisfies the pentagon equation

\[
\begin{array}{c}
\begin{array}{c}
III \\
\downarrow_{I_{\alpha}} \\
II \\
\downarrow_{\alpha} \\
I \\
\end{array}
\end{array}
\sim

\begin{array}{c}
\begin{array}{c}
III \\
\downarrow_{I_{\alpha}} \\
II \\
\downarrow_{\alpha} \\
I \\
\end{array}
\end{array}
\]

In other words, a unit object is automatically a semi-monoid. The 2-cell \(A\) is characterised uniquely in 3.7.

Theorem B. A unit morphism \((u, U) : (I, \alpha) \to (J, \beta)\) is automatically a semi-monoid map, when \(I\) and \(J\) are considered semi-monoids in virtue of Theorem A.

Theorem C (Contractibility). The 2-category of units in \(\mathcal{C}\) is contractible, if non-empty.

In other words, between any two units there exists a unit morphism, and between any two parallel unit morphisms there is a unique unit 2-morphism. Theorem C shows that units objects are unique up to homotopy, so in this sense ‘being unital’ is a property not a structure.

The proofs of these three theorems rely on the auxiliary structure of left and right constraints which we develop in the next section, and which also displays the relation with the classical notion of monoidal 2-category: in Section 7 we show that the cancellable-idempotent notion of unit is equivalent to the notion extracted from the definition of tricategory of Gordon, Power, and Street [2]. This is our Theorem E.

3 Left and right actions, and associativity of the unit (Theorem A)

Throughout this section we fix a unit object \((I, \alpha)\).
3.1 Lemma. For each object $X$ there exists pairs $(\lambda_X, L_X)$ and $(\rho_X, R_X)$,

$$\begin{align*}
\lambda_X : IX \to X, & \quad L_X : I\lambda_X \Rightarrow \alpha X \\
\rho_X : XI \to X, & \quad R_X : X\alpha \Rightarrow \rho_X I
\end{align*}$$

where $\lambda_X$ and $\rho_X$ are equi-arrows, and $L_X$ are $R_X$ are invertible 2-cells.

For every such family, there is a unique way to assemble the $\lambda_X$ into a natural transformation (this involves defining 2-cells $\lambda_f$ for every arrow $f$ in $\mathcal{C}$) in such a way that $L$ is a natural modification. Similarly for the $\rho_X$ and $R_X$.

The $\lambda_X$ is an action of $I$ on each $X$, and the 2-cell $L_X$ expresses an associativity constraint on this action. Using these structures we will construct the associator for $\alpha$, and show it satisfies the pentagon equation. Once that is in place we will see that the actions $\lambda$ and $\rho$ are coherent too (satisfying the appropriate pentagon equations).

We shall treat the left action. The right action is of course equivalent to establish.

3.2. Construction of the left action. Since tensoring with $I$ is a fully faithful 2-functor, the functor

$$\text{Hom}(IX, X) \to \text{Hom}(IIX, IX)$$

is an equivalence of categories. In the second category there is the canonical object $\alpha X$. Hence there is a pseudo pre-image which we denote $\lambda_X : IX \to X$, together with an invertible 2-cell $L_X : I\lambda_X \Rightarrow \alpha X$:

$$\begin{array}{ccc}
IIX & \xrightarrow{I\lambda_X} & IX \\
\alpha X & \downarrow{L_X} & \\
IX & \xrightarrow{\lambda_X} & IX
\end{array}$$

Since $\alpha$ is an equi-arrow, also $\alpha X$ is equi, and since $L_X$ is invertible, we conclude that also $I\lambda_X$ is an equi-arrow. Finally since the 2-functor ‘tensoring with $I$’ is fully faithful, it reflects equi-arrows, so already $\lambda_X$ is an equi-arrow.

3.3. Naturality. A slight variation in the formulation of the construction gives directly a natural transformation $\Lambda$ and a modification $L$: Let $L : \mathcal{C} \to \mathcal{C}$ denote the 2-functor ‘tensoring with $I$ on the left’. Since $L$ is fully faithful, there is an equivalence of categories

$$\text{Nat}(L, \text{Id}_{\mathcal{C}}) \to \text{Nat}(L \circ L, L).$$

Now in the second category we have the canonical natural transformation whose $X$-component is $\alpha X$ (and with trivial components on arrows). Hence there is a pseudo pre-image natural transformation $\lambda : L \to \text{Id}_{\mathcal{C}}$, together with a modification $L$ whose $X$-component is $L_X : I\lambda_X \Rightarrow \alpha X$. 

Documenta Mathematica 18 (2013) 71–110
Coherence for Weak Units

However, we wish to stress the fact that the construction is completely object-wise. This fact is of course due to the presence of the isomorphism \( L_X \): something isomorphic to a natural transformation is again natural. More precisely, to provide the 2-cell data \( \lambda_f \) needed to make \( \lambda \) into a natural transformation, just pull back the 2-cell data from the natural transformation \( \alpha X \). In detail, we need invertible 2-cells

\[
\begin{array}{ccc}
IX & \xrightarrow{\lambda_X} & X \\
\downarrow \scriptstyle{f} & & \downarrow \scriptstyle{f} \\
IY & \xrightarrow{\lambda_Y} & Y
\end{array}
\]

(Here the commutative cell is actually the 2-cell part of the natural transformation \( \alpha X \).) Now the point is that each 2-cell \( \lambda_f \) is uniquely defined by this compatibility: indeed, since the other three 2-cells in the diagram are invertible, there is a unique 2-cell that can fill the place of \( I\lambda_f \), and since \( I \) is cancellable this 2-cell comes from a unique 2-cell \( \lambda_f \). The required compatibilities of \( \lambda_f \) with composition, identities, and 2-cells now follows from its construction: \( \lambda_f \) is just the translation via \( L \) of the identity 2-cell \( \alpha X \).

3.4. Uniqueness of the left constraints. There may be many choices for \( \lambda_X \), and even for a fixed \( \lambda_X \), there may be many choices for \( L_X \). However, between any two pairs \( (\lambda_X, L_X) \) and \( (\lambda'_X, L'_X) \) there is a unique invertible 2-cell \( U_X^{\alpha} : \lambda_X \Rightarrow \lambda'_X \) such that this compatibility holds:

\[
\begin{array}{ccc}
I\lambda_X & \xrightarrow{U_X^{\alpha}} & I\lambda'_X \\
\downarrow \scriptstyle{I} & & \downarrow \scriptstyle{I} \\
L_X & \xrightarrow{\alpha X} & L'_X
\end{array}
\]

(Here the commutative cell is actually the 2-cell part of the natural transformation \( \alpha X \).) Now the point is that each 2-cell \( \lambda_f \) is uniquely defined by this compatibility: indeed, since the other three 2-cells in the diagram are invertible, there is a unique 2-cell that can fill the place of \( I\lambda_f \), and since \( I \) is cancellable this 2-cell comes from a unique 2-cell \( \lambda_f \). The required compatibilities of \( \lambda_f \) with composition, identities, and 2-cells now follows from its construction: \( \lambda_f \) is just the translation via \( L \) of the identity 2-cell \( \alpha X \).

...
There is of course a completely analogous statement for right constraints.

3.5. Construction of the associator. We define $A : I\alpha \Rightarrow \alpha I$ as the unique 2-cell satisfying the equation

$$ III = RI^{II-1}_1 III $$

with $I\alpha I$. This definition is meaningful: since $I\alpha I$ is an equi-arrow, pre-composing with $I\alpha I$ is a 2-equivalence, hence gives a bijection on the level of 2-cells, so $A$ is determined by the right-hand side of the equation. Note that $A$ is invertible since all the 2-cells in the construction are.

The associator $\tilde{A}$ is defined as $A$-followed-by-$\alpha$:

$$ \tilde{A} := A \#_I \alpha, $$

but it will be more convenient to work with $A$.

3.6 Proposition. The definition of $A$ does not depend on the choices of left constraint $(\lambda, L)$ and right constraint $(\rho, R)$.

Proof. Write down the right-hand side of (9) in terms of different left and right constraints. Express these cells in terms of the original $L_I$ and $R_I$, using the comparison 2-cells $U^\text{left}_I$ and $U^\text{right}_I$ of 3.4. Finally observe that these comparison cells can be moved across the commutative square to cancel each other pairwise. $\square$
3.7. Uniqueness of $A$. Equation (9) may not appear familiar, but it is equivalent to the following ‘pentagon’ equation (after post-whiskering with $\alpha$): 

$$III \xrightarrow{\rho I} III \xrightarrow{\lambda \# \alpha} II = III \xrightarrow{\rho I} III \xrightarrow{\lambda \# \alpha} II$$

From this pentagon equation we shall derive the pentagon equation for $A$, asserted in Theorem A. To this end we need comparison between $\alpha$, $\lambda_I$, and $\rho_I$, which we now establish, in analogy with Axiom (1) of monoidal category: the left and right constraints coincide on the unit object, up to a canonical 2-cell:

3.8 Lemma. There are unique invertible 2-cells

$$\rho_I \xRightarrow{E} \alpha \xRightarrow{D} \lambda_I,$$

such that

$$III \xrightarrow{I\lambda} II = III \xrightarrow{\alpha I} II = III \xrightarrow{E I} II$$

Proof. The left-hand equation defines uniquely a 2-cell $I\alpha \Rightarrow I\lambda_I$, and since $I$ is cancellable, this cell comes from a unique 2-cell $\alpha \Rightarrow \lambda_I$ which we then call D. Same argument for E. \hfill $\square$

**Theorem A (Associativity).** Given a unit object $(I, \alpha)$, there is a canonical invertible 2-cell

$$III \xrightarrow{\alpha I} II$$

which satisfies the pentagon Equation (8).
Proof. On each side of the cube equation (10), paste the cell $EII$ on the top, and the cell $IID$ on the left. On the left-hand side of the equation we can use Equations (11) directly, while on the right-hand side we first need to move those cells across the commutative square before applying (11). The result is precisely the pentagon cube for $\tilde{A} = A \# \alpha$. 

3.9. Coherence of the actions. We have now established that $(I, \alpha, \tilde{A})$ is a semi-monoid, and may observe that the left and right constraints are coherent actions, i.e. that their ‘associators’ $L$ and $R$ satisfy the appropriate pentagon equations. For the left action this equation is:

Establishing this (and the analogous equation for the right action) is a routine calculation which we omit since we will not actually need the result. We also note that the two actions are compatible—i.e. constitute a two-sided action. Precisely this means that there is a canonical invertible 2-cell

\[
IXI \xrightarrow{\lambda \# I} XI
\]

This 2-cell satisfies two pentagon equations, one for $IIXI$ and one for $IXII$.

4 Units in the 2-category of arrows in $\mathscr{C}$, and Theorem B

In this section we prove Theorem B, which asserts that a morphism of units $(u, U) : (I, \alpha) \to (J, \beta)$ is automatically a semi-monoid map (with respect to the canonical associators $A$ and $B$ of the two units). We have to establish the cube equation of 2.4, or in fact the reduced version (7). The strategy to establish Equation (7) is to interpret everything in the 2-category of arrows of $\mathscr{C}$. The key point is to prove that a morphism of units is itself a unit in the 2-category of arrows. Then we invoke Theorem A to get an associator for this unit, and a pentagon equation, whose short form (6) will be the sought equation.
4.1. The 2-category of arrows. The 2-category of arrows in $\mathcal{C}$, denoted $\mathcal{C}^2$, is the 2-category described as follows. The objects of $\mathcal{C}^2$ are the arrows of $\mathcal{C}$,

$$X_0 \xrightarrow{x} X_1.$$ 

The arrows from $(X_0, X_1, x)$ to $(Y_0, Y_1, y)$ are triples $(f_0, f_1, F)$ where $f_0 : X_0 \to Y_0$ and $f_1 : X_1 \to Y_1$ are arrows in $\mathcal{C}$ and $F$ is a 2-cell

$$
\begin{array}{c}
X_0 \xrightarrow{f_0} Y_0 \\
X_1 \xrightarrow{f_1} Y_1.
\end{array}
$$

If $(g_0, g_1, G)$ is another arrow from $(X_0, X_1, x)$ to $(Y_0, Y_1, y)$, a 2-cell from $(f_0, f_1, F)$ to $(g_0, g_1, G)$ is given by a pair $(m_0, m_1)$ where $m_0 : f_0 \Rightarrow g_0$ and $m_1 : f_1 \Rightarrow g_1$ are 2-cells in $\mathcal{C}$ compatible with $F$ and $G$ in the sense that this cylinder commutes:

$$
\begin{array}{c}
X_0 \xleftarrow{m_0} Y_0 \\
X_1 \xleftarrow{f_1} Y_1.
\end{array}
$$

Composition of arrows in $\mathcal{C}^2$ is just pasting of squares. Vertical composition of 2-cells is just vertical composition of the components (the compatibility is guaranteed by pasting of cylinders along squares), and horizontal composition of 2-cells is horizontal composition of the components (compatibility guaranteed by pasting along the straight sides of the cylinders). Note that $\mathcal{C}^2$ inherits a tensor product from $\mathcal{C}$: this follows from functoriality of the tensor product on $\mathcal{C}$.

4.2 Lemma. If $I_0$ and $I_1$ are cancellable objects in $\mathcal{C}$ and $i : I_0 \to I_1$ is an equi-arrow, then $i$ is cancellable in $\mathcal{C}^2$.

Proof. We have to show that for given arrows $x : X_0 \to X_1$ and $y : Y_0 \to Y_1$, the functor

$$\text{Hom}_{\mathcal{C}^2}(x, y) \to \text{Hom}_{\mathcal{C}^2}(ix, iy)$$

defined by tensoring with $i$ on the left is an equivalence of categories (the check for tensoring on the right is analogous).
Let us first show that this functor is essentially surjective. Let

\[
\begin{array}{ccc}
I_0 X_0 & \xrightarrow{s_0} & I_0 Y_0 \\
ix \downarrow & S & iy \\
I_1 X_1 & \xrightarrow{s_1} & I_1 Y_1
\end{array}
\]

be an object in \(\text{Hom}_{\mathcal{C}_2}(ix, iy)\). We need to find a square

\[
\begin{array}{ccc}
X_0 & \xrightarrow{k_0} & Y_0 \\
x \downarrow & K & y \\
X_1 & \xrightarrow{k_1} & Y_1
\end{array}
\]

and an isomorphism \((m_0, m_1)\) from \((s_0, s_1, S)\) to \((I_0 k_0, I_1 k_1, iK)\), i.e. a cylinder

\[
\begin{array}{ccc}
I_0 X_0 & \xrightarrow{m_0} & I_0 Y_0 \\
ix \downarrow & S & iy \\
I_1 X_1 & \xrightarrow{s_1} & I_1 Y_1
\end{array} \quad \begin{array}{ccc}
I_0 X_0 & \xrightarrow{m_1} & I_1 Y_1 \\
ix \downarrow & S & iy \\
I_1 X_1 & \xrightarrow{s_1} & I_1 Y_1
\end{array}
\]

Since \(I_0\) is a cancellable object, the arrow \(s_0\) is isomorphic to \(I_0 k_0\) for some \(k_0 : X_0 \rightarrow Y_0\). Let the connecting invertible 2-cell be denoted \(m_0 : s_0 \Rightarrow I_0 k_0\). Similarly we find \(k_1\) and \(m_1 : s_1 \Rightarrow I_1 k_1\). Since \(m_0\) and \(m_1\) are invertible, there is a unique 2-cell

\[
\begin{array}{ccc}
I_0 X_0 & \xrightarrow{i k_0} & I_0 Y_0 \\
ix \downarrow & T & iy \\
I_1 X_1 & \xrightarrow{i k_1} & I_1 Y_1
\end{array}
\]

that can take the place of \(iK\) in the cylinder equation; it remains to see that \(T\) is of the form \(iK\) for some \(K\). But this follows since the map

\[
2\text{Cell}_{\mathcal{C}_2}(k_0 \# y, x \# k_1) \rightarrow 2\text{Cell}_{\mathcal{C}_2}(i(k_0 \# y), i(x \# k_1))
\]

\[
K \mapsto iK
\]

is a bijection. Indeed, the map factors as ‘tensoring with \(I_0\) on the left’ followed by ‘post-composing with \(iY_1\’; the first is a bijection since \(I_0\) is cancellable, the second is a bijection since \(i\) (and hence \(iY_1\) is an equi-arrow).
Now for the fully faithfulness of \( \text{Hom}_{\mathcal{C}^2}(x, y) \to \text{Hom}_{\mathcal{C}^2}(ix, iy) \). Fix two objects in the left-hand category, \( P \) and \( Q \):

\[
\begin{array}{ccc}
X_0 & \xrightarrow{p_0} & Y_0 \\
\downarrow x & & \downarrow y \\
X_1 & \xrightarrow{p_1} & Y_1 \\
\end{array}
\quad
\quad
\begin{array}{ccc}
X_0 & \xrightarrow{q_0} & Y_0 \\
\downarrow x & & \downarrow y \\
X_1 & \xrightarrow{q_1} & Y_1 \\
\end{array}
\]

The arrows from \( P \) to \( Q \) are pairs \((m_0, m_1)\) consisting of

\[
m_0 : p_0 \Rightarrow q_0 \quad m_1 : p_1 \Rightarrow q_1
\]

cylinder-compatible with the 2-cells \( P \) and \( Q \). The image of these two objects are

\[
\begin{array}{ccc}
I_0X_0 & \xrightarrow{I_0p_0} & I_0Y_0 \\
\downarrow ix & & \downarrow iy \\
I_1X_1 & \xrightarrow{I_1p_1} & I_1Y_1 \\
\end{array}
\quad
\begin{array}{ccc}
I_0X_0 & \xrightarrow{I_0q_0} & I_0Y_0 \\
\downarrow ix & & \downarrow iy \\
I_1X_1 & \xrightarrow{I_1q_1} & I_1Y_1 \\
\end{array}
\]

The possible 2-cells from \( iP \) to \( iQ \) are pairs \((n_0, n_1)\) consisting of

\[
n_0 : I_0p_0 \Rightarrow I_0q_0 \quad n_1 : I_1p_1 \Rightarrow I_1q_1
\]

cylinder-compatible with the 2-cells \( iP \) and \( iQ \). Now since \( I_0 \) is cancellable, every 2-cell \( n_0 \) like this is uniquely of the form \( I_0n_0 \) for some \( n_0 \). Hence there is a bijection between the possible \( m_0 \) and the possible \( n_0 \). Similarly for \( m_1 \) and \( n_1 \). So there is a bijection between pairs \((m_0, m_1)\) and pairs \((n_0, n_1)\).

Now by functoriality of tensoring with \( i \), all images of compatible \((m_0, m_1)\) are again compatible. It remains to rule out the possibility that some \((n_0, n_1)\) pair could be compatible without \((m_0, m_1)\) being so, but this follows again from the argument that ‘tensoring with \( i \) on the left’ is a bijection on hom sets, just like argued for (12).

4.3 LEMMA. An arrow in \( \mathcal{C}^2 \),

\[
\begin{array}{ccc}
X_0 & \xrightarrow{f_0} & Y_0 \\
\downarrow x & & \downarrow y \\
X_1 & \xrightarrow{f_1} & Y_1 \\
\end{array}
\]

is an equi-arrow in \( \mathcal{C}^2 \) if the components \( f_0 \) and \( f_1 \) are equi-arrows in \( \mathcal{C} \) and \( F \) is invertible.
Proof. We can construct an explicit quasi-inverse by choosing quasi-inverses to the components.

4.4 Corollary. If \((I_0, \alpha_0)\) and \((I_1, \alpha_1)\) are units in \(\mathcal{C}\), and \((u, U) : I_0 \to I_1\) is a unit map between them, then

\[ u : I_0 \to I_1 \]

is a unit object in \(\mathcal{C}^2\) with structure map

\[
\begin{array}{ccc}
I_0 I_0 & \xrightarrow{\alpha_0} & I_0 \\
\downarrow{uu} & & \downarrow{u} \\
I_1 I_1 & \xrightarrow{\alpha_1} & I_1 \\
\end{array}
\]

Proof. The object \(u\) is cancellable by Lemma 4.2, and the morphism \((\alpha_0, \alpha_1, U^{-1})\) from \(uu\) to \(u\) is an equi-arrow by Lemma 4.3.

Theorem B. Let \((I_0, \alpha_0)\) and \((I_1, \alpha_1)\) be units, with canonical associators \(A_0\) and \(A_1\), respectively. If \((u, U)\) is a unit map from \(I_0\) to \(I_1\) then it is automatically a semi-monoid map. That is,

\[
\begin{array}{ccc}
I_0 I_0 I_0 & \xrightarrow{uuu} & I_1 I_1 I_1 \\
\downarrow{I_0 \alpha_0} & & \downarrow{\alpha_1 I_1} \\
I_0 I_0 & \xrightarrow{uu} & I_1 I_1 \\
\end{array} = \begin{array}{ccc}
I_0 I_0 I_0 & \xrightarrow{uuu} & I_1 I_1 I_1 \\
\downarrow{uU} & & \downarrow{\alpha_1 I_1} \\
I_0 I_0 & \xrightarrow{uu} & I_1 I_1 \\
\end{array}
\]

Proof. By the previous Corollary, \((u, U^{-1})\) is a unit object in \(\mathcal{C}^2\). Hence there is a canonical associator

\[ B : uU^{-1} \leftrightarrow U^{-1}u. \]

By definition of 2-cells in \(\mathcal{C}^2\), this is a pair of 2-cells in \(\mathcal{C}\)

\[ B_0 : I_0 \alpha_0 \Rightarrow \alpha_0 I_0 \quad B_1 : I_1 \alpha_1 \Rightarrow \alpha_1 I_1, \]

fitting the cylinder equation

\[
\begin{array}{ccc}
I_0 I_0 I_0 & \xrightarrow{\alpha_0 I_0} & I_0 I_0 \\
\downarrow{uu} & & \downarrow{uu} \\
I_1 I_1 I_1 & \xrightarrow{I_0 \alpha_0} & I_0 I_0 \\
\end{array} = \begin{array}{ccc}
I_0 I_0 I_0 & \xrightarrow{\alpha_0 I_0} & I_0 I_0 \\
\downarrow{uU^{-1}} & & \downarrow{uu} \\
I_1 I_1 I_1 & \xrightarrow{\alpha_1 I_1} & I_1 I_1 \\
\end{array}
\]
This is precisely the cylinder diagram we are looking for—provided we can show that $B_0 = A_0$ and $B_1 = A_1$. But this is a consequence of the characterising property of the associator of a unit: first note that as a unit object in $\mathcal{C}^2$, $u$ induces left and right constraints: for each object $x : X_0 \to X_1$ in $\mathcal{C}^2$ there is a left action of the unit $u$, and this left action will induce a left action of $(I_0, \alpha_0)$ on $X_0$ and a left action of $(I_1, \alpha_1)$ on $X_1$ (the ends of the cylinders). Similarly there is a right action of $u$ which induces right actions at the ends of the cylinder. Now the unique $B$ that exists as associator for the unit object $u$ compatible with the left and right constraints induces $B_0$ and $B_1$ at the ends of the cylinder, and these will of course be compatible with the induced left and right constraints. Hence, by uniqueness of associators compatible with left and right constraints, these induced associators $B_0$ and $B_1$ must coincide with $A_0$ and $A_1$. Note that this does not dependent on choice of left and right constraints, cf. Proposition 3.6.

\[ \square \]

5 Contractibility of the space of weak units (Theorem C)

The goal of this section is to prove Theorem C, which asserts that the 2-category of units in $\mathcal{C}$ is contractible if non-empty. First we describe the unit morphisms and unit 2-morphisms in terms of compatibility with left and right constraints. This will show that there are not too many 2-cells. Second we use the left and right constraints to connect any two units.

The following lemma shows that just as the single arrow $\alpha$ induces all the $\lambda_X$ and $\rho_X$, the single 2-cell $U$ of a unit map induces families $U^\text{left}_X$ and $U^\text{right}_X$ expressing compatibility with $\lambda_X$ and $\rho_X$.

5.1 Lemma. Let $(I, \alpha)$ and $(J, \beta)$ be units, and let $(u, U)$ be a morphism of pseudo-idempotents from $(I, \alpha)$ to $(J, \beta)$. The following are equivalent.

(i) $u$ is an equi-arrow (i.e. $u$ is a morphism of units).

(ii) $u$ is left cancellable, i.e. tensoring with $u$ on the left is an equivalence of categories $\text{Hom}(X, Y) \to \text{Hom}(IX, JY)$.

(ii') $u$ is right cancellable, i.e. tensoring with $u$ on the right is an equivalence of categories $\text{Hom}(X, Y) \to \text{Hom}(XI, YJ)$.

(iii) For fixed left actions $(\lambda_X, L_X)$ for the unit $(I, \alpha)$ and $(\ell_X, L'_X)$ for the unit $(J, \beta)$, there is a unique invertible 2-cell $U^\text{left}_X$, natural in $X$:

\[
\begin{array}{ccc}
IX & \xrightarrow{u_X} & JX \\
\lambda_X & & \ell_X \\
X & \xrightarrow{U^\text{left}_X} & X
\end{array}
\]
such that this compatibility holds:

\[
\begin{array}{cccccc}
II X & \xrightarrow{\ u u X \ } & JJ X \\
I \lambda_X & \circ & \alpha_X & \circ & U_X & \beta_X & = & I \lambda_X & \circ & u U_X^{\text{left}} & \circ & J \ell_X & \circ & L_X' & \beta_X \\
IX & \xrightarrow{u_X} & JX \\
\end{array}
\]

(iii') For fixed right actions \((\rho_X, R_X)\) for the unit \((I, \alpha)\) and \((r_X, R'_X)\) for the unit \((J, \beta)\), there is a unique invertible 2-cell \(U_X^{\text{right}}\), natural in \(X\):

\[
\begin{array}{cccc}
XI & \xrightarrow{X u} & X J \\
\rho_X & \circ & U_X^{\text{right}} & \circ & r_X \\
X & \xrightarrow{X u} & X J \\
\end{array}
\]

such that this compatibility holds:

\[
\begin{array}{cccccc}
XII & \xrightarrow{X u u} & X J J \\
X \alpha & \circ & R_X & \circ & U_X^{\text{right}} & \circ & r_X J \\
XI & \xrightarrow{X u} & X J \\
\end{array}
\]

\[
\begin{array}{cccccc}
XII & \xrightarrow{X u u} & X J J \\
X \beta & \circ & R'_X & \circ & r_X J \\
XI & \xrightarrow{X u} & X J \\
\end{array}
\]

Proof. (i) implies (ii): ‘tensoring with \(u\)’ can be done in two steps: given an arrow \(X \rightarrow Y\), first tensor with \(I\) to get \(IX \rightarrow IY\), and then post-compose with \(uY\) to get \(IX \rightarrow JY\). The first step is an equivalence because \(I\) is a unit, and the second step is an equivalence because \(u\) is an equi-arrow.

(ii) implies (iii): In Equation (13), the 2-cell labelled \(u U_X^{\text{left}}\) is uniquely defined by the three other cells, and it is invertible since the three other cells are. Since tensoring with \(u\) on the left is an equivalence, this cell comes from a unique invertible cell \(U_X^{\text{right}}\), justifying the label \(u U_X^{\text{right}}\).

(iii) implies (i): The invertible 2-cell \(U_X^{\text{right}}\) shows that \(uX\) is isomorphic to an equi-arrow, and hence is an equi-arrow itself. Now take \(X\) to be a right cancellable object (like for example \(I\)) and conclude that already \(u\) is an equi-arrow.

Finally, the equivalence \((i) \Rightarrow (ii') \Rightarrow (iii') \Rightarrow (i)\) is completely analogous. \(\square\)

Note that for \((u, U)\) the identity morphism on \((I, \alpha)\), we recover Observation 3.4.
5.2 Lemma. Let \((I, \alpha)\) and \((J, \beta)\) be units; let \((u, U)\) and \((v, V)\) be morphisms of pseudo-idempotents from \(I\) to \(J\); and consider a 2-cell \(T : u \Rightarrow v\). Then the following are equivalent.

(i) \(T\) is an invertible 2-morphism of pseudo-idempotents.

(ii) \(T\) is a left cancellable 2-morphism of pseudo-idempotents (i.e., induces a bijection on hom sets (of hom cats) by tensoring with \(T\) from the left).

(ii') \(T\) is a right cancellable 2-morphism of pseudo-idempotents (i.e., induces a bijection on hom sets (of hom cats) by tensoring with \(T\) from the right).

(iii) For fixed left actions \((\lambda_X, L_X)\) for \((I, \alpha)\) and \((\ell_X, L'_X)\) for \((J, \beta)\), with induced canonical 2-cells \(U_X^{\text{left}}\) and \(V_X^{\text{left}}\) as in 5.1, we have:

\[
\begin{align*}
IX & \xrightarrow{\lambda_X} X \\
TX & \xrightarrow{\ell_X} X \\
IX & \xrightarrow{v_X} JX \\
U_X^{\text{left}} & \xrightarrow{X} X \\
X & \xrightarrow{\circ} X
\end{align*}
\]

\[
(15)
\]

(iii') For fixed right actions \((\rho_X, R_X)\) for \((I, \alpha)\) and \((r_X, R'_X)\) for \((J, \beta)\), with induced canonical 2-cells \(U_X^{\text{right}}\) and \(V_X^{\text{right}}\) as in 5.1, we have:

\[
\begin{align*}
XI & \xrightarrow{\rho_X} X \\
XT & \xrightarrow{Xu} X \\
XI & \xrightarrow{xv} X \\
U_X^{\text{right}} & \xrightarrow{X} X \\
X & \xrightarrow{\circ} X
\end{align*}
\]

\[
(16)
\]

Proof. It is obvious that (i) implies (ii). Let us prove that (iii) implies (iii'), so assume that tensoring with \(T\) on the left defines a bijection on the level of 2-cells. Start with the cylinder diagram for compatibility of tensor 2-cells.
(cf. 2.5). Tensor this diagram with $X$ on the right to get

\[
\begin{align*}
&\begin{array}{ccc}
&I \quad II \quad X^v \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array}
\begin{array}{ccc}
&V \quad \downarrow uX \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array}
= \\
\begin{array}{ccc}
&\downarrow \alpha X \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array}
\end{align*}
\]

On each side of this equation, paste an $L_X$ along $\alpha X$, apply Equation (13) on each side, and cancel the $L'_X$ that appear on the other side of the square. The resulting diagram

\[
\begin{align*}
&\begin{array}{ccc}
&I \quad II \quad X^v \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array}
\begin{array}{ccc}
&\downarrow \alpha X \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array} = \\
\begin{array}{ccc}
&\downarrow \alpha X \\
\downarrow \alpha X & & \downarrow \beta X \\
IX & & JX
\end{array}
\end{align*}
\]

is the tensor product of $T$ with the promised equation (15). Since $T$ is cancellable, we can cancel it away to finish.

(iii) implies (i): the arguments in (ii)$\Rightarrow$(iii) can be reversed: start with (15), tensor with $T$ on the left, and apply (13) to arrive at the axiom for being a 2-morphism of pseudo-idempotents. Since both $U^\text{left}_X$ and $V^\text{right}_X$ are invertible, so is $TX$. Now take $X$ to be a right cancellable object, and cancel it away to conclude that already $T$ is invertible.

Finally, the equivalence (i)$\Rightarrow$(ii)$'\Rightarrow$(iii)$'$ implies (i) is completely analogous. □

5.3 Corollary. Given two parallel morphisms of units, there is a unique unit 2-morphism between them.

Proof. Choose left actions for $(I, \alpha)$ and $(J, \beta)$ as in Lemma 5.2 (iii), and take $X$ to be a right cancellable object. For given morphisms of units $u$ and $v$ as in Lemma 5.2, Equation (15) defines the 2-cell $T$ uniquely, since $\lambda_X$ is an equi-arrow and $X$ is right cancellable. □

Next we aim at proving that there is a unit morphism between any two units. The strategy is to use the left and right constraints to produce a unit morphism

\[
I \longrightarrow IJ \longrightarrow J.
\]

As a first step towards this goal we have:
5.4 Lemma. Let $I$ and $J$ be units, and pick a left constraint $\lambda$ for $I$ and a right constraint $r$ for $J$. Put

$$\gamma := r_I \lambda_J : IJJ \to IJ$$

Then $(IJ, \gamma)$ is a unit.

Proof. Since $I$ and $J$ are cancellable, clearly $IJ$ is cancellable too. Since $\lambda_J$ and $r_I$ are equi-arrows, $\gamma$ is too. \hfill $\square$

5.5 Lemma. There is an invertible 2-cell

$$\begin{array}{c}
IJJIJ \\
\downarrow \gamma \\
IJJ \\
\downarrow \lambda_J \\
IJ \\
\end{array} \xrightarrow{Z} \begin{array}{c}
JJ \\
\downarrow \beta \\
J. \\
\end{array}$$

Hence $(\lambda_J, Z)$ is a unit map. (And there is another 2-cell making $r_I$ a unit map.)

Proof. The 2-cell $Z$ is defined like this:

where the 2-cell $K^\lambda$ is constructed in Lemma 7.2. \hfill $\square$

5.6 Corollary. Given two units, there exists a unit morphism between them.

Proof. Continuing the notation from above, by Lemma 5.4, $(IJ, \gamma)$ is a unit, and by Lemma 5.5, $\lambda : IJ \to J$ is a morphism of units. Similarly, $r : IJ \to I$ is a unit morphism, and by Lemma 2.6 any chosen pseudo-inverse $r^{-1} : I \to IJ$ is again a unit morphism. Finally we take

$$I \xrightarrow{r^{-1}} IJ \xrightarrow{\lambda} J.$$ 

\hfill $\square$
Theorem C (Contractibility). The 2-category of units in \( \mathcal{C} \) is contractible, if non-empty. In other words, between any two units there exists a unit morphism, and between any two parallel unit morphisms there is a unique unit 2-morphism.

Proof. By Lemma 5.6 there is a unit morphism between any two units (an equi-arrow by definition), and by Corollary 5.3 there is a unique unit 2-morphism between any two parallel unit morphisms.

\[ \square \]

6 Classical units

In this section we review the classical theory of units in a monoidal 2-category, as extracted from the definition of tricategory of Gordon, Power, and Street [2]. In the next section we compare this notion with the cancellable-idempotent approach of this work. The equivalence is stated explicitly in Theorem E.

6.1. Tricategories. The notion of tricategory introduced by Gordon, Power, and Street [2] is roughly a weak category structure enriched over bicategories: this means that the structure maps (composition and unit) are weak 2-functors satisfying weak versions of associativity and unit constraints. For the associativity, the pentagon equation is replaced by a specified pentagon 3-cell (TD7), required to satisfy an equation corresponding to the 3-dimensional associahedron. This equation (TA1) is called the nonabelian 4-cocycle condition. For the unit structure, three families of 3-cells are specified (TD8): one corresponding to the Kelly axiom, one left variant, and one right variant (those two being the higher-dimensional analogues of Axioms (2) and (3) of monoidal category). Two axioms are imposed on these three families of 3-cells: one (TA2) relating the left family with the middle family, and one (TA3) relating the right family with the middle family. These are called left and right normalisation. (These two axioms are the higher-dimensional analogues of the first argument in Kelly’s lemma 1.6.) It is pointed out in [2] that the middle family together with the axioms (TA2) and (TA3) completely determine the left and right families if they exist.

6.2. Monoidal 2-categories. By specialising the definition of tricategory to the one-object case, and requiring everything strict except the units, we arrive at the following notion of monoidal 2-category: a monoidal 2-category is a semi-monoidal 2-category (cf. 2.2) equipped with an object \( I \), two natural transformations \( \lambda \) and \( \rho \) with equi-arrow components

\[ \lambda_X : IX \to X \]

\[ \rho_X : XI \to X \]
and (invertible) 2-cell data

$$
\begin{array}{c}
IX \xrightarrow{\lambda_X} X \\
\downarrow{\lambda_f} \quad \downarrow{f} \\
IY \xrightarrow{\lambda_Y} Y
\end{array}
\quad
\begin{array}{c}
XI \xrightarrow{\rho_X} X \\
\downarrow{\rho_f} \quad \downarrow{f} \\
YI \xrightarrow{\rho_Y} Y,
\end{array}
$$

together with three natural modifications $K$, $K^\lambda$, and $K^\rho$, with invertible components

$$
K : X \lambda_Y \Rightarrow \rho_X Y \\
K^\lambda : \lambda_X Y \Rightarrow \lambda_X Y \\
K^\rho : X \rho_Y \Rightarrow \rho_{XY}.
$$

We call $K$ the Kelly cell.

These three families are subject to the following two equations:

$$
\begin{array}{c}
X\lambda_Y Z \xrightarrow{XK^\lambda_{Y,Z}} X\lambda_Y Z \\
\downarrow{\kappa_{X,Y,Z}} \quad \downarrow{\kappa_{X,Y,Z}} \\
\rho_X Y Z
\end{array}
$$

(17)

$$
\begin{array}{c}
X\rho_Y Z \xrightarrow{XK^\rho_{Y,Z}} \rho_{XY} Z \\
\downarrow{\kappa_{X,Y,Z}} \quad \downarrow{\kappa_{X,Y,Z}} \\
XY\lambda_Y Z
\end{array}
$$

(18)

6.3 Remark. We have made one change compared to [2], namely the direction of the arrow $\rho_X$: from the viewpoint of $\alpha$ it seems more practical to work with $\rho_X : XI \rightarrow X$ rather than with the convention of $\rho_X : X \rightarrow XI$ chosen in [2]. Since in any case it is an equi-arrow, the difference is not essential. (Gurski in his thesis [3] has studied a version of tricategory where all the equi-arrows in the definition are equipped with specified pseudo-inverses. This has the advantage that the definition becomes completely algebraic, in a technical sense.)

6.4 Lemma. The object $I$ is cancellable (independently of the existence of $K$, $K^\lambda$, and $K^\rho$.)

Proof. We need to establish that ‘tensoring with $I$ on the left’,

$$
L : \text{Hom}(X,Y) \rightarrow \text{Hom}(IX, IY),
$$
is an equivalence of categories. But this follows since the diagram

\[
\begin{array}{c}
\text{Hom}(X,Y) \xrightarrow{L} \text{Hom}(IX, IY) \\
\downarrow \quad \text{Id} \quad \downarrow \text{Id} \\
\text{Hom}(X,Y) \xrightarrow{\lambda_Y \#} \text{Hom}(IX, Y)
\end{array}
\]

is commutative up to isomorphism: the component at \( f : X \to Y \) of this isomorphism is just the naturality square \( \lambda_f \). Since the functors \( \lambda_X \# \) and \( \# \lambda_Y \) are equivalences, it follows from this isomorphism that \( L \) is too. \( \square \)

6.5. **Coherence of the Kelly cell.** As remarked in [2], if the \( K^\lambda \) and \( K^\rho \) exist, they are determined uniquely from \( K \) and the two axioms. Indeed, the two equations

\[
\begin{align*}
I\lambda_Y Z \xrightarrow{\rho_Y I} & I\lambda_Y Z \\
\kappa_{I,Y,Z} \xrightarrow{\rho_I Y Z} & \kappa_{I,Y,Z} \\
\rho_{I,Y Z} \xrightarrow{\rho_{I,Y Z}} & \rho_{I,Y Z}
\end{align*}
\]

\[
\begin{align*}
X\rho_Y I \xrightarrow{\rho_{XY I}} & \rho_{XY I} \\
X\kappa_{Y,I} \xrightarrow{X\kappa_{Y,I}} & X\kappa_{Y,I} \\
\rho_{XY I} \xrightarrow{X\rho_Y I} & \rho_{XY I}
\end{align*}
\]

which are just special cases of (17) and (18) uniquely determine \( K^\lambda \) and \( K^\rho \), by cancellability of \( I \). But these two special cases of the axioms do not imply the general case.

We shall take the Kelly cell \( K \) as the main structure, and say that \( K \) is *coherent on the left* (resp. *on the right*) if Axiom (17) (resp. (18)) holds for the induced cell \( K^\lambda \) (resp. \( K^\rho \)). We just say *coherent* if both hold. We shall see (7.8) that in fact coherence on the left implies coherence on the right and vice versa.

6.6. **Naturality.** The Kelly cell is a modification. For future reference we spell out the naturality condition satisfied: given arrows \( f : X \to X' \) and \( g : Y \to Y' \), we have

\[
\begin{align*}
X\lambda_Y \xrightarrow{f} & X\lambda_Y \\
\rho_{XY} \xrightarrow{f g} & \rho_{XY} \\
X'\lambda_Y \xrightarrow{f g} & X'\lambda_Y
\end{align*}
\]

\[
\begin{align*}
\rho_{XY} \xrightarrow{f g} & \rho_{XY} \\
\rho_{XY} \xrightarrow{f g} & \rho_{XY}
\end{align*}
\]
6.7 Remark. Particularly useful is naturality of $\lambda$ with respect to $\lambda_X$ and naturality of $\rho$ with respect to $\rho_X$. In these cases, since $\lambda_X$ and $\rho_X$ are equi-arrows, we can cancel them and find the following invertible 2-cells:

$$N^\lambda : I\lambda_X \Rightarrow \lambda_I$$

$$N^\rho : \rho_X I \Rightarrow X\rho_I,$$

in analogy with Observation (5) of monoidal categories.

The following lemma holds for $\mathbf{K}$ independently of Axioms (17) and (18):

6.8 Lemma. The Kelly cell $\mathbf{K}$ satisfies the equation

$$XIIY \xrightarrow{\rho_X IY} X\lambda_Y \Rightarrow X\lambda_Y = XIIY \xrightarrow{N^\rho IY} X\rho_Y \Rightarrow X\rho_Y \xrightarrow{N^\rho} \mathbf{K}$$

Proof. It is enough to establish this equation after post-whiskering with $X\lambda_Y$. The rest is a routine calculation, using on one side the definition of the cell $N^\lambda$, then naturality of $\mathbf{K}$ with respect to $f = X$ and $g = \lambda_Y$. On the other side, use the definition of $N^\rho$ and then naturality of $\mathbf{K}$ with respect to $f = \rho_X$ and $g = Y$. In the end, two $\mathbf{K}$-cells cancel.

Combining the 2-cells described so far we get

$$\rho_I I \xrightarrow{\mathbf{K}^{-1}} I\lambda_I \xrightarrow{\mathbf{N}^\lambda} \lambda_I I \Rightarrow \lambda_I I$$

and hence, by cancelling $I$ on the right, an invertible 2-cell

$$P : \rho_I \Rightarrow \lambda_I.$$

Now we could also define $Q : \rho_I \Rightarrow \lambda_I$ in terms of

$$I\rho_I \xrightarrow{\mathbf{K}^e} \rho_I I \xrightarrow{\mathbf{N}^e} \rho_I I \Rightarrow I\lambda_I.$$

Finally, in analogy with Axiom (1) for monoidal categories:

6.9 Lemma. We have $P = Q$. (This is true independently of Axioms (17) and (18).)

Proof. Since $I$ is cancellable, it is enough to show $IP = IQ$. To establish this equation, use the constructions of $P$ and $Q$, then substitute the characterising Equations (19) for the auxiliary cells $\mathbf{K}^\lambda$ and $\mathbf{K}^\rho$, and finally use Lemma 6.8. □
6.10. The 2-category of GPS units. For short, we shall say GPS unit for
the notion of unit just introduced. In summary, a GPS unit is a quadruple
\((I, \lambda, \rho, K)\) where \(I\) is an object, \(\lambda_X\) and \(\rho_X\) are natural
transformations with equi-arrow components, and \(K : X\lambda_Y \Rightarrow \rho_XY\) is
a coherent Kelly cell (natural in \(X\) and \(Y\), of course).

A morphism of GPS units from \((I, \lambda, \rho, K)\) to \((J, \ell, r, H)\) is an arrow \(u : I \rightarrow J\)
equipped with natural families of invertible 2-cells

\[
\begin{align*}
IX \xrightarrow{u_X} JX \\
\lambda_X & \downarrow \quad \Upsilon_{\lambda X}^\leftarrow \quad \ell_X \\
X & \xrightarrow{u} X
\end{align*}
\begin{align*}
XI \xrightarrow{\rho_X} XJ \\
\rho & \downarrow \quad \Upsilon_{\rho X}^\rightarrow \quad r_X \\
X & \xrightarrow{} X
\end{align*}
\]

satisfying the equation

\[
\begin{align*}
XIY \xrightarrow{XuY} XJY \\
\lambda_{XY} K \quad \rho_X \quad \Upsilon_{\rho X Y}^\rightarrow \quad r_{XY} Y \\
XY \xrightarrow{} XY
\end{align*} = \begin{align*}
XIY \xrightarrow{XuY} XJY \\
\lambda_{XY} \quad \Upsilon_{\lambda Y X}^\leftarrow \quad \ell_X Y \quad H \quad r_{XY} Y \\
XY \xrightarrow{} XY
\end{align*}
\]

Finally, a 2-morphism of GPS unit maps is a 2-cell \(T : u \Rightarrow v\) satisfying the
compatibility conditions (15) and (16) of Lemma 5.2.

6.11. Remarks. Note first that \(u\) is automatically an equi-arrow. Observe
also that \(\Upsilon_{u X}^\leftarrow\) and \(\Upsilon_{\rho X Y}^\rightarrow\) completely determine each other by Equation (20), as
is easily seen by taking on the one hand \(X\) to be a left cancellable object and
on the other hand \(Y\) to be a right cancellable object. Finally note that there are
two further equations, expressing compatibility with \(K^\lambda\) and \(K^\rho\), but
they can be deduced from Equation (20), independently of the coherence Axioms (17)
and (18). Here is the one for \(K^\lambda\) for future reference:

\[
\begin{align*}
IXY \xrightarrow{u_{XY}} JXY \\
\lambda_{XY} K^\lambda \quad \lambda_{XY} \quad \Upsilon_{\lambda Y X}^\leftarrow \quad \ell_{XY} Y \\
XY \xrightarrow{} XY
\end{align*} = \begin{align*}
IXY \xrightarrow{u_{XY}} JXY \\
\lambda_{XY} \quad \Upsilon_{\lambda Y X}^\leftarrow \quad \ell_{XY} Y \quad H^\ell \quad \ell_{XY} Y \\
XY \xrightarrow{} XY
\end{align*}
\]

7 Comparison with classical theory (Theorem E)

In this section we prove the equivalence between the two notions of unit.
7.1. From cancellable-idempotent units to GPS units. We fix a unit object \((I, \alpha)\). We also assume chosen a left constraint \(\lambda_X : IX \to X\) with \(L_X : I\lambda_X \equiv \alpha X\), and a right constraint \(\rho_X : XI \to X\) with \(R_X : X\alpha \equiv \rho_X I\). First of all, in analogy with Axioms (2) and (3) of monoidal categories we have:

7.2 Lemma. In the situation of 7.1, there are unique natural invertible 2-cells

\[
\begin{align*}
K^\lambda : \lambda_{XY} &\Rightarrow \lambda_X Y \\
K^\rho : X\rho_Y &\Rightarrow \rho_{XY}
\end{align*}
\]

satisfying

\[
IIXY \xrightarrow{IK^\lambda} IXY = IIXY \xrightarrow{L^{-1}Y} L^{-1}Y \xrightarrow{\lambda_{XY}} IXY \tag{22}
\]

\[
XYII \xrightarrow{K^\rho I} XYI = XYII \xrightarrow{R} XR^{-1} \xrightarrow{\rho_{XY}I} XYI \tag{23}
\]

Proof. The conditions precisely define the 2-cells, since \(I\) is cancellable. \(\square\)

7.3 Lemma. In the situation of 7.1, there is a canonical family of invertible 2-cells (the Kelly cell)

\[
\begin{align*}
K : X\lambda_Y &\Rightarrow \rho_X Y,
\end{align*}
\]

natural in \(X\) and \(Y\).

Proof. This is analogous to the construction of the associator: \(K\) is defined as the unique 2-cell \(K : X\lambda_Y \Rightarrow \rho_X Y\) satisfying the equation

\[
\begin{align*}
XIIY \xrightarrow{X\alpha Y} XIY \xrightarrow{XL} XYY \xrightarrow{\rho_X Y} XY = XIIY \xrightarrow{\lambda_{XY}} XIY \xrightarrow{\rho_X Y} XY \tag{24}
\end{align*}
\]
André Joyal and Joachim Kock

This makes sense since $X\alpha Y$ is an equi-arrow, so we can cancel it away. Clearly $K$ is invertible since $L$ and $R$ are.

We constructed $K^\lambda$ and $K^\rho$ directly from $L$ and $R$. Meanwhile we also constructed $K$, and we know from classical theory (6.5) that this cell determines the two others. The following proposition shows that all these constructions match up, and in particular that the constructed Kelly cell is coherent on both sides:

7.4 Proposition. In the situation of 7.1, the families of 2-cells $K$, $K^\lambda$ and $K^\rho$ (constructed in 7.2 and 7.3) satisfy the GPS unit axioms (17) and (18):

$$
\begin{align*}
X\lambda YZ & \Rightarrow X\lambda YZ \\
X\rho YZ & \Rightarrow \rho_{XY}Z
\end{align*}
$$

Proof. We treat the left constraint (the right constraint being completely analogous). We need to establish

$$
XIYZ \Rightarrow XYZ
$$

and it is enough to establish this equation pre-whiskered with $X\alpha YZ$. In the diagram resulting from the left-hand side:

$$
\begin{align*}
 XIYZ \Rightarrow X\lambda YZ \Rightarrow X\lambda YZ & \Rightarrow X\lambda YZ \\
XK_{Y,Z}^X & \Rightarrow XK_{Y,Z}^X \\
X\lambda YZ & \Rightarrow X\lambda YZ
\end{align*}
$$

we can replace $(X\alpha YZ)\#(K_{X,Y,Z})$ by the expression that defined $K_{X,Y,Z}$
(cf. (24)), yielding altogether

Here we can move the cell $XK_{Y,Z}^{X}$ across the square, where it becomes $XIK_{Y,Z}^{X}$ and combines with $XLYZ$ to give altogether $XLYZ$ (cf. (22)). The resulting diagram

is nothing but

(by Equation (24) again) which is what we wanted to establish. \qed

Hereby we have concluded the construction of a GPS unit from $(I, \alpha)$. We will also need a result for morphisms:

7.5 Proposition. Let $(u, \mathcal{U}) : (I, \alpha) \to (J, \beta)$ be a morphism of units in the sense of 2.9, and consider the two canonical 2-cells $U^{\text{left}}$ and $U^{\text{right}}$ constructed
in Lemma 5.1. Then Equation (20) holds:

\[
\begin{align*}
&X \mapsto Y \\
&\xymatrix{ X \ar@{->}[r]^{X_{X_{Y}}} \ar@{->}[d]_{X_{\lambda_{Y}}} & X_{Y} \ar@{->}[r]^{X_{U_{Y}}} \ar@{->}[d]_{X_{\rho_{Y}}} & X_{Y} \ar@{->}[r]^{X_{X_{Y}}} & X_{Y} } \\
\xymatrix{ X \ar@{->}[r]^{X_{X_{Y}}} \ar@{->}[d]_{X_{\lambda_{Y}}} & X_{Y} \ar@{->}[r]^{X_{U_{Y}}} & X_{Y} & \xymatrix{ X \ar@{->}[r]^{X_{X_{Y}}} \ar@{->}[d]_{X_{\lambda_{Y}}} & X_{Y} \ar@{->}[r]^{X_{U_{Y}}} \ar@{->}[d]_{X_{\rho_{Y}}} & X_{Y} \ar@{->}[r]^{X_{X_{Y}}} & X_{Y} } \\
\xymatrix{ X \ar@{->}[r]^{X_{X_{Y}}} \ar@{->}[d]_{X_{\lambda_{Y}}} & X_{Y} \ar@{->}[r]^{X_{U_{Y}}} & X_{Y} & \xymatrix{ X \ar@{->}[r]^{X_{X_{Y}}} \ar@{->}[d]_{X_{\lambda_{Y}}} & X_{Y} \ar@{->}[r]^{X_{U_{Y}}} \ar@{->}[d]_{X_{\rho_{Y}}} & X_{Y} \ar@{->}[r]^{X_{X_{Y}}} & X_{Y} } }
\end{align*}
\]

(Hence \((u, U^\text{left}, U^\text{right})\) is a morphism of GPS units.)

**Proof.** It is enough to prove the equation obtained by pasting the 2-cell \(X_{U_{Y}}\) on top of each side of the equation. This enables us to use the characterising equation for \(K\) and \(H\). After this rewriting, we are in position to apply Equations (13) and (14), and after cancelling \(R\) and \(L\) cells, the resulting equation amounts to a cube, where it is easy to see that each side is just \(U^\text{left}_{X} U^\text{right}_{Y}\). \(\square\)

7.6. From GPS units to cancellable-idempotent units. Given a GPS unit \((I, \lambda, \rho, K)\), just put

\[
\alpha := \lambda_{I},
\]

then \((I, \alpha)\) is a unit object in the sense of 2.9. Indeed, we already observed that \(I\) is cancellable (6.4), and from the outset \(\lambda_{I}\) is an equi-arrow. That’s all! To construct it we didn’t even need the Kelly cell, or any of the auxiliary cells or their axioms.

7.7. Left and right actions from the Kelly cell. Start with natural left and right constraints \(\lambda\) and \(\rho\) and a Kelly cell \(K : X_{\lambda_{Y}} \Rightarrow \rho_{X_{Y}}\) (not required to be coherent on either side). Construct \(K^\lambda\) as in 6.5, put \(\alpha := \lambda_{I}\), and define left and right actions as follows. We define \(L_X\) as

\[
I_{\lambda_{X}} \xRightarrow{X_{\lambda_{X}}} \lambda_{I_{X}} \Rightarrow \lambda_{I} X = \alpha X,
\]

while we define \(R_X\) simply as

\[
X_{\alpha} = X_{\lambda_{I}} \xRightarrow{K_{X_{I}}} \rho_{X_{I}}.
\]

7.8 Proposition. For fixed \((I, \lambda, \rho, K)\), the following are equivalent:

(i) The left and right 2-cells \(L\) and \(R\) just constructed in 7.7 are compatible with the Kelly cell in the sense of Equation (24).

(ii) The Kelly cell \(K\) is coherent on the left (i.e. satisfies Axiom (17)).

(ii') The Kelly cell \(K\) is coherent on the right (i.e. satisfies Axiom (18)).

**Proof.** Proposition 7.4 already says that (i) implies both (ii) and (ii'). To prove (ii)\(\Rightarrow\)(i), we start with an auxiliary observation: by massaging the naturality
we find the equation

we find the equation
tailor-made to a substitution we shall perform in a moment.

Now for the main computation, assuming first that $K$ is coherent on the left, i.e. that Axiom (17) holds. Start with the left-hand side of Equation (24), and insert the definitions we made for $L$ and $R$ to arrive at
in which we can now substitute (25) to get

\[
\begin{array}{c}
X_{II}Y \\
\downarrow X_{II}Y \\
\downarrow K_{X,Y} \\
\downarrow \rho_{X,Y} \\
X \rightarrow XY
\end{array}
\]

Here finally the three 2-cells incident to the \(X_{II}Y\) vertex cancel each other out, thanks to Axiom (17), and in the end, remembering \(\alpha = \lambda_{I}\), we get

\[
\begin{array}{c}
X_{II}Y \\
\downarrow X_{II}Y \\
\downarrow K_{X,Y} \\
\downarrow \rho_{X,Y} \\
X \rightarrow XY
\end{array}
\]

as required to establish that \(K\) satisfies Equation (24). Hence we have proved (ii)⇒(i), and therefore altogether (ii)⇒(ii'). The converse, (ii')⇒(ii) follows now by left-right symmetry of the statements. (But note that the proof via (i) is not symmetric, since it relies on the definition \(\alpha = \lambda_{I}\). To spell out a proof of (ii')⇒(ii), use rather \(\alpha = \rho_{I}\), observing that the intermediate result (i) would refer to different \(L\) and \(R\).) \(\square\)

We have now given a construction in each direction, but both constructions involved choices. With careful choices, applying one construction after the other in either way gets us back where we started. It is clear that this should constitute an equivalence of 2-categories. However, the involved choices make it awkward to make the correspondence functorial directly. (In technical terms, the constructions are ana-2-functors.) We circumvent this by introducing an intermediate 2-category dominating both. With this auxiliary 2-category, the results we already proved readily imply the equivalence.
7.9. A correspondence of 2-categories of units. Let \( \mathcal{W} \) be following 2-category. Its objects are septuples

\[
(I, \alpha, \lambda, \rho, L, R, K),
\]

with equi-arrows

\[
\alpha : II \to I, \quad \lambda_X : IX \to X, \quad \rho_X : XI \to X,
\]

(and accompanying naturality 2-cell data), and natural invertible 2-cells

\[
L : I\lambda_X \Rightarrow \alpha X, \quad R : X\alpha \Rightarrow \rho_X I, \quad K : X\lambda_Y \Rightarrow \rho_X Y.
\]

These data are required to satisfy Equation (24) (compatibility of \( K \) with \( L \) and \( R \)).

The arrows in \( \mathcal{W} \) from \((I, \alpha, \lambda, \rho, L, R, K)\) to \((J, \beta, \ell, r, L', R', H)\) are quadruples

\[
(u, U_{\text{left}}, U_{\text{right}}, U),
\]

where \( u : I \to J \) is an arrow in \( \mathcal{E} \), \( U_{\text{left}} \) and \( U_{\text{right}} \) are as in 6.10, and \( U \) is a morphism of pseudo-idempotents from \((I, \alpha)\) to \((J, \beta)\). These data are required to satisfy Equation (20) (compatibility with Kelly cells) as well as Equations (13) and (14) in Lemma 5.1 (compatibility with the left and right 2-cells).

Finally a 2-cell from \((u, U_{\text{left}}, U_{\text{right}}, U)\) to \((v, V_{\text{left}}, V_{\text{right}}, V)\) is a 2-cell

\[
T : u \Rightarrow v
\]

required to be a 2-morphism of pseudo-idempotents (compatibility with \( U \) and \( V \) as in 2.5), and to satisfy Equation (15) (compatibility with \( U_{\text{left}} \) and \( V_{\text{left}} \)) as well as Equation (16) (compatibility with \( U_{\text{right}} \) and \( V_{\text{right}} \)).

Let \( \mathcal{E} \) denote the 2-category of cancellable-idempotent units introduced in 2.9, and let \( \mathcal{G} \) denote the 2-category of GPS units of 6.10. We have evident forgetful (strict) 2-functors

\[
\Phi : \mathcal{W} \to \mathcal{E}, \quad \Psi : \mathcal{W} \to \mathcal{G}.
\]

**Theorem E (Equivalence).** The 2-functors \( \Phi \) and \( \Psi \) are 2-equivalences. More precisely they are surjective on objects and strongly fully faithful (i.e. isomorphisms on hom categories).

**Proof.** The 2-functor \( \Phi \) is surjective on objects by Lemma 3.1 and Proposition 7.4. Given an arrow \((u, U)\) in \( \mathcal{E} \) and overlying objects in \( \mathcal{W} \), Lemma 5.1 says there are unique \( U_{\text{left}} \) and \( U_{\text{right}} \), and Proposition 7.5 ensures the required compatibility with Kelly cells (Equation (20)). Hence \( \Phi \) induces a bijection on
objects in the hom categories. Lemma 5.2 says we also have a bijection on the level of 2-cells, hence Φ is an isomorphism on hom categories. On the other hand, Ψ is surjective on objects by 7.7 and Proposition 7.8. Given an arrow \((u, U^\text{left}, U^\text{right})\) in \(\mathcal{W}\), Lemma 7.10 below says that for fixed overlying objects in \(\mathcal{W}\) there is a unique associated \(U\), hence \(Ψ\) induces a bijection on objects in the hom categories. Finally, Lemma 5.2 gives also a bijection of 2-cells, hence \(Ψ\) is strongly fully faithful. ✷

7.10 Lemma. Given a morphism of GPS units

\[
(I, \lambda, \rho, K) \xrightarrow{(u, U^\text{left}, U^\text{right})} (J, \ell, r, H)
\]

fix an equi-arrow \(α : II \simeq I\) with natural families \(L_X : I\lambda_X \Rightarrow αX\) and \(R_X : αX \Rightarrow ρ_X I\) satisfying Equation (24) (compatibility with \(K\)), and fix an equi-arrow \(β : JJ \simeq J\) with natural families \(L'_X : I\ell_X \Rightarrow βX\) and \(R'_X : βX \Rightarrow r_X I\) also satisfying Equation (24) (compatibility with \(H\)). Then there is a unique 2-cell

\[
\begin{array}{c}
II \\
\alpha \downarrow \\
I
\end{array}
\xrightarrow{ uu }
\begin{array}{c}
JJ \\
β \downarrow \\
J
\end{array}
\]

satisfying Equations (13) and (14) (compatibility with \(U^\text{left}\) and the left 2-cells, as well as compatibility with \(U^\text{right}\) and the right 2-cells).

Proof. Working first with left 2-cells, define a family \(W_X\) by the equation

\[
\begin{array}{c}
IIX \\
I\lambda_X \downarrow \\
IX
\end{array}
\xrightarrow{ uuX }
\begin{array}{c}
JJX \\
βX \downarrow \\
JX
\end{array} = \begin{array}{c}
IX \\
αX \downarrow \\
IX \\
\ell_X \downarrow \\
IX \\
\lambda_X \downarrow \\
IX
\end{array}
\xrightarrow{ uuX }
\begin{array}{c}
JJX \\
βX \downarrow \\
JX
\end{array}
\]

It follows readily from Equation (21) that the family has the property

\[W_{XY} = W_X Y\]

for all \(X, Y\), and it is a standard argument that since a unit object exists, for example \((I, \lambda_I)\), this implies that

\[W_X = U X\]

for a unique 2-cell

\[
\begin{array}{c}
II \\
\alpha \downarrow \\
I
\end{array}
\xrightarrow{ uu }
\begin{array}{c}
JJ \\
β \downarrow \\
J.
\end{array}
\]
and by construction this 2-cell has the required compatibility with \( U^{left} \) and the left constraints. To see that this \( U \) is also compatible with \( U^{right} \) and the right constraints we reason backwards: \((u, U)\) is now a morphisms of units from \((I, \alpha)\) to \((J, \beta)\) to which we apply the right-hand version of Lemma 5.1 to construct a new \( U^{new} \), characterised by the compatibility condition. By Proposition 7.5 this new \( U^{new} \) is compatible with \( U^{left} \) and the Kelly cells \( K \) and \( H \) (Equation (20)), and hence it must in fact be the original \( U^{right} \) (remembering from 6.10 that \( U^{left} \) and \( U^{right} \) determine each other via (20)). So the 2-cell \( U \) does satisfy both the required compatibilities.

\[ \square \]

A Criterion for Flatness of Sections of Adjoint Bundle of a Holomorphic Principal Bundle over a Riemann Surface

Indranil Biswas

Received: August 8, 2013
Communicated by Edward Frenkel

Abstract. Let $E_G$ be a holomorphic principal $G$–bundle over a compact connected Riemann surface, where $G$ is a connected reductive affine algebraic group defined over $\mathbb{C}$, such that $E_G$ admits a holomorphic connection. Take any $\beta \in H^0(X, \text{ad}(E_G))$, where $\text{ad}(E_G)$ is the adjoint vector bundle for $E_G$, such that the conjugacy class $\beta(x) \in g/G$, $x \in X$, is independent of $x$. We give a sufficient condition for the existence of a holomorphic connection on $E_G$ such that $\beta$ is flat with respect to the induced connection on $\text{ad}(E_G)$.

Keywords and Phrases: Holomorphic connection, adjoint bundle, flatness, canonical connection

1. Introduction

A holomorphic vector bundle $E$ over a compact connected Riemann surface $X$ admits a holomorphic connection if and only if every indecomposable component of $E$ is of degree zero [We], [At]. This criterion generalizes to the holomorphic principal $G$–bundles over $X$, where $G$ is a connected reductive affine algebraic group defined over $\mathbb{C}$ [AB].

Let $E_G$ be a holomorphic principal $G$–bundle over $X$, where $X$ and $G$ are as above. Let $\mathfrak{g}$ denote the Lie algebra of $G$. Let $\beta$ be a holomorphic section of the adjoint vector bundle $\text{ad}(E_G) = E_G \times^G \mathfrak{g}$. Our aim here is to find a criterion for the existence of a holomorphic connection on $E_G$ such that $\beta$ is flat with respect to the induced connection on $\text{ad}(E_G)$. A sufficient condition is obtained in Theorem 3.4.

For $G = \text{GL}(r, \mathbb{C})$, Theorem 3.4 says the following:
Let $E$ be a holomorphic vector bundle of rank $r$ on $X$, and $\beta \in H^0(X, \text{End}(E))$. Let 

$$E = \bigoplus_{i=1}^t E_i$$

be the generalized eigen-bundle decomposition for $\beta$. So $\beta|_{E_i} = \lambda_i \cdot \text{Id}_{E_i} + N_i$, where $\lambda_i \in \mathbb{C}$, and either $N_i = 0$ or $N_i$ is nilpotent. If $N_i \neq 0$, then assume that the section $N_i^{r_i-1}$ is nowhere vanishing, where $r_i$ is the rank of the vector bundle $E_i$. Also, assume that $E$ admits a holomorphic connection. Then Theorem 3.4 says that $E$ admits a holomorphic connection $D$ such that $\beta$ is flat with respect to the connection on $\text{End}(E)$ induced by $D$.

One may ask whether the above condition that $N_i^{r_i-1}$ is nowhere vanishing whenever $N_i \neq 0$ can be replaced by the weaker condition that the conjugacy class of $\beta(x)$, $x \in X$, is independent of $x$. As example constructed by the referee shows that this cannot be done (see Example 3.6).

2. Flat sections of the adjoint bundle

Let $X$ be a compact connected Riemann surface. Let $G$ be a connected reductive affine algebraic group defined over $\mathbb{C}$. The Lie algebra of $G$ will be denoted by $\mathfrak{g}$. The set of all conjugacy classes in $\mathfrak{g}$ will be denoted by $\mathfrak{g}/G$.

Let

$$(2.1) \quad f : E_G \longrightarrow X$$

be a holomorphic principal $G$–bundle. Define the adjoint vector bundle 

$$\text{ad}(E_G) := E_G \times^G \mathfrak{g}.$$ 

In other words, $\text{ad}(E_G)$ is the quotient of $E_G \times \mathfrak{g}$ where any $(z, v) \in E_G \times \mathfrak{g}$ is identified with $(zg, \text{Ad}(g)(v))$, $g \in G$; here $\text{Ad}(g)$ is the automorphism of $\mathfrak{g}$ corresponding to the automorphism of $G$ defined by $g' \longmapsto g^{-1}g'g$. Therefore, we have a set-theoretic map

$$(2.2) \quad \phi : \text{ad}(E_G) \longrightarrow \mathfrak{g}/G$$

that sends any $(z, v) \in E_G \times \mathfrak{g}$ to the conjugacy class of $v$.

Let

$$\text{At}(E_G) := (f_\ast TE_G)^G \subset f_\ast TE_G$$

be the Atiyah bundle for $E_G$, where $f$ is the projection in (2.1), and $TE_G$ is the holomorphic tangent bundle of $E_G$ (the action of $G$ on $E_G$ produces an action of $G$ on the direct image $f_\ast TE_G$). The Atiyah bundle fits in a short exact sequence of vector bundles

$$(2.3) \quad 0 \longrightarrow \text{ad}(E_G) \longrightarrow \text{At}(E_G) \longrightarrow TX \longrightarrow 0;$$

the above projection $\text{At}(E_G) \longrightarrow TX$, where $TX$ is the holomorphic tangent bundle of $X$, is defined by the differential $df : TE_G \longrightarrow f^\ast TX$ of $f$. A holomorphic connection on $E_G$ is a holomorphic splitting of the sequence in (2.3).
A holomorphic connection \( D \) on \( E_G \) induces a holomorphic connection on each holomorphic fiber bundle associated to \( E_G \). In particular, the vector bundle \( \text{ad}(E_G) \) gets a holomorphic connection from \( D \). A section \( \beta \) of \( \text{ad}(E_G) \) is said to be flat with respect to \( D \) if \( \beta \) is flat with respect to the connection on \( \text{ad}(E_G) \) induced by \( D \).

**Lemma 2.1.** Take a holomorphic connection \( D \) on \( E_G \), and let \( \beta \in H^0(X, \text{ad}(E_G)) \) be flat with respect to \( D \). Then the element \( \phi \circ \beta(x) \in \mathfrak{g}/G \), where \( x \in X \), is independent of \( x \).

**Proof.** Any holomorphic connection on \( X \) is flat because \( \Omega^2_X = 0 \). Using the flat connection \( D \), we may holomorphically trivialize \( E_G \) on any connected simply connected open subset of \( X \). With respect to such a trivialization, the section \( \beta \) is a constant one because it is flat with respect to \( D \). This immediately implies that \( \phi \circ \beta(x) \in \mathfrak{g}/G \) is independent of \( x \in X \). \( \square \)

### 3. Holomorphic Connections on Principal \( G \)-Bundles

A nilpotent element \( v \) of the Lie algebra of a complex semisimple group \( H \) is called regular nilpotent if the dimension of the centralizer of \( v \) in \( H \) coincides with the rank of \( H \) [Hu, p. 53].

As before, \( G \) is a connected reductive affine algebraic group defined over \( \mathbb{C} \). Take \( E_G \) as in (2.1).

**Proposition 3.1.** Take any \( \beta \in H^0(X, \text{ad}(E_G)) \). Assume that

- \( E_G \) admits a holomorphic connection,
- the element \( \phi \circ \beta(x) \in \mathfrak{g}/G \), \( x \in X \), is independent of \( x \), where \( \phi \) is defined in (2.2), and
- for every adjoint type simple quotient \( H \) of \( G \), the section of the adjoint bundle \( \text{ad}(E_H) \) given by \( \beta \), where \( E_H := E_G \times^G H \) is the principal \( H \)-bundle over \( X \) associated to \( E_G \) for the projection \( G \twoheadrightarrow H \), has the property that it is either zero or it is regular nilpotent at some point of \( X \).

Then the principal \( G \)-bundle \( E_G \) admits a holomorphic connection for which \( \beta \) is flat.

**Proof.** Let \( Z := G/[G,G] \) be the abelian quotient. It is a product of copies of \( \mathbb{C}^* \). There are quotients \( H_1, \ldots, H_\ell \) of \( G \) such that

1. each \( H_i \) is simple of adjoint type (the center is trivial), and
2. the natural homomorphism

\[
\varphi : G \to Z \times \prod_{i=1}^\ell H_i
\]

is surjective, and the kernel of \( \varphi \) is a finite group.

Let

\[
E_Z := E_G \times^G Z \quad \text{and} \quad E_{H_i} := E_G \times^G H_i, \quad i \in [1, \ell],
\]
be the holomorphic principal \( Z \)-bundle and principal \( H_i \)-bundle associated to \( E_G \) for the quotient \( Z \) and \( H_i \) respectively. Let \( \text{ad}(E_Z) \) and \( \text{ad}(E_{H_i}) \) be the adjoint vector bundles for \( E_Z \) and \( E_{H_i} \) respectively. Since the homomorphism \( \varphi \) in (3.1) induces an isomorphism of Lie algebras, we have

\[
\text{ad}(E_{G}) = \text{ad}(E_{Z}) \oplus \bigoplus_{i=1}^{\ell} \text{ad}(E_{H_i}).
\]

(3.2)

Let \( \beta_Z \) (respectively, \( \beta_i \)) be the holomorphic section of \( \text{ad}(E_Z) \) (respectively, \( \text{ad}(E_{H_i}) \)) given by \( \beta \) using the decomposition in (3.2). Since the conjugacy class of \( \beta(x) \) is independent of \( x \in X \) (the second condition in the proposition), we conclude that the conjugacy class of \( \beta_i(x) \) is also independent of \( x \in X \). A holomorphic connection on \( E_G \) induces a holomorphic connection on \( E_Z \). Since \( E_Z \) admits a holomorphic connection, and \( Z \) is a product of copies of \( \mathbb{C}^* \), there is a unique holomorphic connection \( D_Z \) on \( E_Z \) whose monodromy lies inside the maximal compact subgroup of \( Z \). The connection on \( \text{ad}(E_Z) \) induced by this connection \( D_Z \) has the property that any holomorphic section of \( \text{ad}(E_Z) \) is flat with respect to it. In particular, the section \( \beta_Z \) is flat with respect to this induced connection on \( \text{ad}(E_Z) \).

Now take any \( i \in [1, \ell] \). A holomorphic connection on \( E_G \) induces a holomorphic connection on \( E_{H_i} \). If the section \( \beta_i \) is zero at some point, then \( \beta_i \) is identically zero because the conjugacy class of \( \beta_i(x) \) is independent of \( x \). Hence, in that case \( \beta_i \) is flat with respect to any connection on \( \text{ad}(E_{H_i}) \). Therefore, assume that \( \beta_i \) is not zero at any point of \( X \).

By the assumption in the proposition, \( \beta_i \) is regularly nilpotent over some point of \( X \). Since the conjugacy class of \( \beta_i(x), x \in X \), is independent of \( x \), we conclude that \( \beta_i \) is regular nilpotent over every point of \( X \). We will now show that the holomorphic principal \( H_i \)-bundle \( E_{H_i} \) is semistable.

For each point \( x \in X \), from the fact that \( \beta_i(x) \) is regular nilpotent we conclude that there is a unique Borel subalgebra \( \mathfrak{b}_x \) of \( \text{ad}(E_{H_i})_x \) such that \( \beta_i(x) \in \mathfrak{b}_x \). [Hu] p. 62, Theorem]. Let

\[
\widetilde{\mathfrak{b}} \subset \text{ad}(E_{H_i})
\]

be the Borel subalgebra bundle such that for every point \( x \) the fiber \( (\widetilde{\mathfrak{b}})_x \) is \( \mathfrak{b}_x \). Fix a Borel subgroup \( B \subset H_i \). Using \( \widetilde{\mathfrak{b}} \), we will construct a holomorphic reduction of structure group of \( E_{H_i} \) to the subgroup \( B \).

Let \( \mathfrak{b} \) be the Lie algebra of \( B \). The Lie algebra of \( H_i \) will be denoted by \( \mathfrak{h}_i \). We recall that \( \text{ad}(E_{H_i}) \) is the quotient of \( E_{H_i} \times \mathfrak{h}_i \) where two points \( (z_1, v_1) \) and \( (z_2, v_2) \) of \( E_{H_i} \times \mathfrak{h}_i \) are identified if there is an element \( h \in H_i \) such that \( z_2 = z_1 h \) and \( v_2 = \text{Ad}(h)(v_1) \), where \( \text{Ad}(h) \) is the automorphism of \( \mathfrak{h}_i \) corresponding to the automorphism \( y \mapsto h^{-1} y h \) of \( H_i \). For any point \( x \in X \), let \( \widetilde{E}_{B,x} \subset (E_{H_i})_x \) be the complex submanifold consisting of all \( z \in (E_{H_i})_x \) such that for all \( v \in \mathfrak{b} \), the image of \( (z, v) \) in \( \text{ad}(E_{H_i})_x \) lies in \( \widetilde{\mathfrak{b}}_x \). Since any two Borel subalgebras of \( \mathfrak{h}_i \) are conjugate, it follows that \( \widetilde{E}_{B,x} \) is nonempty. The normalizer of \( \mathfrak{b} \) in \( H_i \) coincides with \( B \). From this it follows that \( \widetilde{E}_{B,x} \) is preserved by the action of \( B \) on \( (E_{H_i})_x \), with the action of \( B \) on \( E_{B,x} \) being
transitive. Let

\[ E_B \subset E_{H_i} \]

be the complex submanifold such that \( E_B \cap (E_{H_i})_x = E_{B,x} \) for every \( x \in X \). From the above properties of \( E_{B,x} \) it follows immediately that \( E_B \) is a holomorphic reduction of structure group of the principal \( H_i \)-bundle \( E_{H_i} \) to the subgroup \( B \).

Consider the adjoint action of \( B \) on \( b_1 := b/[b, b] \). Let

\[ E_B(b_1) := E_B \times^B b_1 \to X \]

be the holomorphic vector bundle associated to \( E_B \) for the \( B \)-module \( b_1 \). Since \( \beta_i \) is everywhere regular nilpotent, it follows that the vector bundle \( E_B(b_1) \) is trivial. Consequently, for any character \( \chi \) of \( B \) which is a nonnegative integral combination of simple roots, the line bundle \( E_B(\chi) \to X \) associated to \( E_B \) for the character \( \chi \) is trivial \([AAB, p. 708, Theorem 5]\). Therefore, for any character \( \chi \) of \( B \), the line bundle \( E_B(\chi) \) associated to \( E_B \) for \( \chi \) is trivial.

Let \( d \) be the complex dimension of \( h_i \). Consider the adjoint action on \( h_i \). Note that \( \text{ad}(E_{H_i}) \) is identified with the vector bundle associated to the principal \( B \)-bundle \( E_B \) for this \( B \)-module \( h_i \). Since \( B \) is solvable, there is a filtration of \( B \)-modules

\[ 0 = V_0 \subset V_1 \subset \cdots \subset V_{d-1} \subset V_d = h_i \]

such that \( \dim V_j = j \) for all \( j \in [1, d] \). The corresponding filtration of vector bundles associated to \( E_B \) is a filtration of \( \text{ad}(E_{H_i}) \) such that the successive quotients are the line bundles \( E_B(V_j/V_{j-1}), i \in [1, d], \) associated to \( E_B \) for the \( B \)-modules \( V_j/V_{j-1} \). We noted above that the line bundles associated to \( E_B \) for the characters of \( B \) are trivial.

Therefore, we get a filtration of \( \text{ad}(E_{H_i}) \) such that each successive quotient is the trivial line bundle. This immediately implies that the vector bundle \( \text{ad}(E_{H_i}) \) is semistable. Hence the holomorphic principal \( H_i \)-bundle \( E_{H_i} \) is semistable \([AAB, p. 698, Lemma 3]\).

Since \( H_i \) is simple, and \( E_{H_i} \) is semistable, there is a natural holomorphic connection on \( E_{H_i} \) \([BG, p. 20, Theorem 1.1]\) (set the Higgs field in \([BG, Theorem 1.1]\) to be zero). Let \( D^{H_i} \) denote this connection. The vector bundle \( \text{ad}(E_{H_i}) \) being semistable of degree zero has a natural holomorphic connection \([Si, p. 36, Lemma 3.5]\). See also \([BG, p. 20, Theorem 1.1]\). (In both \([Si, Lemma 3.5]\) and \([BG, Theorem 1.1]\) set the Higgs field to be zero.) Let \( D^{\text{ad}} \) denote this holomorphic connection on \( \text{ad}(E_{H_i}) \). This connection \( D^{\text{ad}} \) coincides with the one induced by \( D^{H_i} \) (see the construction of the connection in \([BG]\)). Any holomorphic section of \( \text{ad}(E_{H_i}) \) is flat with respect to \( D^{\text{ad}} \). To see this, let

\[ \phi : O_X \to \text{ad}(E_{H_i}) \]

be the homomorphism given by a nonzero holomorphic section of \( \text{ad}(E_{H_i}) \).

Since image(\( \phi \)) is a semistable subbundle of \( \text{ad}(E_{H_i}) \) of degree zero, the connection \( D^{\text{ad}} \) preserves image(\( \phi \)), and, moreover, the restriction of \( D^{\text{ad}} \) to image(\( \phi \)) coincides with the canonical connection of image(\( \phi \)) \([Si, p. 36, Lemma 3.5]\).
The canonical connection on the trivial holomorphic line bundle image(φ) is the trivial connection (the monodromy is trivial).
In particular, the connection on ad(E_{H_1}) induced by D_{H_1} has the property that the section β is flat with respect to it.
Since the homomorphism of Lie algebras corresponding to φ (in (3.1)) is an isomorphism, if we have holomorphic connections on E_Z and E_{H_1}, [1, ℓ], then we get a holomorphic connection on E_G; simply pullback the connection form using the map

$$E_G \rightarrow E_Z \times X E_{H_1} \times X \cdots \times X E_{H_ℓ}.$$  

The connection on E_G given by the connections on E_Z and E_{H_1}, [1, ℓ], constructed above satisfies the condition that β is flat with respect to it. This completes the proof of the proposition. □

**Lemma 3.2.** Take any semisimple section β_s ∈ H^0(X, ad(E_G)) such that the element φ ◦ β_s(x) ∈ g/G, x ∈ X, is independent of x, where φ is defined in (2.2). Then β_s produces a holomorphic reduction of structure group of E_G to a Levi subgroup of a parabolic subgroup of G. The conjugacy class of the Levi subgroup is determined by φ ◦ β_s(x) ∈ g/G.

**Proof.** Fix an element

$$v_0 \in g$$

such that the image of v_0 in g/G coincides with φ ◦ β_s(x). Let L ⊂ G be the centralizer of v_0. It is known that L is a Levi subgroup of some parabolic subgroup of G [DM, p. 26, Proposition 1.22] (note that L is the centralizer of the torus in G generated by v_0). In particular, L is connected and reductive.
For any point x ∈ X, let F_x ⊂ (E_G)_x be the complex submanifold consisting of all points z such that the image of (z, v_0) in ad(E_G)_x coincides with β_s(x). (Recall that ad(E_G) is a quotient of E_G × g.) Let

$$F_L \subset E_G$$

be the complex submanifold such that F_L \cap (E_G)_x = F_x for all x ∈ X. It is straightforward to check that F_L is a holomorphic reduction of structure group of the principal G-bundle E_G to the subgroup L. □

**Remark 3.3.** If β_s ∈ H^0(X, ad(E_G)) is such that β_s(x) is semisimple for every x ∈ X, then the conjugacy class of β_s(x) is in fact independent of x. But we do not need this here.

From the Jordan decomposition of a complex reductive Lie algebra we know that for any holomorphic section θ of ad(E_G), there is a naturally associated semisimple (respectively, nilpotent) section θ_s (respectively, θ_n) such that θ = θ_s + θ_n.
Take any β ∈ H^0(X, ad(E_G)). Let

$$β = β_s + β_n$$

be the Jordan decomposition. Assume that the element φ ◦ β(x) ∈ g/G, x ∈ X, is independent of x, where φ is defined in (2.2). This implies that
A Criterion for Flatness of Sections of Adjoint Bundle

117

φ ◦ βs(x) ∈ g/G, x ∈ X, is also independent of x. Let (LL, FL) be the principal bundle constructed in Lemma 3.2 from βs. Let H be an adjoint type simple quotient of L. Let

\[ E_H := F_L \times^L H \rightarrow X \]

be the holomorphic principal H–bundle associated to FL for the projection \( \mathbb{L} \rightarrow H \).

Since \([β_s, β_n] = 0\), from the construction of FL it follows that

\[ β_n \in H^0(X, \text{ad}(FL)) \subset H^0(X, \text{ad}(EG)). \]

Therefore, using the natural projection \( \text{ad}(FL) \rightarrow \text{ad}(E_H) \), given by the projection of the Lie algebra \( \text{Lie}(L) \rightarrow \text{Lie}(H) \), the above section \( β_n \) produces a holomorphic section of \( \text{ad}(E_H) \). Let

\[ (3.3) \quad \tilde{β}_n \in H^0(X, \text{ad}(E_H)) \]

be the section constructed from \( β_n \).

THEOREM 3.4. Take any \( β \in H^0(X, \text{ad}(EG)) \). Let \( β = β_s + β_n \) be the Jordan decomposition. Assume that

- \( E_G \) admits a holomorphic connection,
- the element \( φ \circ β(x) \in g/G, x \in X \), is independent of \( x \), where \( φ \) is defined in (2.2), and
- for every adjoint type simple quotient \( H \) of \( L \), the section \( \tilde{β}_n \) in (3.3) of \( \text{ad}(E_H) \) has the property that it is either zero or it is regular nilpotent at some point of \( X \).

Then the principal \( G \)–bundle \( E_G \) admits a holomorphic connection for which \( β \) is flat.

Proof. Note that

\[ β_s \in H^0(X, \text{ad}(FL)) \subset H^0(X, \text{ad}(EG)). \]

In fact, for each point \( x \in X \), the element \( β_s(x) \in \text{ad}(FL)_x \) is in the center of \( \text{ad}(FL)_x \). Consider the abelian quotient

\[ Z_L = \mathbb{L}/[\mathbb{L}, \mathbb{L}]. \]

Let \( F_{Z_L} \) be the holomorphic principal \( Z_L \)–bundle over \( X \) obtained by extending the structure group of the principal \( \mathbb{L} \)–bundle \( F_L \) using the quotient map \( \mathbb{L} \rightarrow Z_L \). The adjoint vector bundle \( \text{ad}(F_{Z_L}) \) is a direct summand of \( \text{ad}(F_L) \). In fact, for each \( x \in X \), the subspace \( \text{ad}(F_{Z_L})_x \subset \text{ad}(F_L)_x \) is the center of the Lie algebra \( \text{ad}(F_L)_x \).

A holomorphic connection on \( F_{Z_L} \) induces a holomorphic connection on \( E_G \). We can now apply Proposition 3.1 to \( F_L \) to complete the proof of the theorem. But for that we need to show that \( F_{Z_L} \) admits a holomorphic connection.

Let \( \mathfrak{l} \) be the Lie algebra of \( \mathbb{L} \). Consider the inclusion of \( \mathbb{L} \)–modules \( \mathfrak{l} \rightarrow \mathfrak{g} \) given by the inclusion of \( \mathbb{L} \) in \( G \). Since \( \mathbb{L} \) is reductive, there is a sub \( \mathbb{L} \)–module \( S \subset \mathfrak{g} \) such that the natural homomorphism

\[ \mathfrak{l} \oplus S \rightarrow \mathfrak{g} \]
is an isomorphism (so $S$ is a complement of $0$). Let

$$p : g \rightarrow l$$

be the projection given by the above decomposition of $g$.

Let $D$ be a holomorphic connection on $E_G$. So $D$ is a holomorphic $1$–form on the total space of $E_G$ with values in the Lie algebra $g$. Let $D'$ be the restriction of this $1$–form to the complex submanifold $F_L \subset E_G$. Consider the $1$–valued $1$–form $p \circ D'$ on $E_L$, where $p$ is the projection in (3.4). This $1$–valued $1$–form on $F_L$ defines a holomorphic connection of the principal $L$–bundle $F_L$. Now Proposition 3.1 completes the proof of the theorem.

We recall that a holomorphic vector bundle $W$ on $X$ has a holomorphic connection if and only if each indecomposable component of $W$ is of degree zero [We], [At, p. 203, Theorem 10]. This criterion generalizes to holomorphic principal $G$–bundles on $X$ (see [AB] for details).

We now set $G = GL(r, \mathbb{C})$ in Theorem 3.4. Let $E$ be a holomorphic vector bundle of rank $r$ on $X$. Take any $\beta \in H^0(X, \text{End}(E))$.

Let

$$E = \bigoplus_{i=1}^{\ell} E_i$$

be the generalized eigen-bundle decomposition of $E$ for $\beta$. Therefore,

$$\beta|_{E_i} = \lambda_i \cdot \text{Id}_{E_i} + N_i,$$

where $\lambda \in \mathbb{C}$, and either $N_i = 0$ or $N_i$ is nilpotent.

Then Theorem 3.4 has the following corollary:

**Corollary 3.5.** For every $N_i \neq 0$, assume that the section $N_i^{r_i - 1}$ of $\text{End}(E_i)$ is nowhere vanishing, where $r_i$ is the rank of the vector bundle $E_i$ in (3.5). If the holomorphic vector bundle $E$ admits a holomorphic connection, then it admits a holomorphic connection $D$ such that the section $\beta$ is flat with respect to the connection on $\text{End}(E)$ induced by $D$.

Consider the condition on $\beta$ in Corollary 3.5, which says that $N_i^{r_i - 1}$ is nowhere vanishing whenever $N_i \neq 0$. This condition implies that the image of $\beta(x)$ in $M(r, \mathbb{C})/GL(r, \mathbb{C})$ is independent of $x \in X$ (here $GL(r, \mathbb{C})$ acts on its Lie algebra $M(r, \mathbb{C})$ via conjugation). Therefore, one may ask whether the above mentioned condition in Corollary 3.5 can be replaced by the weaker condition that the conjugacy class of $\beta(x)$ is independent of $x \in X$. Note that if this can be done, then the sufficient condition in Corollary 3.5 for the existence of a connection on $E$ such that $\beta$ is flat with respect to it actually becomes a necessary and sufficient condition. The following construction of the referee shows that the condition in Corollary 3.5 cannot be replaced by the weaker condition that the conjugacy class of $\beta(x)$ is independent of $x \in X$. 

Example 3.6 (Referee). Let $X$ be of sufficiently high genus. Let $L$ and $M$ be holomorphic line bundles on $X$ of degree 1 and degree $-2$ respectively. Then there exists an indecomposable holomorphic vector bundle $E$ of rank three on $X$ satisfying the following condition: it admits a filtration of holomorphic subbundles

$$L = E_1 \subset E_2 \subset E$$

such that $E_2/L = M$ and $E/E_2 = L$. We omit the detailed arguments given by the referee showing that such a vector bundle $E$ exists. Let $\beta$ denote the composition

$$E \rightarrow E/E_2 = L = E_1 \hookrightarrow E.$$ 

Clearly, the conjugacy class of $\beta(x)$ is independent of $x \in X$. The vector bundle $E$ admits a holomorphic connection because it is indecomposable of degree zero. If $D$ is a holomorphic connection on $E$ such that $\beta$ is flat with respect to the connection on $\text{End}(E)$ induced by $D$, then the subsheaf $\text{image}(\beta) \subset E$ is flat with respect to $D$. But $\text{image}(\beta) = L$ does not admit a holomorphic connection because it is of nonzero degree.

Acknowledgements

The referee pointed out an error in an earlier version of the paper, and also made detailed comments that included Example 3.6. This helped the author to find the right formulation of Theorem 3.4. The author is immensely grateful to the referee for this.

ABSTRACT. We show that points in the intersection of the tropicalizations of subvarieties of a torus lift to algebraic intersection points with expected multiplicities, provided that the tropicalizations intersect in the expected dimension. We also prove a similar result for intersections inside an ambient subvariety of the torus, when the tropicalizations meet inside a facet of multiplicity 1. The proofs require not only the geometry of compactified tropicalizations of subvarieties of toric varieties, but also new results about the geometry of finite type schemes over non-noetherian valuation rings of rank 1. In particular, we prove subadditivity of codimension and a principle of continuity for intersections in smooth schemes over such rings, generalizing well-known theorems over regular local rings. An appendix on the topology of finite type morphisms may also be of independent interest.

1. Introduction

Tropical geometry studies the valuations of solutions to polynomial equations, and may be thought of as a generalization of the theory of Newton polygons to multiple polynomials in multiple variables. It is natural to consider what conditions guarantee that if two closed subvarieties $X$ and $X'$ in a torus $T$ have points with the same valuation, then $X \cap X'$ contains a point of the given valuation. In the context of tropical geometry, this is the question of when tropicalization commutes with intersection. The tropicalization of the intersection of two closed subvarieties of $T$ over a nonarchimedean field is contained in the intersection of their tropicalizations, but this containment is sometimes strict.

For instance, if $X$ is smooth in characteristic zero, and $X'$ is the translate of $X$ by a general torsion point $t$ in $T$, then $X$ and $X'$ are either disjoint or meet transversely, but their tropicalizations are equal. The dimension of $X \cap X'$ is then strictly less than the dimension of $\text{Trop}(X) \cap \text{Trop}(X')$, so there are tropical intersection points that do not lift to algebraic intersection points. In other cases, such as Example 6.2 below, the tropicalizations meet in a positive dimensional set that does not contain the tropicalization of any positive dimensional variety, so at most finitely many of the tropical intersection points can lift to algebraic intersection points. Our main result, in its most basic form, says that the dimension of the tropical intersection is the only obstruction to such lifting.

Following standard terminology from intersection theory in algebraic geometry, we say that $\text{Trop}(X)$ and $\text{Trop}(X')$ meet properly at a point $w$ if $\text{Trop}(X) \cap \text{Trop}(X')$ has codimension $\text{codim} X + \text{codim} X'$ in a neighborhood of $w$. We
say that $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly if they meet properly at every point of their intersection, which may be empty.\footnote{Codimension is subadditive for intersections of tropicalizations, which means that $\text{Trop}(X) \cap \text{Trop}(X')$ has codimension at most $j + j'$ at every point, so $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly if the intersection is either empty or has the smallest possible dimension. See Proposition \ref{proposition:codimension_subadditive}.}

**Theorem 1.1.** Suppose $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly at $w$. Then $w$ is contained in the tropicalization of $X \cap X'$.

In other words, tropicalization commutes with intersections when the intersections have the expected dimension. This generalizes a well-known result of Bogart, Jensen, Speyer, Sturmfels, and Thomas, who showed that tropicalization commutes with intersection when the tropicalizations meet transversely \cite[Lemma 3.2]{BJSST07}. Our proof, and the proofs of all of the other main results below, involves a reduction to the case where the base field is complete with respect to its nonarchimedean norm and the point $w$ is rational over the value group. The reduction is based on the results of Appendix A and should become a standard step in the rigorous application of tropical methods to algebraic geometry. We emphasize that the theorems hold in full generality, over an arbitrary algebraically closed nonarchimedean field, and at any real point in the intersection of the tropicalizations.

Although Theorem 1.1 improves significantly on previously known results, it is still too restrictive for the most interesting potential applications. Frequently, $X$ and $X'$ are closed subvarieties of an ambient variety $Y$ inside the torus. In this case, one cannot hope that $\text{Trop}(X)$ and $\text{Trop}(X')$ will meet properly in the above sense. Instead, we say that the tropicalizations $\text{Trop}(X)$ and $\text{Trop}(X')$ meet properly at a point $w$ in $\text{Trop}(Y)$ if the intersection $\text{Trop}(X) \cap \text{Trop}(X') \subset \text{Trop}(Y)$ has pure codimension $\operatorname{codim} Y X + \operatorname{codim} Y X'$ in a neighborhood of $w$. We extend Theorem 1.1 to proper intersections at suitable points of $\text{Trop}(Y)$, as follows.

Recall that $\text{Trop}(Y)$ is the underlying set of a polyhedral complex of pure dimension $\dim Y$, with a positive integer multiplicity assigned to each facet, by which we mean a maximal face. We say that a point in $\text{Trop}(Y)$ is simple if it is in the interior of a facet of multiplicity 1.

**Theorem 1.2.** Suppose $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly at a simple point $w$ in $\text{Trop}(Y)$. Then $w$ is contained in the tropicalization of $X \cap X'$.

Every point in the tropicalization of the torus is simple, so Theorem 1.2 is the special case of Theorem 1.1 where $Y$ is the full torus $T$. The hypothesis that $w$ be simple is necessary; see Section 6. We strengthen Theorem 1.2 further by showing that where $\text{Trop}(X)$ and $\text{Trop}(X')$ meet properly, the facets of the tropical intersection appear with the expected multiplicities, suitably interpreted. See Theorem 5.1.1 for a precise statement.
The proof of Theorem 1.2 is in two steps. Roughly speaking, we lift first from tropical points to points in the initial degeneration, and then from the initial degeneration to the original variety. Recall that the tropicalization of a closed subvariety $X$ of $T$ is the set of weight vectors $w$ such that the initial degeneration $X_w$ is nonempty in the torus torsor $T_w$ over the residue field.

**Theorem 1.3.** Suppose $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly at a simple point $w$ in $\text{Trop}(Y)$. Then $X_w$ and $X'_w$ have nonempty proper intersection in the smooth variety $Y_w$.

If $w$ is a simple point of $\text{Trop}(Y)$ then standard arguments show that $X_w$ meets $X'_w$ properly at every point in the intersection; the main content of the theorem is that $X_w \cap X'_w$ is nonempty. The proof, given in Section 3, uses extended tropicalizations and the intersection theory of toric varieties. In Section 4, we develop geometric techniques over valuation rings of rank 1 that permit lifting of such proper intersections at smooth points from the special fiber to the generic fiber.

**Theorem 1.4.** Suppose $X_w$ meets $X'_w$ properly at a smooth point $x$ of $Y_w$. Then $x$ is contained in $(X \cap X')_w$.

In particular, if $X_w$ meets $X'_w$ properly at a smooth point of $Y_w$ then $w$ is contained in $\text{Trop}(X \cap X')$. If $w$ is defined over the value group of the nonarchimedean field then surjectivity of tropicalization says that $x$ can be lifted to a point of $X \cap X'$. The dimension theory over valuation rings of rank 1 developed in Section 4 also gives a new proof of surjectivity of tropicalization, as well as density of tropical fibers.

Theorem 1.4 is considerably stronger than Theorems 1.1 and 1.2. It often happens that initial degenerations meet properly even when tropicalizations do not. The proof of this theorem follows standard arguments from dimension theory, but the dimension theory that is needed is not standard because the valuation rings we are working with are not noetherian. We develop the necessary dimension theory systematically in Section 4 using noetherian approximation to prove a version of the Krull principal ideal theorem and then deducing subadditivity of codimension for intersections in smooth schemes of finite type over valuation rings of rank 1. Furthermore, we prove a principle of continuity, showing that intersection numbers are well-behaved in families over valuation rings of rank 1. In Section 5, we apply this principle of continuity to prove a stronger version of Theorem 1.2 with multiplicities and then extend all of these results to proper intersections of three or more subvarieties of $T$.

One special case of these lifting results with multiplicities, for complete intersections, has been applied by Rabinoff in an arithmetic setting to construct canonical subgroups for abelian varieties over $p$-adic fields [Rab12a].

**Remark 1.5.** In addition to their intrinsic appeal, our results are motivated by the possibility of applications to proving correspondence theorems such as the one proved by Mikhalkin for plane curves [Mik05]. Mikhalkin considers curves of fixed degree and genus subject to constraints of passing through specified points.
points. He shows, roughly speaking, that a tropical plane curve that moves in a family of the expected dimension passing through specified points lifts to a predictable number of algebraic curves passing through prescribed algebraic points. Here, we consider points subject to the constraints of lying inside closed subvarieties $X$ and $X'$ and prove the analogous correspondence—if a tropical point moves in a family of the expected dimension inside $\text{Trop}(X) \cap \text{Trop}(X')$ then it lifts to a predictable number of points in $X \cap X'$. One hopes that Mikhalkin’s correspondence theorem will eventually be reproved and generalized using Theorem 1.2 on suitable tropicalizations of moduli spaces of curves. Similarly, one hopes that Schubert problems can be answered tropically using Theorem 1.2 on suitable tropicalizations of Grassmannians and flag varieties. The potential for such applications underlines the importance of having the flexibility to work with intersections inside ambient subvarieties of the torus.

Acknowledgments. We thank B. Conrad, D. Eisenbud, W. Heinzer, D. Rydh, and B. Ulrich for helpful conversations, and are most grateful to J. Rau and M. Rojas for insightful comments on an earlier draft of this work. We also thank the referee for a careful reading.

Part of this research was carried out during the special semesters on Algebraic Geometry and Tropical Geometry at MSRI, in Spring and Fall 2009.

2. Preliminaries

Let $K$ be an algebraically closed field, and let $\nu : K^* \to \mathbb{R}$ be a valuation with value group $G$. Let $R$ be the valuation ring, with maximal ideal $\mathfrak{m}$, and residue field $k = R/\mathfrak{m}$. Since $K$ is algebraically closed, the residue field $k$ is algebraically closed and the valuation group $G$ is divisible. In particular, $G$ is dense in $\mathbb{R}$ unless the valuation $\nu$ is trivial, in which case $G$ is zero. Typical examples of such nonarchimedean fields in equal characteristic are given by the generalized power series fields $K = k((t^G))$, whose elements are formal power series with coefficients in the algebraically closed field $k$ and exponents in $G$, where the exponents occurring in any given series are required to be well-ordered [Poo93].

Let $T$ be an algebraic torus of dimension $n$ over $R$, with character lattice $M \cong \mathbb{Z}^n$, and let $N = \text{Hom}(M, \mathbb{Z})$ be the dual lattice. We write $N_G$ for $N \otimes G$, and $N_R$ for $N \otimes \mathbb{R}$, the real vector space of linear functions on the character lattice. We treat $M$ and $N$ additively and write $x^u$ for the character associated to a lattice point $u$ in $M$, which is a monomial in the Laurent polynomial ring $K[M]$. We write $T$ for the associated torus over $K$.

In this section, we briefly review the basic properties of initial degenerations and tropicalizations, as well as the relationship between tropical intersections and intersections in suitable toric compactifications of $T$. 
2.1. Initial degenerations. Each vector $w$ in $N_R$ determines a weight function on monomials, where the $w$-weight of $ax^u$ is $\nu(a) + \langle u, w \rangle$. The tilted group ring $R[M]^w \subset K[M]$ consists of the Laurent polynomials $\sum a_u x^u$ in which every monomial has nonnegative $w$-weight. We then define $T^w = \operatorname{Spec} R[M]^w$. If $\nu$ is nontrivial, then $T^w$ is an integral model of $T$, which means that it is a scheme over $R$ whose generic fiber $T^w \times_{\operatorname{Spec}R} \operatorname{Spec} K$ is naturally identified with $T$. In general, the scheme $T^w$ carries a natural $T$-action, and is a $T$-torsor if $w$ is in $N_G$.

Remark 2.1.1. If $\nu$ is nontrivial and $w$ is not in $N_G$, or if $\nu$ is trivial and $w$ does not span a rational ray, then $T^w$ is not of finite type over $\operatorname{Spec} R$. Some additional care is required in handling these schemes, but no major difficulties arise for the purposes of this paper. The special fiber $T^w_k$ is still finite type over $k$, and is a torsor over a quotient torus of $T_k$. The basic properties of the schemes $T^w$ and their closed subschemes may be understood by passing to a valued extension field with value group $G'$ such that $w$ is in $N_{G'}$ and analyzing how these schemes and their special fibers transform under such extensions. This analysis is carried out in Appendix A. See, in particular, Theorems A.3 and A.4 and Remark A.5.

For arbitrary $w$ in $N_R$, the scheme $T^w$ is reduced and irreducible, flat over $\operatorname{Spec} R$, and contains $T$ as a dense open subscheme. We define $T^w_w$ to be the closed subscheme cut out by monomials of strictly positive $w$-weight. If the valuation is nontrivial, then $T^w_w$ is the special fiber of $T^w$.

Let $X$ be a closed subscheme of $T$, of pure dimension $d$. Let $X^w$ denote the closure of $X$ in $T^w$.

**Definition 2.1.2.** The initial degeneration $X^w_w$ is the closed subscheme of $T^w_w$ obtained by intersecting with $X^w$.

The terminology reflects the fact that $X^w_w$ is cut out by residues of initial terms (lowest-weight monomials) of Laurent polynomials in the ideal of $X$. If the valuation is nontrivial, then $X^w_w$ is an integral model of $X$, and $X^w_w$ is the special fiber of this model.

One consequence of Gröbner theory is that the space of weight vectors $N_R$ can be decomposed into finitely many polyhedral cells so that the initial degenerations are essentially invariant at points of $N_G$ on the relative interior of each cell, as discussed in more detail in the following subsection. Roughly speaking, the cells are cut out by inequalities whose linear terms have integer coefficients, and whose constant terms are in the value group $G$. More precisely, the cells are integral $G$-affine polyhedra, defined as follows.

**Definition 2.1.3.** An integral $G$-affine polyhedron in $N_R$ is the solution set of a finite number of inequalities

$$\langle u, v \rangle \leq b,$$

with $u$ in the lattice $M$ and $b$ in the value group $G$. 
Lifting Tropical Intersections

An integral $G$-affine polyhedral complex $\Sigma$ is a polyhedral complex consisting entirely of integral $G$-affine polyhedra. In other words, it is a finite collection of integral $G$-affine polyhedra such that every face of a polyhedron in $\Sigma$ is itself in $\Sigma$, and the intersection of any two polyhedra in $\Sigma$ is a face of each. Note that if $G$ is zero, then an integral $G$-affine polyhedron is a rational polyhedral cone, and an integral $G$-affine polyhedral complex is a fan.

2.2. Tropicalization. Following Sturmfels, we define the tropicalization of $X$ to be

$$\text{Trop}(X) = \{w \in \mathbb{N}_G | X_w \text{ is nonempty}\}.$$ 

The foundational theorems of tropical geometry, due to the work of many authors, are the following.

1. The tropicalization $\text{Trop}(X)$ is the underlying set of an integral $G$-affine polyhedral complex of pure dimension $d$.

2. The integral $G$-affine polyhedral structure on $\text{Trop}(X)$ can be chosen so that the initial degenerations $X_w$ and $X_{w'}$ are $T_k$-affinely equivalent for any $w$ and $w'$ in $\mathbb{N}_G$ in the relative interior of the same face.

3. The image of $X(K)$ under the natural tropicalization map $\text{trop} : T(K) \to \mathbb{N}_R$ is exactly $\text{Trop}(X) \cap \mathbb{N}_G$. Here, two subschemes of the $T_k$-torsors $T_w$ and $T_{w'}$ are said to be $T_k$-affinely equivalent if they are identified under some $T_k$-equivariant choice of isomorphism $T_w \cong T_{w'}$. In fact, a stronger statement holds: for any points $w$ and $w'$ in $\mathbb{N}_G$, there exists a $T_k$-equivariant isomorphism $T_w \cong T_{w'}$ which sends $X_w$ to $X_{w'}$ for all $X$ such that $w$ and $w'$ are in the relative interior of the same face of $\text{Trop}(X)$. If the valuation is nontrivial, then it follows from (3) that $\text{Trop}(X)$ is the closure of the image of $X(K)$ under the tropicalization map.

For any extension of valued fields $L|K$, the tropicalization of the base change $\text{Trop}(X_L)$ is exactly equal to $\text{Trop}(X) \setminus \mathbb{N}_G$ in particular, for any algebraically closed extension $L|K$ with nontrivial valuation, $\text{Trop}(X)$ is the closure of the image of $X(L)$. Furthermore, if we extend to some $L$ that is complete with respect to its valuation then the tropicalization map on $X(L)$ extends naturally to a continuous map on the nonarchimedean analytification of $X_L$, in the sense of Berkovich [Ber90], whose image is exactly $\text{Trop}(X)$ [Pay09a]. It follows, by reducing to the case of a complete field, that $\text{Trop}(X)$ is connected if $X$ is connected, since the analytification of a connected scheme over a complete nonarchimedean field is connected.

Remark 2.2.1. The natural tropicalization map from $T(K)$ to $\mathbb{N}_G$ takes a point $t$ to the linear function $u \mapsto \nu \circ \text{ev}_t : x^u$, and can be understood as a coordinatewise valuation map, as follows. The choice of a basis for $M$ induces isomorphisms

\cite{BG84}, \cite{SS04}, and Propositions 2.1.4, Theorem 2.2.1, and Proposition 2.4.5 of [Spe05] for proofs of (1) and (2). The first proposed proof of (3), due to Speyer and Sturmfels, contained an essential gap that is filled by Theorem 4.2.5 below. Other proofs of (3) have appeared in [Dra08 Theorem 4.2], [Gub12 Proposition 4.14] and [Pay09b Pay12]. See also Remark 4.2.6.

Documenta Mathematica 18 (2013) 121–175
$T \cong (K^*)^n$ and $N_R \cong \mathbb{R}^n$. In such coordinates, the tropicalization map sends
$(t_1, \ldots, t_n)$ to $(\nu(t_1), \ldots, \nu(t_n))$.

There is no canonical choice of polyhedral structure on $\text{Trop}(X)$ satisfying (2) in
general, but any refinement of such a complex again satisfies (2). Throughout
the paper, we assume that such a polyhedral complex with underlying set $\text{Trop}(X)$ has been chosen. We refer to its faces and facets as faces and facets of $\text{Trop}(X)$, and refine the complex as necessary.

The tropicalization of a closed subscheme of a torus torsor over $K$ is well-
defined up to translation by $N_G$. In particular, if the value group is zero,
then the tropicalization is well-defined, and is the underlying set of a rational
polyhedral fan. An important special case is the tropicalization of an initial
degeneration. The valuation $\nu$ induces the trivial valuation on the residue
field $k$, and there is a natural identification of $\text{Trop}(X_w)$ with the star of $w$ in $\text{Trop}(X)$ [Spe05, Proposition 2.2.3]. This star is, roughly speaking, the fan one sees looking out from $w$ in $\text{Trop}(X)$; it is constructed by translating $\text{Trop}(X)$ so that $w$ is at the origin and taking the cones spanned by faces of $\text{Trop}(X)$ that contain $w$.

2.3. **Tropical multiplicities.** If $w$ and $w'$ are points of $N_G$ in the relative
interior of the same cone $\sigma$, then $X_w$ and $X_w'$ are $T_k$-affinely equiva-

lent. In particular, they are isomorphic as schemes, so the sum of the multiplicities of their irreducible components are equal. By Theorem [A.4], the sum of the multiplicities of the irreducible components of the initial degeneration at $w$ is invariant under extensions of valued fields, for any $w$ in $N_R$. Since any point in $N_G$ becomes rational over the value group after a suitable extension, it follows that this sum is independent of the choice of $w$ in the relative interior of $\sigma$. We will be concerned with this sum only in the case where $\sigma$ is a facet. For applications of tropical multiplicities at points that are not in the relative
interior of a facet, see [BPR11].

**Definition 2.3.1.** The tropical multiplicity $m(\sigma)$ of a facet $\sigma$ in $\text{Trop}(X)$ is the sum of the multiplicities of the irreducible components of $X_w$, for $w$ in the relative interior of $\sigma$.

For $w \in N_G$, the multiplicities on the facets of $\text{Trop}(X_w)$ agree with those on the facets of $\text{Trop}(X)$ that contain $w$. This is because the initial degeneration of $X_w$ at a point in the relative interior of a given facet is $T_k$-affinely equivalent to the initial degeneration of $X$ at a point in the relative interior of the corresponding facet of $\text{Trop}(X)$. See [Spe05, Proposition 2.2.3] and [Gub12, Proposition 10.9].

Points in the relative interiors of facets of multiplicity 1 will be particularly
important for our purposes.

**Definition 2.3.2.** A simple point in $\text{Trop}(X)$ is a point in the relative interior of a facet of multiplicity 1.

If $w \in N_G$ is a simple point, then the initial degeneration $X_w$ is isomorphic
to a $d$-dimensional torus [Spe05 Proposition 2.2.4], and initial degenerations
at arbitrary simple points are isomorphic to tori of dimension at most \(d\). The latter follows from the case where \(w\) is in \(N_G\) by choosing a suitable extension of valued fields and applying Theorem A.3. In particular, the initial degeneration at an arbitrary simple point is smooth.

The importance of simple points, roughly speaking, is that intersections of tropicalizations of closed subvarieties of \(X\) at simple points behave just like intersections in \(N_\mathbb{R}\) of tropicalizations of closed subvarieties of \(T\). See, for instance, the proof of Theorem 1.2 in Section 5.

### 2.4. Minkowski weights and the fan displacement rule.

We briefly review the language of Minkowski weights and their ring structure, in which the product is given by the fan displacement rule. These tools are the basis of both toric intersection theory, as developed in [FS97], and the theory of stable tropical intersections [RGST05, Mik06], discussed in the following sections. We refer the reader to these original papers for further details. Although the theory of Minkowski weights extends to arbitrary complete fans, we restrict to unimodular fans, corresponding to smooth toric varieties, which suffice for our purposes. Fix a complete unimodular fan \(\Sigma\) in \(N_\mathbb{R}\).

**Definition 2.4.1.** A **Minkowski weight** of codimension \(j\) on \(\Sigma\) is a function \(c\) that assigns an integer \(c(\sigma)\) to each codimension \(j\) cone \(\sigma\) in \(\Sigma\), and satisfies the following balancing condition at every codimension \(j + 1\) cone.

**Balancing Condition.** Let \(\tau\) be a cone of codimension \(j + 1\) in \(\Sigma\). Say \(\sigma_1, \ldots, \sigma_r\) are the codimension \(j\) cones of \(\Sigma\) that contain \(\tau\), and let \(v_i\) be the primitive generator of the image of \(\sigma_i\) in \(N_\mathbb{R}/\text{span}(\tau)\). Then \(c\) is balanced at \(\tau\) if

\[
c(\sigma_1)v_1 + \cdots + c(\sigma_r)v_r = 0
\]

in \(N_\mathbb{R}/\text{span}(\tau)\).

Tropicalizations are one interesting source of Minkowski weights. If \(X\) is a closed subscheme of pure codimension \(j\) in \(T\) and \(\text{Trop}(X)\) is a union of cones in \(\Sigma\), then the function \(c\) given by

\[
c(\sigma) = \begin{cases} m(\sigma) & \text{if } \sigma \subset \text{Trop}(X), \\ 0 & \text{otherwise}. \end{cases}
\]

satisfies the balancing condition, and hence is a Minkowski weight of codimension \(j\). This correspondence between tropicalizations and Minkowski weights is compatible with intersection theory in the toric variety \(Y(\Sigma)\). See Section 2.7 below.

We write \(\text{Mink}^j(\Sigma)\) for the group of Minkowski weights of codimension \(j\) on \(\Sigma\). The direct sum

\[
\text{Mink}^j(\Sigma) = \bigoplus_j \text{Mink}^j(\Sigma)
\]

naturally forms a graded ring, whose product is given by the fan displacement rule, as follows. Let \(v\) be a vector in \(N_\mathbb{R}\) that is sufficiently general so that for any two cones \(\sigma\) and \(\sigma'\) in \(\Sigma\), the displaced cone \(\sigma' + v\) meets \(\sigma\) properly. The
set of such vectors is open and dense in $N_R^\mathbb{R}$; it contains the complement of a finite union of linear spaces. For each cone $\sigma$ in $\Sigma$, let $N_{\sigma}$ denote the sublattice of $N$ generated by $\sigma \cap N$. Note that if $\sigma$ intersects the displaced cone $\sigma' + v$ then $\sigma$ and $\sigma'$ together span $N_R^\mathbb{R}$, so the index $[N : N_{\sigma} + N_{\sigma'}]$ is finite.

**Fan Displacement Rule.** The product $c \cdot c'$ is the Minkowski weight of codimension $j + j'$ given by

$$(c \cdot c')(\tau) = \sum_{\sigma, \sigma'} [N : N_{\sigma} + N_{\sigma'}] \cdot c(\sigma) \cdot c'(\sigma'),$$

where the sum is over cones $\sigma$ and $\sigma'$ containing $\tau$, of codimensions $j$ and $j'$ respectively, such that the intersection $\sigma \cap (\sigma' + v)$ is nonempty.

The balancing conditions on $c$ and $c'$ ensure that the product is independent of the choice of displacement vector $v$, and also satisfies the balancing condition.

2.5. Toric intersection theory. We briefly recall the basics of intersection theory in smooth complete toric varieties. As in the previous section, we fix a complete unimodular fan $\Sigma$ in $N_R^\mathbb{R}$. Let $Y(\Sigma)$ be the associated smooth complete toric variety. A codimension $j$ cycle in $Y(\Sigma)$ is a formal sum of codimension $j$ closed subvarieties, with integer coefficients, and we write $A^j(Y(\Sigma))$ for the Chow group of codimension $j$ cycles modulo rational equivalence. Let $X$ be a closed subscheme of pure codimension $j$ in $Y(\Sigma)$. We write $[X]$ for the class it represents in $A^j(Y(\Sigma))$: by definition, this is the sum over the irreducible components $Z$ of $X$ of the length of $X$ along $Z$ times the class $[Z]$.

Intersection theory gives a natural ring structure on the direct sum

$$A^\ast(Y(\Sigma)) = \bigoplus_j A^j(Y(\Sigma)).$$

If $X$ and $X'$ have complementary dimension, which means that $\dim X + \dim X' = \dim Y(\Sigma)$, then the product $[X] \cdot [X']$ is a zero-dimensional cycle class. The degree of this class, which is the sum of the coefficients of any representative cycle, is denoted $\deg([X] \cdot [X'])$. In particular, if $\sigma$ is a cone of codimension $j$ in $\Sigma$, with $V(\sigma)$ the associated closed $T$-invariant subvariety, then $X$ and $V(\sigma)$ have complementary dimension. We write $c_X$ for the induced function on codimension $j$ cones, given by

$$c_X(\sigma) = \deg([X] \cdot [V(\sigma)]).$$

The fact that the intersection product respects rational equivalence ensures that $c_X$ satisfies the balancing condition and is therefore a Minkowski weight of codimension $j$ on $\Sigma$. The main result of [FS97] then says that there is a natural isomorphism of rings

$$A^\ast(Y(\Sigma)) \xrightarrow{\sim} \text{Mink}^\ast(\Sigma)$$

taking the Chow class $[X]$ to the Minkowski weight $c_X$. The theory of refined intersections says that the product $[X] \cdot [X']$ of the classes of two pure-dimensional closed subschemes of a smooth variety $Y$ is not only
a well-defined cycle class in that smooth variety, but also the Gysin push-forward of a well-defined cycle class in the intersection $X \cap X'$. If $X$ and $X'$ meet properly, then this class has codimension zero, and hence can be written uniquely as a formal sum of the components of $X \cap X'$. The coefficient of a component $Z$ of the intersection is called the intersection multiplicity of $X$ and $X'$ along $Z$, and is denoted $i(Z; X, X')$. It is a positive integer, less than or equal to the length of the scheme theoretic intersection of $X$ and $X'$ along the generic point of $Z$, by [Ful98, Proposition 7.1], and can be computed by Serre’s alternating sum formula

$$i(Z; X, X') = \sum_j (-1)^j \text{length}_{\mathcal{O}_Y} \text{Tor}_j^{\mathcal{O}_Y, \mathcal{O}_Z}(\mathcal{O}_X, \mathcal{O}_{X'}).$$

See [Ful98, Chapter 8] for further details on the theory of refined intersections in smooth varieties.

**Definition 2.5.1.** If $X$ and $X'$ meet properly in a smooth variety $Y$, then the refined intersection cycle is

$$X \cdot X' = \sum_Z i(Z; X, X'; Y) Z,$$

where the sum is over all irreducible components $Z$ of $X \cap X'$.

We will consider such refined intersections inside the torus $T$, as well as in its smooth toric compactifications. Finally, it is useful to work not only with tropicalizations of closed subschemes of $T$, but also with tropicalizations of these refined intersection cycles.

**Definition 2.5.2.** Let $a_1Z_1 + \cdots + a_rZ_r$ be a pure-dimensional cycle in $T$, with positive integer coefficients $a_i$. The tropicalization of this cycle is the union

$$\text{Trop}(a_1Z_1 + \cdots + a_rZ_r) = \text{Trop}(Z_1) \cup \cdots \cup \text{Trop}(Z_r)$$

with multiplicities

$$m_{Z_i}(\tau) = a_1m_{Z_i}(\tau) + \cdots + a_rm_{Z_i}(\tau),$$

where $m_{Z_i}(\tau)$ is defined to be zero if $\text{Trop}(Z_i)$ does not contain $\tau$.

2.6. **Stable tropical intersections.** Many papers have introduced and studied analogues of intersection theory in tropical geometry, including [AK10, BldM11, Kat12, Mik06, RGST05, Tab08]. Here we are interested in only one basic common feature of these theories, the stable tropical intersection, and its compatibility with intersection theory in toric varieties. The key point is that stable tropical intersections are defined combinatorially, depending only on the polyhedral geometry of the tropicalizations, by a local displacement rule. Compatibility with the multiplication rule for Minkowski weights and algebraic intersections of generic translates is discussed in the following section.

Given closed subschemes $X$ and $X'$ of $T$, of pure codimensions $j$ and $j'$, respectively, the stable intersection $\text{Trop}(X) \cdot \text{Trop}(X')$ is a polyhedral complex
of pure codimension $j + j'$, with support contained in the set-theoretic intersection $\text{Trop}(X) \cap \text{Trop}(X')$, and with appropriate multiplicities on its facets, satisfying the balancing condition. Many different closed subschemes of $T$ may have the same tropicalization, but the stable intersection depends only on the tropicalizations.

Suppose the valuation is trivial, so $\text{Trop}(X)$ and $\text{Trop}(X')$ are fans, and let $\tau$ be a face of $\text{Trop}(X) \cap \text{Trop}(X')$ of codimension $j + j'$ in $\mathbb{N}$. The tropical intersection multiplicity of $\text{Trop}(X)$ and $\text{Trop}(X')$ along $\tau$, is given by

$$i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum_{\sigma, \sigma'} [N : N_{\sigma} + N_{\sigma'}] \cdot m(\sigma) \cdot m(\sigma'),$$

where $\sigma$ and $\sigma'$ are facets of $\text{Trop}(X)$ and $\text{Trop}(X')$, respectively, such that the intersection $\sigma \cap (\sigma' + v)$ is nonempty, and $v \in \mathbb{N}$ is a fixed generic displacement vector, as in Section 2.4.

In the general case, where the valuation may be nontrivial, the tropical intersection multiplicities are defined similarly, by a local displacement rule, as follows. Let $\tau$ be a face of codimension $j + j'$ in $\text{Trop}(X) \cap \text{Trop}(X')$, and for each face $\sigma$ containing $\tau$, let $N_{\sigma}$ be the sublattice of $\mathbb{N}$ parallel to the affine span of $\sigma$.

**Definition 2.6.1.** The tropical intersection multiplicity $i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'))$ is given by the local displacement rule

$$i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum_{\sigma, \sigma'} [N : N_{\sigma} + N_{\sigma'}] \cdot m(\sigma) \cdot m(\sigma'),$$

where $v \in \mathbb{N}$ is a generic displacement vector, as above, and the sum is over facets $\sigma$ and $\sigma'$ of $\text{Trop}(X)$ and $\text{Trop}(X')$, respectively, such that the intersection $\sigma \cap (\sigma' + \epsilon v)$ is nonempty for $\epsilon$ sufficiently small and positive.

**Definition 2.6.2.** The stable tropical intersection, denoted $\text{Trop}(X) \cdot \text{Trop}(X')$, is the union of those faces $\tau$ such that $i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'))$ is positive, weighted by their tropical intersection multiplicities.

2.7. **Compatibility of toric and stable tropical intersections.** As discussed in Section 2.4, tropical multiplicities satisfy the balancing condition, and hence give Minkowski weights. The stable tropical intersections are compatible with multiplication of Minkowski weights, and algebraic intersections of generic translates in the torus, as follows.

Let $X$ be a closed subscheme of pure codimension $j$ in $T$. Suppose the valuation is trivial, so $\text{Trop}(X)$ is a fan. After subdividing, we may assume this fan is unimodular, and extends to a complete unimodular fan $\Sigma$ in $\mathbb{N}$. Let $Y(\Sigma)$ be the associated smooth complete toric variety, and let $\overline{X}$ be the closure of $X$ in $Y(\Sigma)$. Because $\Sigma$ contains $\text{Trop}(X)$ as a subfan, the closure $\overline{X}$ meets every torus orbit $O_\tau$ properly, and the intersection is nonempty if and only if $\tau$ is contained in $\text{Trop}(X)$. This follows from the basic properties of extended tropicalizations, given in [Pay09a, Proposition 3.7].
Remark 2.7.1. Indeed the closure $\overline{X}$ is proper and meets every torus orbit properly if and only if $\Sigma$ contains a subfan whose support is $\text{Trop}(X)$. See [Gub12, Section 14].

Furthermore, for any facet $\sigma$ of $\text{Trop}(X)$, the tropical multiplicity $m(\sigma)$ is equal to the intersection number of the closure $\overline{X}$ with the torus invariant subvariety corresponding to $\sigma$, that is

$$m(\sigma) = \deg([X] \cdot V(\sigma)).$$

In other words,

$$c_X(\sigma) = \begin{cases} m(\sigma) & \text{if } \sigma \subset \text{Trop}(X), \\ 0 & \text{otherwise.} \end{cases}$$

See [ST08, Lemma 3.2] for the case of a tropical compactification and [KP11, Lemma 2.3] for the general case.

Lemma 2.7.2. Suppose the valuation is trivial, and let $X$ be a pure-dimensional closed subscheme of $T$. Then the tropicalization $\text{Trop}(X)$ is equal to the tropicalization of the fundamental cycle $\text{Trop}([X])$.

Recall that the multiplicities of facets in the tropicalization of a cycle are defined by linearity; see Definition 2.5.2.

Proof. The tropicalizations agree set-theoretically, because both are the closures of the images of $X(L)$ where $L/K$ is an algebraically closed valued extension field with nontrivial valuation. The multiplicities agree because the tropical multiplicity of a facet $\sigma$ in $\text{Trop}(X)$ is $m(\sigma) = \deg([X] \cdot V(\sigma))$, and this degree is a linear function of the cycle $[X]$. □

Remark 2.7.3. The tropicalization of a pure-dimensional closed subscheme of $T$ also agrees with the tropicalization of its underlying cycle in the case of a nontrivial valuation, but this requires considerably more work. This is deduced from our general results on intersection multiplicities over valuation rings of rank 1 in Corollary 4.4.9. See also [Gub12, Section 13] for an analytic proof using nonarchimedean GAGA and Gubler’s theory of cycles and Cartier divisors on affinoid spaces.

Now consider the general case, where the valuation may be nontrivial, and let $w \in N_G$ be a point of $\text{Trop}(X)$. After subdividing, we may assume that the star of $w$ in $\text{Trop}(X)$ is unimodular, and extends to a complete unimodular fan $\Sigma$. We write $X_w$ for the closure of $X_w$ in $Y(\Sigma)$.

Definition 2.7.4. If $\sigma$ is a facet of $\text{Trop}(X)$ that contains $w$ then let

$$\sigma_w = \mathbb{R}_{\geq 0}(\sigma - w)$$

be the corresponding cone in $\Sigma$.

Recall that the star of $w$ in $\text{Trop}(X)$ is the tropicalization of the initial degeneration $X_w$ and, as discussed in Section 2.4.3 the initial degeneration of $X_w$ at a point in the relative interior of $\sigma_w$ is $T_k$-affinely equivalent to the initial degeneration of $X$ at a point of $N_G$ in the relative interior of $\sigma$. In particular, the
tropical multiplicity \( m(\sigma_w) \) in \( \text{Trop}(X_w) \) is equal to the tropical multiplicity \( m(\sigma) \).

**Lemma 2.7.5.** Let \( \gamma \) be a face of codimension \( j \) in \( \Sigma \). Then

\[
\langle \alpha_{X_w} \cdot \alpha_{X_w} \rangle(\gamma) = \begin{cases} 
    m(\sigma) & \text{if } \gamma = \sigma_w, \text{ for some } \sigma \subset \text{Trop}(X), \\
    0 & \text{otherwise}.
\end{cases}
\]

**Proof.** This follows from the case of the trivial valuation and the fact that the tropical multiplicity \( m(\sigma) \) in \( \text{Trop}(X) \) is equal to the tropical multiplicity \( m(\sigma_w) \) in \( \text{Trop}(X_w) \).

This correspondence between tropical multiplicities and Minkowski weights is compatible with intersections; stable tropical intersections corresponding to products of Minkowski weights, as follows. Suppose \( X' \) is a closed subscheme of pure codimension \( j' \) in \( T \), and \( \tau \) is a face of codimension \( j + j' \) in \( \text{Trop}(X) \cap \text{Trop}(X') \) that contains \( w \). We may assume that the star of \( w \) in \( \text{Trop}(X') \) is a subfan of the unimodular fan \( \Sigma \), and we write \( X_w \) for the closure of \( X_w' \) in \( Y(\Sigma) \).

**Proposition 2.7.6.** Let \( \gamma \) be a cone of codimension \( j + j' \) in \( \Sigma \). Then

\[
\langle \alpha_{X_w} \cdot \alpha_{X_w} \rangle(\gamma) = \begin{cases} 
    i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) & \text{if } \gamma = \tau_w, \\
    0 & \text{otherwise},
\end{cases}
\]

**Proof.** Suppose \( \gamma = \tau_w \). We claim that the displacement rules giving \( \langle \alpha_{X_w} \cdot \alpha_{X_w} \rangle(\gamma) \) and \( i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) \) agree, term by term. If \( \sigma \) and \( \sigma' \) are facets of \( \text{Trop}(X) \) and \( \text{Trop}(X') \), respectively, that contain \( \tau \), then \( \sigma \) meets \( \sigma' + e\nu \) for small positive \( \nu \) if and only if \( \sigma_w \) meets \( \sigma_w' + v \). Then we have an equality of sums of displacements in the displacement rules,

\[
[N : N_{\sigma} + N_{\sigma'}] \cdot m(\sigma) \cdot m(\sigma') = [N : N_{\sigma_w} + N_{\sigma_w'}] \cdot \alpha_{X_w}(\sigma_w) \cdot \alpha_{X_w}(\sigma_w'),
\]

because \( N_{\sigma} + N_{\sigma'} \), \( m(\sigma) \), and \( m(\sigma') \) are equal to \( N_{\sigma_w} + N_{\sigma_w'} \), \( \alpha_{X_w}(\sigma_w) \), and \( \alpha_{X_w}(\sigma_w') \), respectively. The Minkowski weights \( \alpha_{X_w} \) and \( \alpha_{X_w} \) vanish on cones that do not come from facets of \( \text{Trop}(X) \) and \( \text{Trop}(X') \), respectively. Therefore, all nonzero summands in the displacement rules are accounted for in the equality above, and the proposition follows.

It follows that the star of \( w \) in the stable tropical intersection \( \text{Trop}(X) \cdot \text{Trop}(X') \) is exactly the union of the faces of \( \Sigma \) on which \( \langle \alpha_{X_w} \cdot \alpha_{X_w} \rangle \) is positive, with multiplicities given by this product of Minkowski weights.

We now return to the case of the trivial valuation. As above, we choose \( \Sigma \) to be a complete unimodular fan in \( N_{\mathbb{R}} \) that contains \( \text{Trop}(X) \) and \( \text{Trop}(X') \) as subfans.

**Proposition 2.7.7.** Suppose the valuation is trivial. Assume \( X \) meets \( X' \) properly in \( T \) and, moreover, \( X \cap V(\sigma) \) meets \( X' \cap V(\sigma) \) properly in \( V(\sigma) \) for each \( \sigma \in \Sigma \).
Then, for any face $\tau$ of $\text{Trop}(X) \cap \text{Trop}(X')$ of codimension $j + j'$ in $\mathbb{R}$, the tropical intersection multiplicity along $\tau$ is equal to the weighted sum of multiplicities of tropicalizations

$$i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum Z i(Z, X \cdot X'; T) m_Z(\tau),$$

where the sum is over components $Z$ of $X \cap X'$ such that $\text{Trop}(Z)$ contains $\tau$, with tropical multiplicity $m_Z(\tau)$.

**Proof.** First of all, by the preceding proposition,

$$i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = (\text{c}_{X} \cdot \text{c}_{X'})(\tau).$$

Next, the isomorphism from $\text{Mink}^*(\Sigma)$ to $A^*(Y(\Sigma))$ identifies $(\text{c}_{X} \cdot \text{c}_{X'})(\tau)$ with the intersection number $\deg([X] \cdot [X'] \cdot V(\tau))$. By hypothesis, $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly in $Y(\Sigma)$, and the generic point of each component of the intersection lies in $T$, so we have the refined intersection

$$\text{Trop}(X) \cdot \text{Trop}(X') = \sum Z i(Z, X \cdot X'; T)[Z],$$

where the sum is taken over components $Z$ of $X \cap X'$. Therefore,

$$\deg([X] \cdot [X'] \cdot [V(\tau)]) = \sum Z i(Z, X \cdot X'; T) \deg([Z] \cdot [V(\tau)]).$$

Now, since $\text{Trop}(X)$ and $\text{Trop}(X')$ are subfans of $\Sigma$, the closures $\text{Trop}(X)$ and $\text{Trop}(X')$ meet $V(\sigma)$ properly in $Y(\Sigma)$, for all $\sigma \in \Sigma$. Furthermore, by hypothesis, $\text{Trop}(X) \cap V(\sigma)$ and $\text{Trop}(X') \cap V(\sigma)$ meet properly in $V(\sigma)$ for all $\sigma$. It follows that $Z$ meets all orbits of $Y(\Sigma)$ properly. Therefore $\text{Trop}(Z)$ is a union of cones of codimension $j + j'$ in $\Sigma$ (see Remark 2.7.1) and the intersection number $\deg([Z] \cdot [V(\tau)])$ is equal to the tropical multiplicity $m_Z(\tau)$.

The following proposition may be seen as a geometric explanation for the existence of well-defined stable tropical intersections, in the case of the trivial valuation; they are exactly the tropicalizations of intersections of generic translates in the torus.

**Proposition 2.7.8.** Suppose the valuation is trivial, and let $t$ be a general point in $T$. Then $X$ meets $tX'$ properly and the tropicalization of the intersection scheme $X \cap tX'$ is exactly the stable tropical intersection $\text{Trop}(X) \cdot \text{Trop}(X')$.

**Proof.** First, an easy Bertini argument shows that $X$ meets $tX'$ properly when $t$ is general. Furthermore, since $Y(\Sigma)$ is smooth, subadditivity of codimension says that every component of $\text{Trop}(X) \cap t\text{Trop}(X')$ has codimension at most $j + j'$. Say $Z$ is a component of this intersection, and let $O_\sigma$ be the torus orbit in $Y(\Sigma)$ that contains the generic point of $Z$. Now, $\text{Trop}(X) \cap t\text{Trop}(X')$ meets $O_\sigma$ properly, since their tropicalizations are subfans of $\Sigma$, and $\text{Trop}(X) \cap O_\sigma$ meets $t\text{Trop}(X') \cap O_\sigma$ properly in $O_\sigma$, since $t$ is general. Therefore $Z$ has codimension $j + j' + \text{codim} O_\sigma$, and hence $O_\sigma$ must be the dense torus $T$. 

*Documenta Mathematica 18 (2013) 121–175*
Next, the Cohen-Macaulay locus in an excellent scheme is open [Gro65, Scholium 7.8.3(iv)], and contains every generic point, so the Cohen-Macaulay loci of \(X\) and \(X'\) are open and dense. Therefore, since \(t\) is general, the generic point of every component of \(X \cap tX'\) must lie in the Cohen-Macaulay loci of both \(X\) and \(X'\). Then, by [Ful98, Example 8.2.7], the intersection multiplicity \(i(Z, X \cdot tX'; T)\) is equal to the length of the intersection of \(X\) and \(tX'\) along the generic point of \(Z\). Proposition 2.7.7 then says that

\[
i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum_Z \text{length}(\mathcal{O}_{Z, X \cap tX'}) m_Z(\tau).
\]

Now the right hand side is the multiplicity of \(\tau\) in the tropicalization of the cycle \([X \cap tX']\), and the proposition follows, by Lemma 2.7.2. \(\square\)

**Remark 2.7.9.** We apply this proposition in the proof of Lemma 3.3.3. All that is needed for that application is the standard fact that the intersection multiplicity at a point of proper intersection is strictly positive. In particular, the equality of the intersection multiplicity \(i(Z, X \cdot tX'; T)\) with the length of the scheme-theoretic intersection of \(X\) and \(X'\) along \(Z\) is not needed for the main lifting theorems.

In Section 5, we extend Proposition 2.7.8 to the general case, where the valuation may be nontrivial, as an application of tropical lifting theorems. See Theorem 5.3.3.

### 3. The trivial valuation case

The first step in our approach to tropical lifting theorems is to understand how the intersection of \(\text{Trop}(X)\) and \(\text{Trop}(X')\) near a point \(w\) relates to the intersection of the initial degenerations \(X_w\) and \(X'_w\). If \(w\) is in \(N_G\) then the stars of \(w\) in \(\text{Trop}(X)\) and \(\text{Trop}(X')\) are the tropicalizations of \(X_w\) and \(X'_w\), respectively, with respect to the trivial valuation, so this amounts to understanding how tropicalization relates to intersections when the tropicalizations meet properly and the valuation is trivial. Our proof that tropicalization commutes with intersection in this case uses both the theory of extended tropicalizations as projections of nonarchimedean analytifications and a new result about the support of stable intersections of tropicalizations (Lemma 3.3.3). We prove two necessary lemmas about the topology of extended tropicalizations in the general case, where the valuation is not necessarily trivial, since the arguments are identical to those in the case where the valuation is trivial.

#### 3.1. Topology of extended tropicalizations

The extended tropicalizations of \(Y(\Sigma)\) and its closed subschemes were introduced by Kajiwara [Kaj08], and their basic properties were studied further in Section 3 of [Pay09a], to which we refer the reader for further details. We recall the definition and prove that the extended tropicalization of a closed subscheme \(X\) in which the torus \(T\) is dense is the closure of the ordinary tropicalization of \(X \cap T\). We also characterize the closure in the extended tropicalization \(\text{Trop}(Y(\Sigma))\) of a cone \(\sigma\) in \(\Sigma\).
Let $\Sigma$ be a fan in $\mathbb{N}^\mathbb{R}$, and let $Y(\Sigma)$ be the associated toric variety. Recall that each cone $\sigma$ in $\Sigma$ corresponds to an affine open subvariety $U_\sigma$ of $Y(\Sigma)$ whose coordinate ring is the semigroup ring $K[\sigma^\vee \cap M]$ associated to the semigroup of lattice points in the dual cone $\sigma^\vee$ in $M_\mathbb{R}$. Let $\mathbb{R}$ be the real line extended in the positive direction

$$\mathbb{R} = \mathbb{R} \cup \{+\infty\},$$

which is a semigroup under addition, with identity zero. Then

$$\text{Trop}(U_\sigma) = \text{Hom}(\sigma^\vee \cap M, \mathbb{R})$$

is the space of all semigroup homomorphisms taking zero to zero, with its natural topology as a subspace of $\mathbb{R}^{\sigma^\vee \cap M}$. For each face $\tau$ of $\Sigma$, let $N(\tau)$ be the real vector space $N(\tau) = \mathbb{N}^\mathbb{R}/\text{span}(\tau)$. Then $\text{Trop}(U_\sigma)$ is naturally a disjoint union of the real vector spaces $N(\tau)$, for $\tau \preceq \sigma$, where $N(\tau)$ is identified with the subset of semigroup homomorphisms that are finite exactly on the intersection of $\tau^\perp$ with $\sigma^\vee \cap M$.

The tropicalization $\text{Trop}(Y(\Sigma))$ is constructed by gluing the spaces $\text{Trop}(U_\sigma)$ for $\sigma \in \Sigma$ along the natural open inclusions $\text{Trop}(U_\tau) \subseteq \text{Trop}(U_\sigma)$ for $\tau \preceq \sigma$. It is a disjoint union

$$\text{Trop}(Y(\Sigma)) = \bigcup_{\sigma \in \Sigma} N(\sigma),$$

just as $Y(\Sigma)$ is the disjoint union of the torus orbits $O_\sigma$. Points in $N(\sigma)$ may be seen as weight vectors on monomials in the coordinate ring of $O_\sigma$, and the tropicalization of a closed subscheme $X$ in $Y(\Sigma)$ is defined to be

$$\text{Trop}(X) = \bigcup_{\sigma \in \Sigma} \{w \in N(\sigma) \mid (X \cap O_\sigma)_w \text{ is not empty}\}.$$

In other words, $\text{Trop}(X)$ is the disjoint union of the tropicalizations of its intersections with the $T$-orbits in $Y(\Sigma)$. This space is compact when $\Sigma$ is complete.

**Lemma 3.1.1.** If every component of $X$ meets the dense torus $T$, then $\text{Trop}(X)$ is the closure in $\text{Trop}(Y(\Sigma))$ of the ordinary tropicalization $\text{Trop}(X \cap T)$.

**Proof.** Since tropicalizations are invariant under extensions of valued fields [Pay09a, Proposition 6.1], and the completion of the algebraically closed field $K$ is algebraically closed [BGR84, Proposition 3.4.1.3], we may assume the field $K$ is complete with respect to its valuation.

The tropicalization map from $X(K)$ to $\text{Trop}(Y(\Sigma))$ extends to a proper continuous map on the nonarchimedean analytification $X^\text{an}$ whose image is $\text{Trop}(X)$ [Pay09a, Section 2]. Since the open subset $(X \cap T)^\text{an}$ is dense in $X^\text{an}$ [Ber90, Corollary 3.4.5] and maps onto $\text{Trop}(X \cap T)$, the extended tropicalization $\text{Trop}(X)$ is contained in the closure of $\text{Trop}(X \cap T)$. The lemma follows, since $\text{Trop}(X)$ is closed. $\square$
Lemma 3.1.2. Let $\sigma$ and $\tau$ be faces of $\Sigma$, and let $\overline{\sigma}$ be the closure of $\sigma$ in $\text{Trop}(Y(\Sigma))$. Then

$$\overline{\sigma} \cap N(\tau) = \sigma,$$

if $\sigma$ contains $\tau$, and $\overline{\sigma}$ is disjoint from $N(\tau)$ otherwise.

Proof. Let $v$ be a point in $N(\tau)$, and let $\pi : \text{Trop}(U_\tau) \to N(\tau)$ be the continuous map that restricts to the canonical linear projections from $N(\gamma)$ onto $N(\tau)$ for $\gamma \preceq \tau$. If $v$ is not in $\sigma$, then the preimage under $\pi$ of $N(\tau) \setminus \sigma$ is an open neighborhood of $v$ that is disjoint from $\sigma$, so $v$ is not in $\overline{\sigma}$. Similarly, if $\sigma$ does not contain $\tau$ then $\pi^{-1}(N(\tau)) \setminus \sigma$ is an open neighborhood of $v$ that is disjoint from $\sigma$.

It remains to show that $\overline{\sigma} \cap N(\tau)$ contains $\sigma$ in the case where $\sigma$ contains $\tau$. Suppose $v$ is in $\sigma$, and let $w$ be a point in $\sigma$ that projects to $v$. Let $w'$ be a point in the relative interior of $\tau$. Then $w + \mathbb{R}_{>0}w'$ is a path in $\sigma$ whose limit is $v$, so $v$ is in $\overline{\sigma}$. □

3.2. Tropical subadditivity. Although not strictly necessary for the main results of the paper, it is helpful to know that codimension is subadditive for intersections of tropicalizations in $N_{\mathbb{R}}$, so $\text{Trop}(X)$ and $\text{Trop}(X')$ never intersect in less than the expected dimension. The proof is by a diagonal projection argument, similar to the proof of Lemma 3.1.2 below.

Proposition 3.2.1. Let $X$ and $X'$ be closed subschemes of pure codimension $j$ and $j'$, respectively, in $T$. If $\text{Trop}(X) \cap \text{Trop}(X')$ is nonempty then it has codimension at most $j + j'$ at every point.

Proof. Let $w$ be a point in $\text{Trop}(X) \cap \text{Trop}(X')$. Then, in a neighborhood of $w$, the intersection can be identified with a neighborhood of zero in $\text{Trop}(X_w) \cap \text{Trop}(X'_w)$. Therefore, replacing $X$ and $X'$ by their initial degenerations at $w$, we may assume the valuation is trivial, and it will suffice to show that the global codimension of $\text{Trop}(X) \cap \text{Trop}(X)$ is at most $j + j'$.

Suppose the valuation is trivial. Let $T'$ be the quotient of $T \times T$ by the diagonal subtorus, with $\pi : X \times X' \to T'$ the induced projection, and $p : \text{Trop}(X) \times \text{Trop}(X') \to N'_{\mathbb{R}}$ the tropicalization of $\pi$. Since $\text{Trop}(X)$ meets $\text{Trop}(X')$, the point zero is in the image of $p$, which is exactly the tropicalization of the closure of the image of $\pi$.

Let $y$ be a point in the image of $\pi$. The fiber $\pi^{-1}(y)$ has dimension at least $\dim X + \dim X' - \dim T'$ and, since the valuation is trivial, its tropicalization is contained in $p^{-1}(0)$. Since $p^{-1}(0)$ is naturally identified with $\text{Trop}(X) \cap \text{Trop}(X')$, it follows that the tropical intersection has dimension at least $\dim X' + \dim X - \dim T$, as required. □
3.3. Lower bounds on multiplicities. For the remainder of this section, we assume the valuation $\nu$ is trivial. Let $X$ and $X'$ be closed subschemes of pure codimension $j$ and $j'$ in $T$, respectively. After subdividing the tropicalizations, we choose a complete unimodular fan $\Sigma$ in $\mathbb{N}_\mathbb{R}$ such that each face of $\text{Trop}(X)$ and each face of $\text{Trop}(X')$ is a face of $\Sigma$. We write $\overline{X}$ and $\overline{X'}$ for the closures of $X$ and $X'$ in the smooth complete toric variety $Y(\Sigma)$.

Our goal is to prove the following version of Theorem 1.1 in the special case of the trivial valuation, with lower bounds on the multiplicities of the facets in $\text{Trop}(X \cap X')$. These lower bounds are extended to the general case in Section 5.

**Theorem 3.3.1.** Suppose $\nu$ is trivial and $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly. Then

$$\text{Trop}(X \cap X') = \text{Trop}(X) \cap \text{Trop}(X'),$$

and the multiplicity of any facet $\tau$ is bounded below by the tropical intersection multiplicity

$$m_{X \cap X'}(\tau) \geq i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')).$$

Furthermore, the tropical intersection multiplicity is equal to the weighted sum of algebraic intersection multiplicities

$$i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum_Z i(Z, X \cdot X'; Y(\Sigma)) m_Z(\tau),$$

where the sum is over components $Z$ of $X \cap X'$ whose tropicalizations contain $\tau$.

Given the compatibility of toric and stable tropical intersections in Proposition 2.7.7, the main step in the proof of Theorem 3.3.1 is showing that every component of $\overline{X} \cap \overline{X'}$ is the closure of a component of $X \cap X'$. This step can fail spectacularly when $\text{Trop}(X)$ and $\text{Trop}(X')$ do not meet properly. In such cases, $\overline{X} \cap \overline{X'}$ may contain components of larger than expected dimension, even if $X$ and $X'$ meet properly in $T$, and it is difficult to predict what $\text{Trop}(X \cap X')$ will look like.

**Proposition 3.3.2.** Suppose $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly, and let $\tau$ be a face of $\Sigma$. Then

1. The tropicalizations of $\overline{X} \cap O_\tau$ and $\overline{X'} \cap O_\tau$ meet properly in $N(\tau)$.
2. The subschemes $\overline{X} \cap V(\tau)$ and $\overline{X'} \cap V(\tau)$ meet properly in $V(\tau)$.
3. The closures $\overline{X}$ and $\overline{X'}$ meet properly in $Y(\Sigma)$, and every component of $\overline{X} \cap \overline{X'}$ is the closure of a component of $X \cap X'$.

**Proof.** First, if the tropicalizations of $\overline{X} \cap O_\tau$ and $\overline{X'} \cap O_\tau$ meet properly in $N(\tau)$, then the intersections themselves must meet properly in $O_\tau$, by part (1) of the foundational theorem in Section 2.2. If this holds for all cones $\sigma$ containing $\tau$, then $\overline{X} \cap V(\tau)$ meets $\overline{X'} \cap V(\tau)$ properly in $V(\tau)$. Therefore (1) implies (2).
Now, since $\text{Trop}(X)$ and $\text{Trop}(X')$ are subfans of $\Sigma$, the closures $\overline{X}$ and $\overline{X}'$ meet all orbits of $Y(\Sigma)$ properly (see Section 2.7). Hence, if (2) holds then every component of $\overline{X} \cap \overline{X}' \cap V(\tau)$ has codimension $j + j'$ in $V(\tau)$. In particular, if $O_{\tau}$ is not the dense torus $T$, then $V(\tau)$ does not contain a component of $\overline{X} \cap \overline{X}'$. If this holds for all $\tau$, then every component of $\overline{X} \cap \overline{X}'$ meets the dense torus $T$. This shows that (2) implies (3). We now prove (1).

The tropicalization of $\overline{X} \cap O_{\tau}$ is the intersection of the extended tropicalization $\text{Trop}(\overline{X})$ with $N(\tau)$ and, by Lemma 3.1.1, this extended tropicalization is the closure of $\text{Trop}(X)$. Therefore, by Lemma 3.1.2, $\text{Trop}(\overline{X} \cap O_{\tau})$ is the union of the projected faces $\sigma_{\tau}$ such that $\sigma$ is in $\text{Trop}(X)$ and contains $\tau$. Similarly, $\text{Trop}(\overline{X} \cap O_{\tau})'$ is the union of the projected faces $\sigma'_{\tau}$ such that $\sigma'$ is in $\text{Trop}(X')$ and contains $\tau$. Since the intersection of $\sigma_{\tau}$ and $\sigma'_{\tau}$ is exactly $(\sigma \cap \sigma')_{\tau}$, the codimension of $\sigma_{\tau} \cap \sigma'_{\tau}$ in $N(\tau)$ is equal to the codimension of $\sigma \cap \sigma'$ in $N_{\mathbb{R}}$. In particular, if $\text{Trop}(X)$ and $\text{Trop}(X')$ meet properly at $\tau$, then $\text{Trop}(\overline{X} \cap O_{\tau})$ and $\text{Trop}(\overline{X}' \cap O_{\tau})$ meet properly in $N(\tau)$, as required. □

The following lemma says that if $\text{Trop}(X)$ meets $\text{Trop}(X')$ properly then the support of their stable tropical intersection is equal to their set-theoretic intersection.

**Lemma 3.3.3.** Suppose $\text{Trop}(X)$ and $\text{Trop}(X')$ meet properly and let $\tau$ be a facet of their intersection. Then the tropical multiplicity $i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'))$ is strictly positive.

**Proof.** First, we reduce to the case where $X$ and $X'$ have complementary dimension. Recall that the tropical multiplicity $m(\sigma)$ of a facet $\sigma$ in $\text{Trop}(X)$ is equal to the algebraic intersection number $\deg(\overline{X} \cdot V(\sigma))$ in $Y(\Sigma)$, as discussed in Section 2.7. and the intersection number $\deg(\overline{X} \cdot \overline{X}' \cdot V(\tau))$ in $Y(\Sigma)$ is equal to the intersection number $\deg ((\overline{X} \cdot V(\tau)) \cdot (\overline{X}' \cdot V(\tau)))$ in $V(\tau)$ [Ful98, Example 8.1.10], because $V(\tau)$ is smooth. Because $\text{Trop}(X)$ and $\text{Trop}(X')$ are subfans of $\Sigma$, the closures $\overline{X}$ and $\overline{X}'$ in $Y(\Sigma)$ meet all torus orbits properly, and it follows that the tropical intersection multiplicity $i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'))$ is equal to the tropical intersection multiplicity at zero of $\text{Trop}(\overline{X} \cdot O_{\tau})$ and $\text{Trop}(\overline{X}' \cdot O_{\tau})$ inside $N(\tau)$. By Proposition 3.3.2 the intersection cycles $\overline{X} \cdot O_{\tau}$ and $\overline{X}' \cdot O_{\tau}$ have complementary dimension in $O_{\tau}$ and their tropicalizations meet properly in $N(\tau)$. The same is then true for each of the reduced components of $\overline{X} \cdot O_{\tau}$ and $\overline{X}' \cdot O_{\tau}$, and it suffices to prove the proposition in this case.

Assume $X$ and $X'$ have complementary dimension. Since their tropicalizations meet properly, by hypothesis, their intersection must be the single point zero. Consider the quotient $T'$ of $T \times T$ by its diagonal subtorus, and the induced projection

$$\pi : X \times X' \to T'.$$
Lifting Tropical Intersections

By Proposition 2.7.8, the tropical intersection number \( \text{Trop}(X) \cdot \text{Trop}(X') \) is equal to the length of \( X \cap tX' \) for a general point \( t \in T \), which is equal to the length of the general fiber of \( \pi \). In particular, to prove the proposition, it is enough to show that \( \pi \) is dominant. Now, since the valuation is trivial, the tropicalization of any fiber of \( \pi \) is contained in the preimage of zero under the induced projection

\[
\text{Trop}(X) \times \text{Trop}(X') \to N^r_x,
\]

which is the single point zero, by hypothesis. In particular, every nonempty fiber of \( \pi \) is zero-dimensional, and hence \( \pi \) is dominant, as required. \( \square \)

We can now easily prove the desired result.

Proof of Theorem 3.3.1. Let \( \tau \) be a facet of \( \text{Trop}(X) \cap \text{Trop}(X') \). By Propositions 2.7.7 and 3.3.2, the tropical intersection multiplicity \( i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) \) is a weighted sum over components of \( X \cap X' \)

\[
i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) = \sum_Z i(Z, X \cdot X'; T) m_Z(\tau).
\]

By Lemma 3.3.3 this multiplicity is strictly positive, so there is at least one component \( Z \) of \( X \cap X' \) such that \( \text{Trop}(Z) \) contains \( \tau \). This proves that \( \tau \) is contained in \( \text{Trop}(X \cap X') \), and hence \( \text{Trop}(X \cap X') \) is equal to \( \text{Trop}(X) \cap \text{Trop}(X') \), set-theoretically.

Finally, to see the inequality on multiplicities, recall that the multiplicity of \( \tau \) in \( \text{Trop}(X \cap X') \) is

\[
m_{X \cap X'}(\tau) = \sum_Z \text{length}_{O_{T, z}}(O_{X \cap X', z}) m_Z(\tau),
\]

by Lemma 2.7.2. The inequality \( m_{X \cap X'}(\tau) \geq i(\tau, \text{Trop}(X) \cdot \text{Trop}(X')) \) follows by comparing the two summation formulas term by term, because \( \text{length}_{O_{T, z}}(O_{X \cap X', z}) \) is at least as large as the intersection multiplicity \( i(Z, X \cdot X'; T) \) \cite{Ful98} Proposition 8.2. \( \square \)

4. Geometry over valuation rings of rank 1

In \cite{Nag66}, Nagata began extending certain results from dimension theory to non-noetherian rings. Here we continue in Nagata’s spirit with a view toward tropical geometry, focusing on valuation rings of rank 1 and showing that these rings have many of the pleasant properties of regular local rings.

Recall that a valuation ring of rank 1 is an integral domain \( R \) whose field of fractions \( K \) admits a nontrivial valuation \( \nu : K^* \to \mathbb{R} \) such that the nonzero elements of \( R \) are exactly the elements of \( K^* \) of nonnegative valuation. It is a local ring with exactly two prime ideals, the zero ideal and the maximal ideal. If \( K \) is algebraically closed or, more generally, if the valuation is not discrete, then \( R \) is not noetherian, because the maximal ideal is not finitely generated.

Throughout this section, \( R \) is a valuation ring of rank 1, with fraction field \( K \) and residue field \( k \). In this section only, we allow the possibility that \( K \)
is not algebraically closed, because the results of this section hold equally for nonclosed fields and the greater generality creates no additional difficulties. We fix 

\[ S = \text{Spec} \, R, \]

and use calligraphic notation for schemes over \( S \). If \( \mathcal{X} \) is a scheme over \( S \), we write \( \mathcal{X}_K = \mathcal{X} \times_S \text{Spec} \, K \) for the generic fiber and \( \mathcal{X}_k = \mathcal{X} \times_S \text{Spec} \, k \) for the special fiber.

A module is flat over \( R \) if and only if it is torsion-free \cite[Exercise 10.2]{Mat89}, so an integral scheme \( \mathcal{X} \) is flat over \( S \) if and only if it is dominant. Furthermore, a scheme that is flat and locally of finite type over an integral scheme is necessarily locally of finite presentation \cite[Theorem 3.4.6 and Corollary 3.4.7]{RG71}. In particular, if \( \mathcal{X} \) is an integral scheme that is surjective and locally of finite type over \( S \) then the special fiber \( \mathcal{X}_k \) is of pure dimension equal to the dimension of the generic fiber \( \mathcal{X}_K \). This follows from \cite[Theorem 12.1.1(i)]{Gro66}, applied to the generic point of each component of the special fiber. We will use these technical facts repeatedly throughout the section, without further mention.

Dimension theory over valuation rings of rank 1 involves some subtleties. For instance, if \( R \) is not noetherian then the formal power series ring \( R[[x]] \) has infinite Krull dimension \cite{Arn73}. Because dimensions are well-behaved under specialization over \( R \), such pathologies are always visible in at least one of the fibers. For \( \mathcal{X} = \text{Spec} \, R[[x]] \), the special fiber is \( \text{Spec} \, k[[x]] \), which is one dimensional, but \( R[[x]] \otimes K \) is the subring of \( K[[x]] \) consisting of formal power series whose coefficients have valuations bounded below. This ring, and hence the generic fiber of \( \text{Spec} \, R[[x]] \), is infinite dimensional. Nevertheless, for a scheme of finite type over \( S \), the generic fiber and special fiber are schemes of finite type over \( K \) and \( k \), respectively, and such pathologies do not occur.

Many of the results of this section have natural generalizations to more general base schemes. See Appendix B for details.

4.1. Subadditivity and lifting over valuation rings of rank 1. Serre famously proved that codimension is subadditive under intersections in regular schemes \cite[Theorem V.3]{Ser65}. In other words, for any irreducible closed subschemes \( X \) and \( X' \) of a regular scheme \( Y \), and any irreducible component \( Z \) of \( X \cap X' \), we have

\[ \text{codim}_Y Z \leq \text{codim}_Y X + \text{codim}_Y X'. \]

The same is then necessarily true for schemes smooth over \( Y \). We extend Serre’s theorem to smooth schemes over rank 1 valuation rings, as follows. Recall that we have fixed \( S = \text{Spec} \, R \), where \( R \) is a valuation ring of rank 1.

**Theorem 4.1.1.** Let \( \mathcal{Y} \) be smooth over \( S \). Then codimension is subadditive under intersection in \( \mathcal{Y} \).

In this respect, valuation rings of rank 1 behave like regular local rings.

**Remark** 4.1.2. Subadditivity of codimension is often used to deform points in families using dimension counting arguments. Such techniques are essential,
for instance, in the theory of limit linear series developed by Eisenbud and Harris [EH86]. Here, we use subadditivity of codimension to lift intersection points from the special fiber to the generic fiber in schemes of finite type over valuation rings of rank 1.

As an application of Theorem 4.1.1 we prove the following.

**Theorem 4.1.3.** Let $Y$ be smooth over $S$ with closed subschemes $X$ and $X'$ of pure codimension $j$ and $j'$, respectively. Suppose the special fibers $X_k$ and $X'_k$ intersect in codimension $j + j'$ at a point $x$ in $Y_k$. Then

1. There is a point in $X_K \cap X'_K$ specializing to $x$.
2. If $x$ is closed then there is a closed point in $X_K \cap X'_K$ specializing to $x$.

More generally, if $k(x)$ denotes the residue field of $x$, there is a point $x' \in X_K \cap X'_K$ specializing to $x$ and satisfying

$$\text{trdeg } k(x')/K = \text{trdeg } k(x)/k.$$

In Section 4.4 we also prove a principle of continuity for intersection multiplicities in families over $S$.

**Remark 4.1.4.** The theorem reduces easily to the case where $X$ and $X'$ are reduced and irreducible and then, using subadditivity, it is not difficult to show that both must meet the generic fiber $Y_K$ and are therefore flat over $S$. Our methods also give a more general lifting theorem for intersections of flat subschemes over an arbitrary base scheme (Theorem 4.3), even when subadditivity fails. Here we proceed through subadditivity because it eliminates the need for a flatness hypothesis and makes the lifting arguments particularly transparent, especially for those familiar with similar arguments over regular local rings.

4.2. A principal ideal theorem. Recall that Krull’s principal ideal theorem, translated into geometric terms, says that every component of a Cartier divisor on a noetherian scheme has codimension 1. Here we prove the following generalization to valuation rings of rank 1.

**Theorem 4.2.1.** Let $X$ be of finite type over $S$, and let $Z$ be a locally principal closed subscheme of $X$. Then every irreducible component of $Z$ has codimension at most 1 in each component of $X$ that contains it.

The same is not true for valuation rings that are not of rank 1. If $A$ is such a ring then Spec $A$ has principal subschemes of codimension greater than 1. A key step in the proof of the theorem is the following technical proposition, which we prove by noetherian approximation.

---

The assumption that schemes are of finite type over $S$ is crucial for the main results of this section. In the tropical setting, if $\nu$ is nontrivial and $w$ is not in $N_G$, then closed points of $X_w$ never lift to closed points of $X$. However, this does not contradict Theorem 4.2.5 because in this case $X^w$ is not of finite type. See Appendix A.
Proposition 4.2.2. Let \( \mathcal{X} \) be irreducible, locally of finite type, and flat over \( S \). Suppose that \( D \) is a locally principal closed subscheme in \( \mathcal{X} \) that does not meet the generic fiber \( \mathcal{X}_K \). Then every irreducible component of \( D_k \) is an irreducible component of \( \mathcal{X}_k \).

Proof. Since \( \mathcal{X} \) is flat and locally of finite type over \( S \), it is locally of finite presentation over \( S \). The question is local, so we may assume that \( \mathcal{X} \) is affine, and in particular of finite presentation over \( S \). Therefore, there exists a finitely generated subring \( R' \subset R \), with models \( X' \) and \( D' \) over \( S' = \text{Spec} R' \) of \( \mathcal{X} \) and \( D \), respectively. Then \( S' \) is irreducible by construction, and we may assume \( X' \) is irreducible as well.

Let \( s' \) be the image in \( S' \) of the closed point in \( S \). Since \( \mathcal{X}_K \) and \( \mathcal{X}_k \) are both pure of the same dimension \( d \), the fibers of \( X' \) over the generic point and \( s' \) are also pure of dimension \( d \). Similarly, \( D_k \) is pure of dimension \( d \) if and only if \( D'_s \) is, so to prove the proposition it is enough to show that \( D'_s \) is pure of dimension \( d \).

Let \( Z \) be a component of \( D' \) that meets the fiber over \( s' \). We will show that \( Z_s \) has pure dimension \( d \). Let \( s'' \) be the image in \( S' \) of the generic point of \( Z \). Then \( s'' \) is a specialization of the generic point of \( S' \) and specializes to \( s' \), so upper semicontinuity of fiber dimension [Gro66, Theorem 13.1.3] implies that \( X'_{s''} \) has pure dimension \( d \). We claim that \( Z_{s''} \) is a component of \( X'_{s''} \). To see this, note that \( s'' \) is not the generic point of \( S' \), since \( D \) does not meet the generic fiber of \( \mathcal{X} \), and hence every component of \( X'_{s''} \) has codimension at most \( 1 \) in \( X' \). Since \( X' \) is noetherian, Krull’s principal ideal theorem says that every component of \( D' \) has codimension at most \( 1 \) in \( X' \), and hence \( Z_{s''} \) is a component of \( X'_{s''} \), as claimed. In particular, \( Z_{s''} \) has pure dimension \( d \). Since \( s'' \) specializes to \( s' \) and \( X'_{s''} \) has pure dimension \( d \), it follows by upper semicontinuity that \( Z_{s'} \) has pure dimension \( d \), as required.

The following two lemmas are special cases of a more general altitude formula over valuation rings of finite rank [Nag66, Theorem 2]. These codimension formulas are used in the proof of the principal ideal theorem, and again in the proof of subadditivity of codimension over valuation rings of rank 1. We include proofs for the reader’s convenience.

Lemma 4.2.3. Suppose \( \mathcal{X} \) is irreducible, finite type, and flat over \( S \) with \( Z \subset \mathcal{X}_k \) an irreducible closed subset of the special fiber. Then

\[
\text{codim}_X Z = \text{codim}_{\mathcal{X}_k} Z + 1.
\]

Proof. A maximal chain of irreducible closed subsets between \( Z \) and \( \mathcal{X}_k \) can be extended by adding \( \mathcal{X} \) at the end, so \( \text{codim}_X Z \) is at least \( \text{codim}_{\mathcal{X}_k} Z + 1 \).

We now show that \( \text{codim}_X Z \) is at most \( \text{codim}_{\mathcal{X}_k} Z + 1 \).

If \( W \subset W' \) is a strict inclusion of irreducible closed subsets of \( \mathcal{X} \) that meet the special fiber then the dimension of \( W_k \) is less than or equal to the dimension of \( W'_k \). This inequality is strict if \( W \) and \( W' \) are both contained in the special fiber. Similarly, if \( W \) and \( W' \) both meet the generic fiber then \( \dim W_K \) is less than \( \dim W'_K \), and the dimensions of the special fibers are equal to the...
dimensions of the respective generic fibers, by flatness. Therefore, if \( \dim W_k \) is equal to \( \dim W'_k \) then \( W \) is contained in the special fiber and \( W' \) is not. This can happen at most once in any chain of inclusions, so any chain between \( Z \) and \( X \) has length at most \( \dim X_k - \dim Z + 1 \), as required. \( \square \)

**Lemma 4.2.4.** Suppose \( X \) is irreducible, finite type, and flat over \( S \), and let \( Z \subseteq Z' \) be irreducible closed subsets. Then

\[
\operatorname{codim}_X Z = \operatorname{codim}_X Z' + \operatorname{codim}_Z Z.
\]

**Proof.** If \( Z \) meets the generic fiber of \( X \) then this is a classical formula for codimension of varieties over \( K \). Suppose \( Z \) is contained in the special fiber. If \( Z' \) meets the generic fiber then \( \operatorname{codim}_X Z' = \dim X_K - \dim Z'_K \), and \( \operatorname{codim}_Z Z = \dim Z'_k - \dim Z + 1 \), by Lemma 4.2.3. Now \( \dim X_K \) and \( \dim Z'_K \) are equal to \( \dim X_k \) and \( \dim Z'_k \), respectively, so adding these two equations gives

\[
\operatorname{codim}_X Z' + \operatorname{codim}_Z Z = \dim X_k - \dim Z + 1,
\]

and Lemma 4.2.3 says that the right hand side is equal to \( \operatorname{codim}_X Z \). The proof in the case where \( Z' \) is contained in the special fiber is similar. \( \square \)

We now prove the principal ideal theorem over valuation rings of rank 1.

**Proof of Theorem 4.2.1.** We may assume that \( X \) is integral, and since the statement is local about the generic points of \( Z \), we may assume that \( Z \) is irreducible. If \( X \) is supported in the special fiber, the theorem reduces to the classical principal ideal theorem over \( k \). Otherwise \( X \) is dominant, and hence flat, over \( S \). If \( Z \) meets the generic fiber \( X_K \), then the theorem follows from the classical principal ideal theorem for \( X_K \). On the other hand, if \( Z \) is contained in the special fiber, then it must be a union of components of the special fiber, by Proposition 4.2.2, and hence has codimension 1 in \( X \), by Lemma 4.2.3. \( \square \)

We apply the principal ideal theorem to prove the following result on lifting closed points in the special fiber to closed points in the generic fiber. In fact, we prove a more general result, for points of arbitrary transcendence degree. Our argument is in the spirit of Katz’s proof of [Kat09, Lemma 4.15].

**Theorem 4.2.5.** Let \( X' \) be an irreducible scheme locally of finite type over \( S \), and let \( x \) be a closed point of the special fiber \( X_k \). If \( x \) is in the closure of \( X_K \) then the set of closed points \( x' \) in \( X_K \) specializing to \( x \) is Zariski dense in \( X_K \). More generally, if \( x \) is not necessarily closed in \( X_k \), and \( k(x) \) denotes the residue field of \( x \), we can choose \( x' \) to satisfy the identity

\[
\operatorname{trdeg} k(x')/K = \operatorname{trdeg} k(x)/k,
\]

and again the choices of \( x' \) are Zariski dense in \( X_K \).

**Proof.** Note that the statement for closed points is a special case of the statement involving transcendence degrees. We may assume \( X \) is integral and in particular flat over \( S \), and also affine.
By hypothesis, $x$ is a specialization of the generic point of $X$. Observe that given $x' \in X_K$ specializing to $x$, the closure of $x'$ is flat over $S$, so we obtain the inequality $\text{trdeg} k(x')/K \geq \text{trdeg} k(x)/k$. Now, if $\dim X_K = \text{trdeg} k(x)/k$, then we may take $x'$ to be the generic point of $X_K$. We thus proceed by induction on $d := \dim X_K - \text{trdeg} k(x)/k$.

Suppose now $d > 0$, and note that this implies that $x$ is not the generic point of any component of $X_k$. Let $W$ be a closed subset properly contained in $X_K$; by affineness, we can choose a regular function $f$ on $X$ that vanishes at $x$, but not on any component of $W \cup X_k$. Then let $D \subset X$ be the principal subscheme cut out by $f$. Passing to a smaller neighborhood of $x$, if necessary, we may assume every component of $D$ contains $x$. By Proposition 4.2.2, some component $Z$ of $D$ meets the generic fiber, and hence $\dim Z_K - \text{trdeg} k(x)/k = d - 1$. By induction, $Z_K$ contains a point $x'$ specializing to $x$, not contained in $W$, and with $\text{trdeg} k(x')/K = \text{trdeg} k(x)/k$. We conclude the desired statement. \hfill \Box

\textbf{Remark 4.2.6.} For the initial degeneration of a closed subscheme of a torus $T$ over $K$ associated to a weight vector $w \in N_G$, in the special case where $x$ is closed, Theorem 4.2.5 says that every point in $X_w(k)$ lifts to a point in $X(K)$, and the set of such lifts is Zariski dense. In particular, the theorem gives an algebraic proof of surjectivity of tropicalization, along the lines suggested by Speyer and Sturmfels in [SS04], as well as a proof of the density of tropical fibers stated as Theorem 4.1 and Corollary 4.2 in [Pay09b]. A gap in the proof of the former paper is explained in a footnote on the first page of the latter. The proof of Theorem 4.1 in the latter also contains a serious error, discovered by W. Buczynska and F. Sottile, which is explained and corrected in [Pay12].

\textbf{Remark 4.2.7.} When applied to non-closed points, Theorem 4.2.5 says that every closed subvariety of $X_w$ is a component of the special fiber of the closure in $X^w$ of some closed subvariety of $X$. So, at least in this weak sense, every curve in $X_w$ lifts to a curve in $X$, every surface in $X_w$ lifts to a surface in $X$, and so on.

\section{4.3. Proofs of Subadditivity and Lifting.} We now use the principal ideal theorem to prove subadditivity of codimension under intersection and deduce a lifting theorem for proper intersections, in smooth schemes over a valuation ring of rank 1. Our proof follows the classical argument for smooth varieties, which is simpler than Serre’s proof for regular schemes.

\textbf{Remark 4.3.1.} Codimension is not subadditive under intersection in smooth schemes over valuation rings of rank greater than 1, as shown by the following example. Nevertheless, this failure of subadditivity can be understood and controlled, and proper intersections in special fibers still lift to more general fibers over arbitrary valuation rings and, more generally, for flat families of subschemes in a smooth scheme over an arbitrary base. See Appendix B.

\textbf{Example 4.3.2.} Let $A$ be a valuation ring of finite rank $r$ greater than 1, and let $a$ be an element of $A$ that generates an ideal of height $r$. Then $A[x]$ has Krull dimension $r + 1$, by [Nag66, Theorem 2]. The ideals of $A[x]$ generated
by $x$ and $x - a$ each have height 1, but the ideal $(x, x - a) = (x, a)$ has height $r + 1$, which is greater than 2.

Our proof of Theorem 4.1.1 involves a reduction to the diagonal and requires the following lemma on dimensions of fiber products over $S$.

**Lemma 4.3.3.** Let $\mathcal{Y}$ be irreducible and finite type over $S$, and let $\mathcal{X}$ and $\mathcal{X}'$ be irreducible closed subschemes. Then for every irreducible component $Z$ of $\mathcal{X} \times_S \mathcal{X}'$,

$$\text{codim}_{\mathcal{Y} \times_S \mathcal{Y}} Z \leq \text{codim}\, \mathcal{X} + \text{codim}\, \mathcal{X}'$$

Furthermore, the inequality is strict if and only if $\mathcal{Y}$ is dominant over $S$ and $\mathcal{X}$ and $\mathcal{X}'$ are both contained in the special fiber.

**Proof.** If $\mathcal{X}$ and $\mathcal{X}'$ both meet the generic fiber then they are flat over $S$. In this case, $Z$ must also meet the generic fiber, and the proposition holds with equality, by classical dimension theory over $K$. Similarly, if $\mathcal{Y}$ is not dominant over $S$, then the proposition holds with equality by dimension theory over $k$. Suppose $\mathcal{Y}$ is dominant and $\mathcal{X}$ is contained in the special fiber. Then $Z$ is also contained in the special fiber. If, furthermore, $\mathcal{X}'$ is contained in the special fiber, then $Z$ has dimension $\dim \mathcal{X} + \dim \mathcal{X}'$. Therefore, by Lemma 4.2.3,

$$\text{codim}_{\mathcal{Y} \times_S \mathcal{Y}} Z = 2 \dim \mathcal{Y}_K - \dim \mathcal{X} - \dim \mathcal{X}' + 1.$$

The right hand side is equal to $\text{codim}\, \mathcal{X} + \text{codim}\, \mathcal{X}' - 1$, so the inequality is strict by exactly one in this case. A similar argument shows that the proposition holds with equality if $\mathcal{X}'$ meets the generic fiber. \qed

We will prove subadditivity of codimension using the previous proposition and a reduction to the diagonal.

**Lemma 4.3.4.** If $\mathcal{Y}$ is smooth over $S$ then the diagonal $\Delta$ in $\mathcal{Y} \times_S \mathcal{Y}$ is a local complete intersection subscheme.

Here, by local complete intersection we mean that the number of local generators for $I_\Delta$ is equal to the codimension.

**Proof.** First note that the diagonal morphism is locally of finite presentation, by [Gr64, Corollary 1.4.3.1]. The lemma follows, since a locally finite presentation immersion of a smooth scheme in another smooth scheme over an arbitrary base is a local complete intersection. See Proposition 7 of Section 2.2 in [BLR90]. \qed

We now proceed with the proof of subadditivity of codimension and lifting of proper intersections in the special fiber, over valuation rings of rank 1.

**Proof of Theorem 4.1.1.** The intersection $\mathcal{X} \cap \mathcal{X}'$ can be realized as the intersection of $\mathcal{X} \times_S \mathcal{X}'$ with the diagonal in $\mathcal{Y} \times_S \mathcal{Y}'$. Now, the codimension of any component $Z$ of $\mathcal{X} \times_S \mathcal{X}'$ is at most

$$\text{codim}_{\mathcal{Y} \times_S \mathcal{Y}} Z \leq \text{codim}\, \mathcal{X} + \text{codim}\, \mathcal{X}'$$
by Lemma 4.3.3. Then the principal ideal theorem (Theorem 4.2.1) and Lemma 4.2.4 together imply that codimension can only decrease when intersecting with a local complete intersection subscheme of \( Y \times_S Y \). Lemma 4.3.4 says that the diagonal is a local complete intersection, and the theorem follows.

\[ \square \]

**Proof of Theorem 4.1.3.** Let \( Z \) be a component of \( X \cap X' \) that contains \( x \). By Theorem 4.1.1,

\[ \text{codim}_Y Z \leq \text{codim}_Y X + \text{codim}_Y X' + 1, \]

by Lemma 1.2.3 so \( Z \) must meet the generic fiber. Therefore, the generic point of \( Z_K \) is a point of \( X_K \cap X'_K \), specializing to \( x \). If \( x \) is closed in its fiber, we can then find a closed point of \( Z_K \) specializing to \( x \), by Theorem 4.2.5 and similarly for the assertion on transcendence degrees.

\[ \square \]

4.4. Intersection multiplicities over valuation rings of rank 1. The principle of continuity says that intersection numbers are constant when cycles vary in flat families. See [Ful98, Section 10.2] for a precise statement and proof when the base is a smooth variety. For applications to tropical lifting with multiplicities, we need to apply a principle of continuity over the spectrum \( S \) of a possibly non-Noetherian valuation ring of rank 1. Lacking a suitable reference, we include a proof.

**Definition 4.4.1.** Suppose \( Y \) is smooth over a field \( k \), and let \( X \) and \( X' \) be closed subschemes of \( Y \) whose intersection \( X \cap X' \) is finite. Then the intersection number \( i(X \cdot X'; Y) \) of \( X \) and \( X' \) in \( Y \) is

\[ \dim Y \sum_{i=0}^\dim Y (-1)^i \dim_k \Tor^1_{\mathcal{O}_Y}(\mathcal{O}_X, \mathcal{O}_{X'}). \]

In other words, the intersection number is the sum of the local intersection multiplicities at the finitely many points of \( X \cap X' \), weighted by degrees of extension fields,

\[ i(X \cdot X'; Y) = \sum_{P \in X \cap X'} [k(P) : k] i_P(P, X \cdot X'; Y). \]

While we are primarily interested in the case where \( X \) and \( X' \) have complementary dimension, so the finiteness of \( X \cap X' \) means that \( X \) and \( X' \) meet properly in \( Y \), this hypothesis is not technically necessary, since the local intersection multiplicities vanish when the intersection is not proper [Ser65, Theorem V.C.1].

**Theorem 4.4.2.** Let \( Y \) be smooth and quasiprojective over \( S \), and let \( X \) and \( X' \) be closed subschemes of \( Y \) that are flat over \( S \). If \( X \cap X' \) is finite over \( S \) then

\[ i(X_K \cdot X'_K; Y_K) = i(X_k \cdot X'_k; Y_k). \]
In other words, intersection numbers are invariant under specialization over $S$. We now give a direct proof of this equality, by first establishing coherence properties for the structures sheaves of these schemes and then using free resolutions to compute the Tor groups. An alternative approach, using noetherian approximation and specialization properties of intersection theory over a noetherian base, is sketched in Remark 4.4.4.

In general, the structure sheaf of a non-noetherian scheme is not necessarily coherent. The following proposition asserts that such pathologies do not occur on the schemes we are considering.

**Proposition 4.4.3.** Let $X$ be locally of finite presentation over $S$. Then $\mathcal{O}_X$ is coherent.

**Proof.** We first claim that $\mathcal{O}_X$ is coherent in the special case where $X$ is the affine space $\text{Spec} R[t_1, \ldots, t_n]$. Since the question is local, it is enough to show that for any affine subset $U$ of $X$, and any homomorphism $f: \mathcal{O}_X|_U \to \mathcal{O}_X|_U$, the kernel of $f$ over $U$ is finitely generated. Now, the image of $f$ is finitely generated, and is the quasicoherent ideal sheaf $\tilde{I}$ associated to some ideal $I$ in $\mathcal{O}_X(U)$. The ideal $I$ is torsion-free and hence flat over $S$, so it is finitely presented by [RG71, Theorem 3.4.6]. Therefore, by [Mat89, Theorem 2.6], the kernel of the given presentation $\mathcal{O}_X(U)^m \to I$ is finitely generated, which proves the claim.

For the general case, since coherence is local, we may again assume that $X$ is affine, so $X = \text{Spec} A[t_1, \ldots, t_n]/I$ for some finitely generated ideal $I$. The same argument as in the special case above shows that $\tilde{I}$ is coherent on $\text{Spec} R[t_1, \ldots, t_n]$, and hence $\mathcal{O}_X$ is coherent [Gro60, Chapter 0, 5.3.10].

**Proof of Theorem 4.4.2.** Since $Y$ is quasiprojective and $X \cap X'$ is finite over $S$, there is an affine open subset of $Y$ containing the intersection, and hence we may assume $Y$ is affine. Now $\mathcal{O}_Y$ is coherent, by Proposition 4.4.3 and $\mathcal{O}_X$ and $\mathcal{O}_{X'}$, being flat and finitely generated, are finitely presented and hence coherent as $\mathcal{O}_Y$-modules. Let $P_\bullet$ be a resolution of $\mathcal{O}_X$ by free $\mathcal{O}_Y$-modules of finite rank. Then, since $\mathcal{O}_X$ is flat over $S$, the restrictions $P_\bullet \otimes K$ and $P_\bullet \otimes k$ to the generic and special fibers remain exact, giving free resolutions of $\mathcal{O}_{X_K}$ and $\mathcal{O}_{X'_k}$, respectively. Therefore, not only does the homology of $\mathcal{O}_X$ compute $\text{Tor}_Y(X, X')$, but also the homology of the base changes $Q_\bullet \otimes K$ and $Q_\bullet \otimes k$ computes $\text{Tor}_{Y_K}(X'_K, X'_K)$ and $\text{Tor}_{Y_K}(X_K, X'_K)$, respectively.

Now, $\text{Tor}_Y(X, X')$ is coherent, and supported on $X \cap X'$ [Gro63, 6.5.1]. It follows from [Gro63, Proposition 1.4.7] that the push forward of a quasicoherent, finitely presented module under a finite morphism of finite presentation is still quasicoherent and finitely presented. Applying this to $\pi: X \cap X' \to S$ it follows that the push forward $\pi_! \mathcal{O}_{X'}$ is coherent, and since $\pi$ is affine,
this push forward can be computed as the homology of the complex
\[ L \]  
As above, since \( O_X \) is flat over \( S \), the homology of \( L \otimes K \) and \( L \otimes k \) compute \( \text{Tor}^Y_k(X_K, X'_K) \) and \( \text{Tor}^Y_k(X_k, X'_k) \), respectively. Note also that since \( O_{X'} \) is flat over \( S \), the terms of \( Q \) and hence \( L \) are flat \( O_S \)-modules.
Since the homology of \( L \) is coherent, there is a quasi-isomorphic bounded below complex \( M \) of free \( O_S \)-modules of finite rank, and since \( L \) is flat over \( S \), the restrictions \( M \otimes K \) and \( M \otimes k \) are quasi-isomorphic to \( L \otimes K \) and \( L \otimes k \), respectively [Gro61b, Chapter 0, Proposition 11.9.1; see also Remark 11.9.3]. We claim that the homology of \( M \) vanishes in high degree: indeed, the homology of \( M \otimes k \) computes \( \text{Tor} \) on the smooth \( Y_k \), so vanishes in high degree, and the claim then follows from flatness of \( M \) and Nakayama’s lemma. Thus, we can truncate the complex, replacing some \( M_i \) by the image of \( M_{i+1} \), which is coherent and torsion-free and hence free of finite rank. In particular, we may assume that \( M \) is also bounded above. It is then clear that
\[ i(X_s \cdot X'_s, Y_s) = \sum_i (-1)^i \text{rk} M_i, \]
for \( s \) equal to either the generic or closed point of \( S \), and the theorem follows.

Remark 4.4.4. Theorem 4.4.2 can also be proved over an arbitrary base scheme as follows. It is easy to see that intersection numbers are invariant under extension of the base field, so the result behaves well under base change. Passing to the closure of the more general point, and then taking an affine neighborhood around the special point, we reduce to the case where the base is affine and irreducible. This ensures that \( X \) and \( X' \) are finitely presented over the base \( S \), because they are flat and finite type, and then we can proceed by noetherian approximation. Say the affine base is \( \text{Spec} A \). Then there is a finitely generated subalgebra \( A_0 \) of \( A \) over which \( X, X', \) and \( Y \) and all of the relevant morphisms are defined, and all can be chosen so that the relevant geometric properties are preserved, including that the models of \( X \) and \( X' \) are flat [Gro66 Sections 11 and 12], and the model of \( Y \) is quasiprojective [Gro66 Theorem 8.10.5] and smooth [Gro67 Section 17.7]. In particular, we may assume the base is noetherian. By [Gro61a Proposition 7.1.9] we can thus reduce to the case of a DVR, and the theorem follows from the well-known fact that intersection numbers are preserved by specialization over a DVR [Ful98 Section 20.3].

In the geometric case that we are interested in, where the fraction field \( K \) is algebraically closed and hence the residue field \( k \) is algebraically closed as well, we apply Theorem 4.4.2 on intersection numbers to get the following result on individual intersection multiplicities along components of the intersection of the special fibers. Note that this result is of a local nature, and holds for arbitrary expected dimension for the intersection.
Theorem 4.4.5. Assume \( K \) is algebraically closed. Let \( \mathcal{Y} \) be smooth over \( S \), and let \( \mathcal{X} \) and \( \mathcal{X}' \) be closed subschemes that are flat over \( S \). Suppose \( \mathcal{X}_k \) and \( \mathcal{X}'_k \) meet properly along a component \( Z \) of their intersection. Then
\[
i(Z, \mathcal{X}_k \cdot \mathcal{X}'_k; \mathcal{Y}_k) = \sum_{\tilde{Z}} m(Z, \tilde{Z}) \cdot i(\tilde{Z}, \mathcal{X}_K \cdot \mathcal{X}'_K; \mathcal{Y}_K),
\]
where the sum is over irreducible components \( \tilde{Z} \) of \( \mathcal{X}_K \cap \mathcal{X}'_K \) whose closures contain \( Z \), and \( m(Z, \tilde{Z}) \) is the multiplicity of \( Z \) in the special fiber of the closure of \( \tilde{Z} \) inside \( \mathcal{Y} \).

Proof. We first prove the special case where \( \mathcal{X} \) and \( \mathcal{X}' \) have complementary dimension. Suppose \( Z \) is a point. We claim that there is an affine open neighborhood \( U \) of \( Z \) such that \( \mathcal{X} \cap \mathcal{X}' \cap U \) is finite over \( S \) and has special fiber exactly \( Z \). By upper semicontinuity of fiber dimension \([\text{Gro}66, \text{Theorem 13.1.3}]\), the union \( \mathcal{W}_1 \) of the positive dimensional components of \( \mathcal{X}_K \cap \mathcal{X}'_K \) and \( \mathcal{X}_k \cap \mathcal{X}'_k \) is closed in \( \mathcal{Y} \). The intersection of \( \mathcal{X}_K \) and \( \mathcal{X}'_K \) in the complement of \( \mathcal{W}_1 \) is a finite set of \( K \)-points. Let \( \mathcal{W}_2 \) be the closure of those points in this set that do not specialize to \( Z \). We claim that any affine neighborhood of \( Z \) contained in \( \mathcal{Y} \setminus (\mathcal{W}_1 \cup \mathcal{W}_2) \) is the desired neighborhood. Now \( \mathcal{X} \cap \mathcal{X}' \cap \mathcal{U} \) is separated, quasifinite over \( S \) and has special fiber \( Z \), by construction, and it is locally of finite presentation, since \( \mathcal{X} \) and \( \mathcal{X}' \) are locally of finite type and flat, and hence locally of finite presentation. By \([\text{Gro}66, \text{Theorem 8.11.1}]\), to show that this intersection is finite it only remains to check that it is proper over \( S \). The generic fiber consists of finitely many \( K \)-points, each of which extends to an \( R \)-point, and one can check that this implies the valuative criterion for universal closedness \([\text{Gro}61a, \text{Theorem 7.3.8}]\), which proves the claim. Now, note that \( m(\tilde{Z}, Z) = 1 \) for every \( \tilde{Z} \), since each \( \tilde{Z} \) is a \( K \)-point whose closure is a section. The required equality of intersection numbers then follows immediately from Theorem 4.4.2.

We now prove the general case, where the intersection may have positive dimension, by reducing to the case of a zero-dimensional intersection. Since the statement is local on \( \mathcal{Y} \), we may assume \( \mathcal{Y} \) is affine, that \( Z \) is the only component of \( \mathcal{X}_k \cap \mathcal{X}'_k \), and that every component of \( \mathcal{X}_K \cap \mathcal{X}'_K \) contains \( Z \) in its closure. Let \( \tilde{Z}_1, \ldots, \tilde{Z}_m \) be the irreducible components of \( \mathcal{X}_K \cap \mathcal{X}'_K \). Localizing further, we may also assume that \( Z \) and the \( \tilde{Z}_i \) are all smooth (although we cannot assume that the closures of the \( \tilde{Z}_i \) are smooth, as \( Z \) may appear with multiplicity greater than 1).

Now, let \( \mathcal{L}_k \) be a general linear subspace of complementary dimension in the special fiber, so \( \mathcal{L}_k \) meets \( Z \) transversely at finitely many points. Choose a general lift \( \mathcal{L} \) of \( \mathcal{L}_k \) to \( S \); by the Zariski density of Theorem 1.4.2.3 applied to the Grassmannian over \( S \), the generic fiber \( \mathcal{L}_K \) meets each component of \( \mathcal{X}_K \cap \mathcal{X}'_K \) transversely, at isolated points. After further localizing, we may assume \( \mathcal{L}_k \) meets \( Z \) at a single point \( z \), and every point \( \tilde{z} \) of \( \mathcal{X}_K \cap \mathcal{X}'_K \cap \mathcal{L}_K \) specializes to \( z \). Since \( \mathcal{L} \) is a complete intersection, applying \([\text{Ful}98, \text{Example 8.1.10}]\) in the
special fiber, we have
\[ i(Z, \mathcal{X}_k \cdot \mathcal{X}_k'; Y_k) = i(z, (\mathcal{X}_k \cap L_k) \cdot (\mathcal{X}_k' \cap L_k); L_k). \]

Now, note that an inductive application of [Gro66, Proposition 11.3.7] implies that \( \mathcal{X} \cap L \) and \( \mathcal{X}' \cap L \) remain flat over \( S \) so, by the zero-dimensional case treated above, the right hand side is equal to
\[ \sum_{\tilde{z}} i(\tilde{z}, (\mathcal{X}_K \cap L_K) \cdot (\mathcal{X}_K' \cap L_K); L_K). \]

If \( \tilde{Z}_i \) is the component of \( \mathcal{X}_K \cap \mathcal{X}_K' \) containing \( \tilde{z} \), then a similar argument in the generic fiber gives
\[ i(\tilde{z}, (\mathcal{X}_K \cap L_K) \cdot (\mathcal{X}_K' \cap L_K); L_K) = i(\tilde{Z}_i, \mathcal{X}_K \cdot \mathcal{X}_K'; Y_K). \]

The theorem follows since, by the zero-dimensional case above, the multiplicity \( m(\tilde{Z}_i, Z) \) is the number of points \( \tilde{z} \) in \( \tilde{Z}_i \cap L \) specializing to \( z \).

\[ \square \]

**Corollary 4.4.6.** Let \( X \) be a pure-dimensional closed subscheme of \( T \). Then \( \text{Trop}(X) \) is equal to the tropicalization of the fundamental cycle \( \text{Trop}([X]) \).

**Proof.** We may assume the valuation is nontrivial. It is clear that the tropicalizations agree set-theoretically, since both are the closure of the image of \( X(K) \).

To see that the multiplicities agree, let \( w \) be a point in the relative interior of a facet of \( \text{Trop}(X) \), and apply Theorem 4.4.5 in the special case where \( Y \) and \( X' \) are both equal to \( T^w \).

\[ \square \]

5. **Lifting tropical intersections with multiplicities**

We now use the results of Sections 3 and 4 to prove the main tropical lifting theorems, both as stated in the introduction and in refined forms with multiplicities. We also prove generalizations to intersections of three or more subschemes and discuss weaker lifting results when the tropicalizations do not meet properly.

5.1. **Intersections of two subschemes.** Let \( Y \) be a closed subvariety of \( T \), and let \( X \) and \( X' \) be closed subschemes of pure codimension \( j \) and \( j' \), respectively, in \( Y \).

**Proof of Theorem 5.1.** Suppose \( \text{Trop}(X) \) meets \( \text{Trop}(X') \) properly at a simple point \( w \) of \( \text{Trop}(Y) \). Let \( K|K \) be an extension of valued fields such that \( w \in N_G \), where \( G \) is the value group of \( G \). Then the tropicalizations after base change \( \text{Trop}(\tilde{X}) \) and \( \text{Trop}(\tilde{X}') \) meet properly at \( w \), and Theorem 4.4.4 implies furthermore that \( X_w \) meets \( X'_w \) properly at a smooth point of \( Y_w \) if and only if \( \tilde{X}_w \) meets \( \tilde{X}'_w \) properly at a smooth point of \( \tilde{Y}_w \). Therefore, after an extension of valued fields, we may assume \( w \in N_G \).

The initial degeneration \( Y_w \) is a torus torsor containing \( X_w \) and \( X'_w \), and the tropicalizations \( \text{Trop}(X_w) \) and \( \text{Trop}(X'_w) \) with respect to the trivial valuation...
Lifting Tropical Intersections

are the stars of \( w \) in \( \text{Trop}(X) \) and \( \text{Trop}(X') \), respectively, and hence meet properly in the vector space \( \text{Trop}(Y_w) \). Theorem 3.3.1 then says that

\[
\text{Trop}(X_w \cap X'_w) = \text{Trop}(X_w) \cap \text{Trop}(X'_w).
\]

In particular, \( X_w \cap X'_w \) is nonempty of codimension \( j + j' \), and the theorem follows, since \( Y_w \) is smooth. \( \Box \)

**Proof of Theorem 1.4.** Suppose \( X_w \) meets \( X'_w \) properly at a smooth point \( x \) of \( Y_w \). After extending the valued field we may assume the valuation is nontrivial and \( w \in N_G \). In this case, the integral model \( Y_w \) is of finite type over \( \text{Spec} R \), by Proposition \ref{prop:finite-type}. We can then pass to an open neighborhood of \( x \) in \( Y_w \) in which the special fiber is smooth and apply Theorem 4.1.3 to deduce that there is a point of \( X \cap X' \) specializing to \( x \). Therefore \( x \) is contained in \( (X \cap X')_w \). \( \Box \)

As noted in the introduction, Theorem 1.2 follows immediately from Theorems 1.3 and 4.1.3, and Theorem 1.1 is the special case where \( Y \) is the torus \( T \). So this concludes the proof of the theorems stated in the introduction.

We now state and prove a refined version of Theorem 1.2 with multiplicities.

\[ m_{X \cap X'}(\tau) \geq i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'); \text{Trop}(Y)), \]

and both are strictly positive. Furthermore, the tropical intersection multiplicity is equal to the weighted sum of algebraic intersection multiplicities

\[ i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'); \text{Trop}(Y)) = \sum_Z i(Z, X \cdot X'; Y) m_Z(\tau), \]

where the sum is over components \( Z \) of \( X \cap X' \) whose tropicalizations contain \( \tau \).

Although the global intersection product \( X \cdot X' \) need not be defined, the intersection multiplicities \( i(Z, X \cdot X'; Y) \) (as defined in terms of Tor in Section 2.5) appearing in the statement of Theorems 5.1.1 and Theorem 5.2.3 below, are nonetheless well-defined. Indeed, for every component \( Z \) of \( X \cap X' \) whose tropicalization contains \( \tau \), we have that \( Y \) must be smooth on a non-empty open subset that intersects \( Z \) by the simple point hypothesis, and because \( \text{Trop}(X) \)
Brian Osserman and Sam Payne

is assumed to meet Trop(X′) properly along τ, it also follows that X meets X′ properly along Z.

Proof. First, by Theorem 1.2, the face τ is contained in Trop(X ∩ X′). We prove the identity between the tropical intersection multiplicity and the weighted sum of algebraic intersection multiplicities and then deduce the inequality for m_{X∩X′}(τ), as follows. Let w be a point in τ that is a simple point of Trop(Y).

After extending the valued field, we may assume w ∈ NG. Then the tropical intersection multiplicity along τ is equal to the local tropical intersection multiplicity at w

\[ i(\tau, \text{Trop}(X) \cdot \text{Trop}(X′) ; \text{Trop}(Y)) = i(\tau_w, \text{Trop}(X_w) \cdot \text{Trop}(X′_w) ; \text{Trop}(Y_w)), \]

where \( \tau_w = \mathbb{R}_{>0}(\tau - w) \), as in Section 2.7. Then, since Y_w is a torus torsor, Theorem 3.3.1 says that this local tropical intersection multiplicity is given by

\[ i(\tau_w, \text{Trop}(X_w) \cdot \text{Trop}(X′_w) ; \text{Trop}(Y_w)) = \sum_{Z_0} i(Z_0, X_w \cdot X′_w ; Y_w) m_{Z_0}(\tau_w), \]

where the sum is over components Z_0 of X_w ∩ X′_w whose tropicalizations contain \( \tau_w \). By Theorem 4.4.5 for each such Z_0,

\[ i(Z_0, X_w \cdot X′_w ; Y_w) = \sum_Z m(Z, Z_0) i(Z, X \cdot X′ ; Y), \]

where the sum is over components Z of X ∩ X′ and m(Z, Z_0) is the multiplicity of Z_0 in the special fiber of the closure of Z in Y_w. Combining these identities with the results of Section 2.7 gives the required equality, since

\[ m(Z, Z_0) = \sum_{Z_0} m(Z_0, Z) m_{Z_0}(\tau_w), \]

where the sum ranges over components Z_0 of the special fiber of the closure of Z.

The inequality follows immediately from this equality, since

\[ m_{X∩X′}(\tau) = \sum_Z \text{length}(O_{Z,X∩X′}) m_Z(\tau), \]

by Corollary 4.4.6 and \[ \text{length}(O_{Z,X∩X′}) \geq i(Z, X \cdot X′ ; Y) \] for each Z [Pit98 Proposition 7.1].

If Trop(X) meets Trop(X′) properly in N_R, then part (2) of Theorem 5.1.1 has a particularly simple statement equating the tropicalization of the refined intersection cycle with the stable tropical intersection.

**Corollary 5.1.2.** Suppose Trop(X) meets Trop(X′) properly in N_R. Then

\[ \text{Trop}(X \cdot X′) = \text{Trop}(X) \cdot \text{Trop}(X′). \]

We also note that the inequality in Theorem 5.1.1 can be replaced by an equality if X and X′ are smooth, or mildly singular.

**Corollary 5.1.3.** Under the hypotheses of Theorem 5.1.1 if X and X′ are Cohen-Macaulay then

\[ m_{X∩X′}(\tau) = i(\tau, \text{Trop}(X) \cdot \text{Trop}(X′) ; \text{Trop}(Y)). \]
Proof. If $X$ and $X'$ are Cohen-Macaulay, then the length of the scheme-theoretic intersection of $X$ and $X'$ along each component $Z$ of expected dimension is equal to the intersection multiplicity $i(Z, X \cdot X'; Y)$ [Ful98, Example 8.2.7]. The result then follows from the equality in Theorem 5.1.1, since

$$m_{X \cap X'}(\tau) = \sum_{\mathcal{Z}} \text{length}(\mathcal{O}_{\mathcal{Z}, X \cap X'}) m_{\mathcal{Z}}(\tau),$$

by Lemma 2.7.2, where the sum is over components $\mathcal{Z}$ of $X \cap X'$ such that $\text{Trop}(\mathcal{Z})$ contains $\tau$. $\square$

5.2. Intersections of three or more subschemes. In applications, and particularly in the context of enumerative geometry, one frequently wants to intersect more than two subschemes. The algebraic intersection product of several closed subschemes $X_1 \cdots X_r$ may be treated either by induction from results on intersection of pairs or by a standard reduction to the diagonal argument. For the reduction to the diagonal, one uses the facts that $X_1 \cap \cdots \cap X_r$ is canonically identified with the intersection $X_1 \times \cdots \times X_r \cap \Delta$ in $Y^r$, where $\Delta$ is the diagonal subscheme, and that $X_1 \times \cdots \times X_r \cdot \Delta$ is the push forward of $X_1 \cdots X_r$ under the diagonal embedding.

Definition 5.2.1. Let $X_1, \ldots, X_r$ be closed subschemes in $T$, of pure codimension $j_1, \ldots, j_r$, respectively. Then the stable tropical intersection $\text{Trop}(X_1) \cdots \text{Trop}(X_r)$ is the iterated pairwise stable tropical intersection

$$\text{Trop}(X_1) \cdots \text{Trop}(X_r) = (\cdots ((\text{Trop}(X_1) \cdot \text{Trop}(X_2)) \cdot \text{Trop}(X_3)) \cdots \text{Trop}(X_r)).$$

The following proposition shows that stable tropical intersections for three or more closed subschemes can be computed as a pairwise intersection with the tropicalization of the diagonal. In particular, the stable tropical intersection is independent of the order of the factors.

Proposition 5.2.2. The stable tropical intersection $\text{Trop}(X_1 \times \cdots \times X_r) \cdot \text{Trop}(\Delta)$ is the image of $\text{Trop}(X_1) \cdots \text{Trop}(X_r)$ under the diagonal embedding of $N^r_\mathbb{R}$ in $N^r_\mathbb{R}$.

Proof. Let $\Sigma$ be a complete unimodular fan that contains $\text{Trop}(X_1), \ldots, \text{Trop}(X_r)$ as subfans. By Proposition 2.7.6 the stable tropical intersections $\text{Trop}(X_1 \times \cdots \times X_r) \cdot \text{Trop}(\Delta)$ and $\text{Trop}(X_1) \cdots \text{Trop}(X_r)$ correspond to the products of Minkowski weights $\omega_{X_1} \cdots \omega_{X_r}$ and $\omega_{X_1} \cdots \omega_{X_r}$, on $\Sigma'$ and $\Sigma$, respectively. These products of Minkowski weights are equal to $\omega_{X_1} \cdots \omega_{X_r}$ and $\omega_{X_1} \cdots \omega_{X_r}$ by the identification of rings of Minkowski weights with Chow rings, discussed in Section 2.5. The proposition follows, since $X_1 \times \cdots \times X_r \cdot \Delta$ is the push forward of $X_1 \cdots X_r$ under the diagonal embedding. $\square$

As in the case of pairwise intersections, when $X_1, \ldots, X_r$ are subschemes of pure codimension $j_1, \ldots, j_r$ in an irreducible variety $Y$, we define the stable tropical intersection multiplicity along a face $\tau$ of codimension $j_1 + \cdots + j_r$ in $\text{Trop}(Y)$, provided that $\tau$ contains a simple point $w$ of $\text{Trop}(Y)$, as the multiplicity of $\tau_w$.
in the stable tropical intersection of the stars of $w$ in $\text{Trop}(X_1), \ldots, \text{Trop}(X_r)$ inside the star of $w$ in $\text{Trop}(Y)$.

We now generalize Theorem 5.1.1 to intersections of several closed subschemes by reducing to the case of a pairwise intersection with the diagonal in $Y^r$.

**Theorem 5.2.3.** Let $X_1, \ldots, X_r$ be closed subschemes of pure codimension $j_1, \ldots, j_r$ in $Y$, respectively. Suppose $\tau$ is a facet of $\text{Trop}(X_1) \cap \cdots \cap \text{Trop}(X_r)$ of codimension $j_1 + \cdots + j_r$ in $\text{Trop}(Y)$ that contains a simple point of $\text{Trop}(Y)$. Then the tropicalization $\text{Trop}(X_1 \cap \cdots \cap X_r)$ contains $\tau$ with multiplicity bounded below by the tropical intersection multiplicity
\[ m_{X_1 \cap \cdots \cap X_r}(\tau) \geq i(\tau, \text{Trop}(X_1) \cdots \text{Trop}(X_r); \text{Trop}(Y)), \]
and both are strictly positive. Furthermore, the tropical intersection multiplicity is equal to the weighted sum of algebraic intersection multiplicities
\[ i(\tau,\text{Trop}(X_1) \cdots \text{Trop}(X_r);\text{Trop}(Y)) = \sum_Z i(Z,X_1 \cdots X_r;Y)m_Z(\tau), \]
where the sum is over components of $X_1 \cap \cdots \cap X_r$ such that $\text{Trop}(Z)$ contains $\tau$.

**Proof.** Let $\tau$ be a facet of $\text{Trop}(X_1) \cap \cdots \cap \text{Trop}(X_r)$ of codimension $j_1 + \cdots + j_r$ in $\text{Trop}(Y)$ that contains a simple point $w$ of $\text{Trop}(Y)$. Then the image of $\tau$ under the diagonal embedding $\delta$ of $\text{Trop}(Y)$ in $\text{Trop}(Y^r)$ is a facet of $\text{Trop}(X_1 \times \cdots \times X_r) \cap \text{Trop}(\Delta)$ of codimension $(r-1)\dim(Y) + j_1 + \cdots + j_r$, in $\text{Trop}(Y^r)$, where $\Delta$ is the diagonal subscheme in $Y^r$, containing a simple point of $\text{Trop}(Y^r)$. By Theorem 5.1.1, $\delta(\tau)$ is a face of $\text{Trop}(X_1 \times \cdots \times X_r \cap \Delta)$. Furthermore, the multiplicity of $\delta(\tau)$ in the stable tropical intersection $\text{Trop}(X_1 \times \cdots \times X_r \cap \text{Trop}(\Delta))$ inside $\text{Trop}(Y^r)$ is strictly positive, equal to
\[ \sum_Z i(Z,X_1 \times \cdots \times X_r;\Delta; Y^r)m_Z(\delta(\tau)), \]
and less than or equal to $m_{X_1 \times \cdots \times X_r \cap \Delta}(\delta(\tau))$. Now $X_1 \times \cdots \times X_r \cap \Delta$ is canonically identified with $X_1 \cap \cdots \cap X_r$, and both the tropical multiplicities and the local intersection multiplicities agree. In other words, we have
\[ i(Z,X_1 \times \cdots \times X_r;\Delta; Y^r) = i(Z,X_1 \cdots X_r;Y) \]
and
\[ m_Z(\delta(\tau)) = m_Z(\tau). \]

The theorem then follows, by Proposition 5.2.2. \qed

The following application of Theorem 5.2.3, giving a formula for counting points in zero-dimensional complete intersections, has been applied by Rabinoff to construct canonical subgroups of abelian varieties over $p$-adic fields, via a suitable generalization for power series [Rab12a, Rab12b].

Let $f_i = \sum a_i(u)x^u$ be an equation defining $X_i$, with $P_i = \text{conv}\{u|a_i \text{ is nonzero}\}$ its Newton polytope. Projecting the lower faces of the lifted Newton polytope $\text{conv}\{\{u,\nu(a_i(u))\}\}$ in $M_\mathbb{R} \times \mathbb{R}$ gives the Newton
subdivision of $P_i$. This Newton subdivision is dual to $\text{Trop}(X_i)$, in the sense that there is a natural polyhedral structure on $\text{Trop}(X_i)$ whose faces are in order-reversing bijection with the positive dimensional faces of the Newton subdivision. A face $\tau$ of $\text{Trop}(X_i)$ corresponds to the convex hull of the lattice points $u$ such that $a_i(u)x^n$ is a monomial of minimal $w$-weight, for $w$ in the relative interior of $\tau$.

Our formula is phrased in terms of mixed volumes of faces of the Newton subdivision. Recall that, for lattice polytopes $Q_1, \ldots, Q_n$ in $M_\mathbb{R} \cong \mathbb{R}^n$, the euclidean volume of the Minkowski sum $b_1Q_1 + \cdots + b_nQ_n$ is a polynomial of degree $n$ in $b_1, \ldots, b_n$, and the mixed volume $V(Q_1, \ldots, Q_n)$ is the coefficient of $b_1 \cdots b_n$ divided by $n!$. If $\Sigma$ is the smallest common refinement of the inner normal fans of the $Q_i$, then each $Q_i$ corresponds to a nef line bundle $L_i$ on the toric variety $Y(\Sigma)$, and the mixed volume is equal to the intersection number, divided by $n!$,

$$V(Q_1, \ldots, Q_n) = (c_1(L_1) \cdots c_1(L_n))/n!.$$ 

See [Ful93, p. 116] for further details on mixed volumes and their relation to toric intersection theory and [KK12, Section 4] for generalizations to arbitrary projective varieties via Newton-Okounkov bodies. Mixed volume formulas for tropical stable complete intersections are standard in the case of the trivial valuation. The earliest reference we know of relating mixed volumes to tropical complete intersections for a nontrivial (discrete) valuation is due to Smirnov [Smi96].

**Corollary 5.2.4.** Let $X_1, \ldots, X_n$ be hypersurfaces in $T$, and suppose $w$ is an isolated point in $\text{Trop}(X_1) \cap \cdots \cap \text{Trop}(X_n)$. Let $Q_i$ be the face of the Newton subdivision corresponding to the minimal face of $\text{Trop}(X_i)$ that contains $w$. Then the number of points in $X_1 \cap \cdots \cap X_n$ with tropicalization $w$, counted with multiplicities, is exactly $n!V(Q_1, \ldots, Q_n)$.

**Proof.** Fix a complete unimodular fan $\Sigma$ in $N_\mathbb{R}$ such that, for $i = 1, \ldots, n$, every face of $\text{Star}_w \text{Trop}(X_i)$ is a union of faces of $\Sigma$. Since $\text{Star}_w \text{Trop}(X_i)$ is the codimension 1 skeleton of the possibly degenerate inner normal fan of $Q_i$, it follows that $Q_i$ corresponds to a nef line bundle $L_i$ on $Y(\Sigma)$. Furthermore, the Minkowski weight of codimension 1 on $\Sigma$ given by the tropical multiplicities on $\text{Star}_w \text{Trop}(X_i)$ corresponds to $c_1(L_i)$. It follows, by the compatibility of toric and stable multiplicity the tropical intersection multiplicity

$$i(w, \text{Trop}(X_1) \cdots \text{Trop}(X_n)) = (c_1(L_1) \cdots c_1(L_n)),$$

and the latter is $n!V(Q_1, \ldots, Q_n)$. By Theorem 5.2.3, this tropical intersection multiplicity is equal to the number of points in $X_1 \cap \cdots \cap X_n$ with tropicalization $w$, counted with multiplicities, as required. \[\square\]

---

There is a minor misstatement in the definition of mixed volumes, in the text in between displayed formulas (1) and (2) of [Ful93, p. 116]. The mixed volume is the coefficient of $v_1 \cdots v_n$ divided by $n!$, not multiplied by $n!$. The displayed formulas (1), (2), and (3) are correct. Formulas (1) and (2) uniquely determine the mixed volumes of rational polytopes, as does (3), which also characterizes mixed volumes of arbitrary convex bodies.
Remark 5.2.5. In Corollary 5.2.4 the multiplicities on the points $x$ in $X_1 \cap \cdots \cap X_n$ with tropicalization $w$ are equal to the lengths of the scheme-theoretic intersection of $X_1, \ldots, X_n$ along $x$, as in Corollary 5.1.3 since complete intersections are Cohen-Macaulay.

5.3. Non-proper intersections. Our main tropical lifting results require the tropicalizations to meet properly. Nevertheless, our results on lifting from the special fiber to the generic fiber of $Y^w$, such as Theorem [14] still yield nontrivial statements for nonproper tropical intersections. In many cases, such as Example 6.2 the initial degenerations meet properly even when the tropicalizations do not.

Proposition 5.3.1. Suppose that for each $w \in \text{Trop}(X) \cap \text{Trop}(X')$, we have that $w$ is smooth and $X_w$ meets $X'_w$ properly in $Y_w$. Then $X$ meets $X'$ properly in $Y$. Furthermore, the set of $w$ such that $X_w \cap X'_w$ is nonempty is either empty or the underlying set of a polyhedral complex of pure codimension $j + j'$ in $\text{Trop}(Y)$.

Proof. If $w$ is in $\text{Trop}(X \cap X')$, then $X_w \cap X'_w$. Conversely, if $X_w$ meets $X'_w$ properly at some smooth point $x$ of $Y_w$ then $x$ is contained in $(X \cap X')_w$, by Theorem 1.3 and hence $w$ is in $\text{Trop}(X \cap X')$. Therefore, the hypotheses of the proposition ensure that the set of $w$ such that $X_w$ meets $X'_w$ is exactly $\text{Trop}(X \cap X')$, and $(X \cap X')_w$ is equal to $X_w \cap X'_w$ for all $w$. If $X_w \cap X'_w$ is nonempty then it has pure codimension $j + j'$ in $Y_w$. It follows that $X \cap X'$ has pure dimension $j + j'$ in $Y$, and hence $\text{Trop}(X \cap X')$ is a polyhedral complex of pure codimension $j + j'$ in $\text{Trop}(Y)$, as required. □

In the special case where $Y$ is the ambient torus $T$, one can say even more. If all initial degenerations meet properly, then the set of weight vectors where the intersection is nonempty is exactly the stable tropical intersection, as was suggested to us by J. Rau.

Proposition 5.3.2. Suppose $X_w$ meets $X'_w$ properly in $T_w$ for all $w$. Then the set of $w \in N_\mathbb{R}$ such that $X_w \cap X'_w$ is nonempty is exactly the underlying set of the stable tropical intersection $\text{Trop}(X) \cdot \text{Trop}(X')$.

Proof. Let $\Sigma$ be a complete unimodular fan that contains the stars of $w$ in $\text{Trop}(X)$ and in $\text{Trop}(X')$ as subfans. First we claim that, for any $w$ in $N_\mathbb{R}$, the closures $\overline{X}_w$ and $\overline{X}'_w$ meet properly in $Y(\Sigma)$ and, furthermore, $\overline{X}_w \cap O_\sigma$ and $\overline{X}'_w \cap O_\sigma$ meet properly in $O_\sigma$ for every $\sigma$ in $\Sigma$. Indeed, after choosing an extension of valued fields such that $w$ is rational over the value group and subdividing $\Sigma$, we may assume that it contains tropical fans, in the sense of [Lew07], for $X_w$ and $X'_w$ as subfans. Then, for $v \in N_G$ in the relative interior of $\sigma$ and $\epsilon \in G$ sufficiently small and positive, the initial degenerations $X_{w + \epsilon v}$ and $X'_{w + \epsilon v}$ agree with the initial degenerations of $X_w$ and $X'_w$, respectively, for the weight vector $v$ [Gub12 Corollary 10.12]. The images of these initial degenerations under projection to $O_\sigma$ are identified with $\overline{X}_w \cap O_\sigma$ and $\overline{X}'_w \cap O_\sigma$, up to simultaneous translation in $O_\sigma$ [Gub12 Remark 12.7]. Since $X_{w + \epsilon v}$ and
$X_{w+tv}$ meet properly in $T_{w+tv}$, it follows that $\overline{X}_w \cap O_\sigma$ and $\overline{X}_w \cap O_\sigma$ meet properly in $O_\sigma$, as claimed.

Since $\overline{X}_w \cap O_\sigma$ and $\overline{X}_w \cap O_\sigma$ meet properly in $O_\sigma$ for every $\sigma$ in $\Sigma$, Proposition 2.7.7 says that a cone $\tau_w$ of codimension $j + j'$ in $\Sigma$ appears in the tropicalization of $X_w \cdot X'_w$ with multiplicity equal to the stable tropical intersection multiplicity $i(\tau_w, \text{Trop}(X_w) \cdot \text{Trop}(X'_w))$ which agrees with the stable tropical intersection multiplicity $i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'))$, by Proposition 2.7.6.

In particular, $X_w \cap X'_w$ is nonempty if and only if $w$ is contained in the stable tropical intersection $\text{Trop}(X) \cdot \text{Trop}(X')$. □

For closed subschemes of the torus $T$, when a tropical intersection is not proper we can translate the subschemes by a suitable element of $T(K)$ so that the initial degenerations meet properly, without changing the tropicalizations. The following theorem extends Proposition 2.7.8 to the general case, where the valuation may not be trivial, and gives a geometric meaning to the stable tropical intersection, as the tropicalization of an intersection with a translate by a general point $t$ such that $\text{Trop}(t)$ is zero.

If $t$ is in $T(K)$ then the tropicalization of the translate $tX$ is the translate of $\text{Trop}(X)$ by the vector $\text{Trop}(t)$ in $N_G$. In particular, the tropicalization is invariant under translation by points $t$ such that $\text{Trop}(t)$ is zero. The set of such points is Zariski dense in $T(K)$ [Pay09, Corollary 4.2] (see also [Pay12, Remark 2]), but not Zariski open if the valuation is nontrivial. Nevertheless, we say that a property holds for a general point $t$ such that $\text{Trop}(t)$ is zero if there is a Zariski open subset $U_0$ of the initial degeneration $T_0$ such that the property holds for all $t$ with $t_0 \in U_0$. This set is again Zariski dense in $T(K)$.

**Theorem 5.3.3.** Let $X$ and $X'$ be pure-dimensional closed subschemes of $T$. Then, for a general point $t$ such that $\text{Trop}(t)$ is zero,

$$\text{Trop}(X \cap tX') = \text{Trop}(X) \cdot \text{Trop}(X').$$

**Proof.** If the valuation is trivial then the theorem is given by Proposition 2.7.8. Assume the valuation is nontrivial. Let $\tau$ be a face of $\text{Trop}(X) \cap \text{Trop}(X')$, and let $w \in N_G$ be a point in $\tau$. The initial degeneration $(tX')_w$ is the translate of $X'_w$ by $t_0$. Since $t_0$ is general in $T_0$, Proposition 2.7.8 says that

$$\text{Trop}(X_w \cap (tX')_w) = \text{Trop}(X_w) \cdot \text{Trop}(X'_w).$$

In particular, if $w$ is not in the stable tropical intersection then the initial degenerations $X_w$ and $(tX')_w$ are disjoint, so $w$ is not in $\text{Trop}(X \cap tX')$. On the other hand, if $w$ is in the stable intersection then $X_w$ meets $(tX')_w$ properly in $T_w$, by Proposition 2.7.8 and all points of $X_w \cap (tX')_w$ lift to the generic fiber $X \cap tX'$, by Theorem 4.1.3. Note that for $w$ and $w'$ in the relative interior of $\tau$, because the isomorphisms $X_w \cong X_{w'}$ and $tX'_w \cong tX'_w$ can be simultaneously induced by a single isomorphism $T_w \cong T_{w'}$, if $X_w$ meets $tX'_w$, then $X_{w'}$ likewise meets $tX'_w$ properly. Since there are only finitely many faces of $\text{Trop}(X) \cap \text{Trop}(X')$, the point $t$ can be chosen sufficiently general so that this holds in every face.
This shows that the underlying sets of $\text{Trop}(X \cap tX')$ and $\text{Trop}(X) \cdot \text{Trop}(X')$ are equal. Now, let $\tau$ be a facet of $\text{Trop}(X) \cdot \text{Trop}(X')$ and let $w \in N_G$ be a point in the relative interior of $\tau$. The tropical intersection multiplicity along $\tau$ is equal to the local tropical intersection multiplicity at $w$

\[ i(\tau, \text{Trop}(X) \cdot \text{Trop}(X'); \text{Trop}(T)) = i(\tau, \text{Trop}(X_w) \cdot \text{Trop}(X'_w); \text{Trop}(T_w)), \]

and, by Proposition 2.7.8 the right hand side is equal to $m_{X_w \cap tX'_w}(\tau_w)$. Applying Theorem 4.4.5 to the intersection of $X^w$ and $(tX')^w$ in $T^w$, as in the proof of Theorem 5.1.1 then shows that $m_{X_w \cap tX'_w}(\tau_w)$ is equal to $m_{X \cdot tX'}(\tau)$. As in the proof of Proposition 2.7.8, the genericity of $t$ guarantees that the cycle $X \cdot tX'$ is equal to the fundamental cycle of $X \cap tX'$. Therefore, $m_{X \cdot tX'}(\tau)$ is equal to $m_{X \cap tX'}(\tau)$, and the theorem follows. 

6. Examples

Here we give a number of examples illustrating our tropical lifting theorems and the necessity of their hypotheses. The first example involves tropicalizations that meet properly, but not necessarily in the interiors of maximal faces.

\textbf{Example 6.1. }Inside $Y = (K^*)^2$, let $X$ and $X'$ be given by $y = x + 1$ and $y = ax^2$, respectively, with $a \in K^*$. We consider three cases, according to whether or not $\nu(a)$ is zero, and its sign if it is nonzero.

If $\nu(a)$ is positive then $\text{Trop}(X)$ meets $\text{Trop}(X')$ at two points, each with multiplicity 1. In this case, Theorem 5.1.1 says that $X$ meets $X'$ at two points, each with multiplicity 1, and one of these intersection points lies over each of the points of $\text{Trop}(X) \cap \text{Trop}(X')$. It is also straightforward to check this directly. If $\nu(a)$ is negative, then $\text{Trop}(X)$ meets $\text{Trop}(X')$ at a single point, but with tropical intersection multiplicity 2. In this case, Theorem 5.1.1 says that $X$ meets $X'$ at either a single point with multiplicity 2, or at two points of
multiplicity 1, and one can check that the intersection is always two points of multiplicity 1. In both of these cases, the nonemptiness of \( X \cap X' \) also follows from the transverse tropical lifting result of [BJS+07], since the tropicalizations meet properly in the interiors of maximal faces.

Suppose \( \nu(a) \) is zero. Then \( \text{Trop}(X) \) and \( \text{Trop}(X') \) meet at a single point with tropical multiplicity 2, but the intersection is in a nonmaximal face of \( \text{Trop}(X) \), so transverse lifting results do not apply. Nevertheless, Theorem 5.1.1 still says that \( X \) and \( X' \) meet at either a single point with multiplicity 2, or at two points of multiplicity 1. Either possibility can occur; the algebraic intersection is a single point of multiplicity 2 when the characteristic is not 2 and \( a = -1/4 \), and two points of multiplicity 1 otherwise.

In the following example, the tropicalizations meet nonproperly along a positive dimensional set that does not contain the the tropicalization of any curve.

**Example 6.2.** Inside \( Y = (K^*)^2 \), let \( X \) and \( X' \) be given by \( y = x + 1 \) and \( y = ax + b \), respectively, with \( a \) and \( b \) in \( K^* \). Assume \( a \) and \( b \) are not both 1, so the closures of \( X \) and \( X' \) are distinct lines in \( K^2 \). In particular, \( X \) and \( X' \) intersect in at most one point.

Suppose \( \nu(a) \) is zero and \( \nu(b) \) is positive. Then \( \text{Trop}(X) \) and \( \text{Trop}(X') \) intersect nonproperly, along the ray \( R_{\leq 0} \cdot (1, 1) \).

If \( a = 1 \), then the closures of \( X \) and \( X' \) are parallel lines in \( K^2 \), so none of the tropical intersection points lift.

Suppose \( a \) is not 1. Then the unique algebraic intersection point is

\[
X \cap X' = ((1 - b)/(a - 1), (a - b)/(a - 1)),
\]

and the unique point of \( \text{Trop}(X) \cap \text{Trop}(X') \) that lifts is \((\nu(a - 1), -\nu(a - 1))\).

For a suitable choice of \( a \) congruent to 1 modulo \( m \), any nonzero \( G \)-rational point in the tropical intersection can lift. For such \( a \), the initial degenerations \( X_w \) and \( X'_w \) coincide for all nonzero \( w \) in \( \text{Trop}(X) \cap \text{Trop}(X') \), and are disjoint otherwise. In particular, none of the initial degenerations meet properly. On
the other hand, if \( a \) is not congruent to 1 modulo \( \mathfrak{m} \), then the initial degenerations \( X_w \) and \( X'_w \) meet transversely at a single point for \( w = (0,0) \), and are disjoint otherwise. In this case \((0,0)\) is the unique tropical intersection point that lifts, as it must be by Theorem 1.4. Note that, even though \( \text{Trop}(X \cap X') \) and the stable tropical intersection are both zero-dimensional, neither is necessarily contained in the other.

In the remaining examples, we assume the characteristic of \( K \) is not 2 and consider tropicalizations of skew lines inside a smooth quadric surface. These examples demonstrate the necessity of requiring the point of proper intersection to be a simple point of \( \text{Trop}(Y) \) or a smooth point of \( Y_w \), in Theorems 1.2, 1.3, and 1.4.

**Example 6.3.** Let \( Y \) be the surface in \((K^*)^3\) given by
\[
z^2 + xy + x + y = 0.
\]
Then \( Y \) contains the curves \( X \) and \( X' \) given by \( x + 1 = z - 1 = 0 \) and \( x + 1 = z + 1 = 0 \), respectively. Now, \( \text{Trop}(X) \) and \( \text{Trop}(X') \) still meet properly at \( w = (0,0,0) \), as shown.

However, this tropical intersection point does not lift because the closures of \( X \) and \( X' \) are skew lines in \( K^3 \). This is consistent with Theorems 1.2 and 1.3 because \( w \) is not in the relative interior of a facet, and the initial degenerations \( X_w \) and \( X'_w \) are disjoint. The closures of \( X_w \) and \( X'_w \) in \( k^3 \) are skew lines in the closure of \( Y_w \), which is a smooth quadric surface.

**Example 6.4.** Let \( a \in K^* \) be an element of positive valuation, and let \( Y' \) be the surface given by
\[
z^2 - 1 + a(xy + x + y + 1) = 0,
\]
and let $X$ and $X'$ be as in Example 6.3. Then $X$ and $X'$ are contained in $Y'$, and their tropicalizations still meet properly in $\text{Trop}(Y')$ at the origin $w$, which is in the relative interior of a facet $\sigma$ of $\text{Trop}(Y')$, as shown.

The tropical intersection point $w$ does not lift to $X \cap X'$, but this is still consistent with Theorems 1.2 and 1.3 because the multiplicity of the facet $\sigma$ is 2, and hence $w$ is not a simple point of $\text{Trop}(Y')$. The initial degeneration $Y''_w$ has two disjoint components, each of which contains the initial degeneration of one of the curves.

In particular, this tropical intersection point does not lift even to the intersection of the initial degenerations.
Example 6.5. Let \( a \in K^* \) be an element of positive valuation, with \( Y'' \) be the surface in \( (K^*)^3 \) given by
\[
(x + 1)(y + 1) + (x + z)(y + z + a) = 0.
\]
Let \( X \) again be as in Example 6.3 and let \( X'' \) be the curve given by \( y + 1 = z - 1 + a = 0 \). Once again, \( \text{Trop}(X) \) and \( \text{Trop}(X'') \) meet properly at \( w = (0, 0, 0) \). Furthermore, the initial degenerations \( X_w \) and \( X''_w \) meet properly at a single point in \( Y''_w \).

This intersection point lifts to the initial degenerations but not to the general fiber, because the closures of \( X \) and \( X'' \) are skew lines in \( K^3 \). This is still consistent with Theorem 1.4 because \( Y''_w \) is a cone, and \( X_w \) meets \( X''_w \) at the singular point.

**Appendix A. Initial degenerations, value groups, and base change**

Here we study how initial degenerations behave with respect to arbitrary extensions of valued fields. These basic results are used throughout the paper to reduce our main lifting theorems to the case where \( w \) is in \( N_G \), by extending the ground field.

Let \( M_{G,w} \) be the maximal sublattice of \( M \) on which \( w \) is \( G \)-rational. In other words,
\[
M_{G,w} = \{ u \in M \mid \langle u, w \rangle \text{ is in } G \}.
\]
Since \( K \) is algebraically closed, the value group \( G \) is divisible, and hence \( M_{G,w} \) is saturated in \( M \). If the weight of a monomial \( ax^u \) is zero, then \( \langle u, w \rangle = -\nu(a) \), and hence \( u \) is in \( M_{G,w} \). In particular, \( M_{G,w} \) contains all exponents of monomials that restrict to nonzero functions on \( T_w \), and \( T_w \) is a torsor over the torus associated to \( M_{G,w} \).
Proposition A.1. Suppose the valuation is nontrivial. Then the integral model $T^w$ is of finite type over $\text{Spec} \mathcal{R}$ if and only if $w$ is in $N_G$. Furthermore, if $w$ is in $N_G$, then $T^w$ is of finite presentation over $\text{Spec} \mathcal{R}$.

Proof. Suppose $w$ is in $N_G$. Let $u_1, \ldots, u_r$ be a basis for $M$, and choose $a_1, \ldots, a_r$ in $K^*$ such that $\nu(a_i) = -(u_i, w)$. Then $R[M]^w$ is generated over $R$ by
\[
\{a_1x^{u_1}, (a_1x^{u_1})^{-1}, \ldots, a_rx^{u_r}, (a_rx^{u_r})^{-1}\},
\]
and hence is of finite type. Furthermore, the relations are generated by
\[
\{1 - a_ix^{u_i}, (a_ix^{u_i})^{-1}\},
\]
so $R[M]^w$ is of finite presentation.

For the converse, suppose $w$ is not in $N_G$. Then, $M_{G,w}$ is a proper sublattice of $M$, and hence the special fiber $T^w$ has dimension strictly less than the dimension of $T$. Since $T^w$ is irreducible and fiber dimension is semicontinuous in irreducible families of finite type, it follows that $T^w$ is not of finite type. \qed

Remark A.2. Suppose the valuation is trivial, and let $S_w$ be the set of lattice points $u \in M$ such that $(u, w) \geq 0$. Then $S_w$ is a subsemigroup of $M$, and $R[M]^w$ is naturally identified with the semigroup ring $K[S_w]$. The semigroup $S_w$ is finitely generated if and only if the ray spanned by $w$ has rational slope, and it follows that $T^w$ is of finite type over $K$ if and only if $w$ is a scalar multiple of a lattice point.

When the schemes $T^w$ and $X^w$ are not of finite type, there are many technical difficulties in handling them directly. These technical difficulties can be overcome by extending scalars, since these schemes become finite type after a suitable base change, as follows.

Suppose the value group $G$ is a proper subgroup of $\mathbb{R}$, and $b$ is a real number that is not in $G$. Then there is a unique valuation $\tilde{\nu}$ on the function field $\tilde{K}(t)$ such that $\tilde{\nu}(t) = b$. This valuation extends to the algebraic closure $\overline{\tilde{K}}$ of $\tilde{K}(t)$. Iterating this procedure finitely many times, we can ensure that an arbitrary $w$ is rational over the value group of a suitable extension of $K$. In particular, for a suitable choice of extension $K'|K$, the scheme $\tilde{T}_w$ is of finite type over the valuation ring $\tilde{R}$.

Let $\tilde{K}|K$ be an arbitrary extension of valued fields, and let $\tilde{G}$ be the value group of $\tilde{K}$, with $\tilde{R}$ the valuation ring in $\tilde{K}$. For any closed subscheme $X$ of $T$ over $K$, the tropicalization of the base change $\tilde{X}$ is equal to the tropicalization of $X$ [Pay09a, Proposition 6.1], so the initial degeneration $\tilde{X}_w$ is nonempty if and only if $X_w$ is nonempty. Here we give a more precise geometric relationship between these initial degenerations. First we treat the associated schemes over the valuation rings. Let
\[
\varphi : \tilde{T}_w \to T_w
\]
be the natural map induced by the inclusion of tilted group rings, which is equivariant over the projection of tori induced by the inclusions $M_{G,w} \hookrightarrow M_{\tilde{G},w}$ and $R \hookrightarrow \tilde{R}$.
The scheme $\tilde{X}^w$ is the preimage of $X^w$ under $\varphi$.

**Proof.** It is clear that $\varphi$ maps $\tilde{X}^w$ into $X^w$. To show that $\tilde{X}^w$ is the full preimage of $X^w$, we must prove that any Laurent polynomial in the tilted group ring $\tilde{R}[M]^w$ that vanishes on $\tilde{X}$ is in the ideal generated by $I_X \cap R[M]^w$.

Let $f = \sum u \alpha(u)x^u$ be a nonzero Laurent polynomial over $\tilde{K}$ in $I_{\tilde{X}}$. Then $f$ can be written as

$$f = \alpha_1 f_1 + \cdots + \alpha_n f_n,$$

with $f_1, \ldots, f_n$ in $I_X$ and linearly independent over $K$, and $\alpha_i$ in $\tilde{K}$ all nonzero. Say $\alpha_i(u)$ is the coefficient of $x^u$ in $f_i$, so the coefficient of $x^u$ in $f$ is

$$\alpha(u) = \alpha_1 \alpha_1(u) + \cdots + \alpha_n \alpha_n(u).$$

Now, suppose $f$ is in $\tilde{R}[M]^w$. If each $\alpha_i f_i$ is in $\tilde{R}[M]^w$, then it is easy to see that $f$ is in the ideal generated by $I_X \cap R[M]^w$, by applying the case $n = 1$, below. The difficulty is that there may be some cancellation of leading terms in the above expression for $f$, by which we mean that the valuation of some coefficient $\alpha(u)$ may be strictly larger than $\min_i \{\tilde{v}(\alpha_1 \alpha_1(u))\}$. Roughly speaking, this means that the vector $(\alpha_1, \ldots, \alpha_n)$ is nearly orthogonal to $(\alpha_1(u), \ldots, \alpha_n(u))$.

When $n$ is greater than 1, we proceed by carefully eliminating one term in the summation, writing $f$ as a $\tilde{K}$-linear combination of $f_1, \ldots, f_{n-1}$ plus a single element of $\tilde{K}$ times a $K$-linear combination of $f_1, \ldots, f_n$. A suitable choice in the elimination procedure ensures that each of these two terms is in $\tilde{R}[M]^w$, and we deduce that they are in the ideal generated by $I_X \cap R[M]^w$, by induction on $n$. Roughly speaking, we choose $u_1, \ldots, u_{n-1}$ so that $(\alpha_1(u_i), \ldots, \alpha_n(u_i))$ are as close to orthogonal as possible to $(\alpha_1, \ldots, \alpha_n)$, for $1 \leq i \leq n - 1$. Then we replace $(\alpha_1, \ldots, \alpha_n)$ by the unique vector in $K^n$ that is orthogonal to $(\alpha_1(u_i), \ldots, \alpha_n(u_i))$ for $1 \leq i \leq n - 1$ and with $n$th coordinate 1. The corresponding $K$-linear combination of $f_1, \ldots, f_n$ is then multiplied by $\alpha_n$ and subtracted from $f$. The details are as follows.

Suppose $n = 1$. Let $m = \alpha_1(u)x^u$ be a monomial of lowest weight in $f_1$, and let $g = f_1/m$. Then $f$ can be expressed as

$$f = \alpha_1 mg,$$

with $g$ in $I_X \cap R[M]^w$, and $\alpha_1 m$ in $\tilde{R}[M]^w$, as required.

We proceed by induction on $n$. Given $u_1, \ldots, u_{n-1}$ in $M$, consider the matrix whose $(i, j)$th entry is $a_i(u_j)$, and let $\delta_i$ be the $i$th maximal minor

$$\delta_i = \begin{vmatrix} a_1(u_1) & \cdots & a_1(u_{n-1}) \\ \vdots & \ddots & \vdots \\ a_i(u_1) & \cdots & a_i(u_{n-1}) \\ \vdots & \ddots & \vdots \\ a_n(u_1) & \cdots & a_n(u_{n-1}) \end{vmatrix}$$
Since $f_1, \ldots, f_{n-1}$ are linearly independent over $K$, we may choose $u_1, \ldots, u_{n-1}$ so that $\delta_n$ is nonzero and  
\[ \tilde{\nu}(\alpha(u_1)) + \cdots + \tilde{\nu}(\alpha(u_{n-1})) - \nu(\delta_n) \]
is as large as possible. This choice is essential in the proof of the following claim. 
We claim that  
\[ h = \frac{\alpha_n}{\delta_n} \sum_{i=1}^{n} (-1)^{n-i} \delta_i f_i \]
is in $\tilde{R}[M]^w$. The claim implies that $h$ is in the ideal generated by $I_X \cap R[M]^w$, by the case $n = 1$, above, and also that the difference $f - h$ is in $\tilde{R}[M]^w$. The coefficient of $f_n$ in the above expression is equal to $\alpha_n$, by construction, so the difference $f - h$ can be written as a $\tilde{K}$-linear combination of $f_1, \ldots, f_{n-1}$. It follows by induction that $f - h$ is also in the ideal generated by $I_X \cap R[M]^w$, and this proves the theorem. 
It therefore remains to show that $h = \sum \beta(u)x^w$ is in $\tilde{R}[M]^w$, which means that the $w$-weight of each monomial $\beta(u)x^w$ is nonnegative. Fix one such monomial, write $u_n = u$ for its exponent, and let $A$ be the square $n \times n$ matrix whose $(i, j)$th entry is $a_i(u_j)$,  
\[ A = \begin{pmatrix} a_1(u_1) & \cdots & a_1(u_n) \\ \vdots & \ddots & \vdots \\ a_n(u_1) & \cdots & a_n(u_n) \end{pmatrix}. \]
Let $A_{ij}$ be the $(i, j)$th minor of $A$, the determinant of the submatrix obtained by deleting the $i$th row and $j$th column. So $\delta_i = A_{in}$. Expanding $\det A$ in the last column shows that  
\[ \beta(u_n) = \frac{\alpha_n}{A_{nn}} \det A. \]
Therefore, the valuation of $\beta(u_n)$ is  
\[ \tilde{\nu}(\beta(u_n)) = \nu(\det A) - \nu(A_{nn}) + \tilde{\nu}(\alpha_n). \]
Since $f$ is in $\tilde{R}[M]^w$ by hypothesis, it will be enough to show that $\tilde{\nu}(\beta(u_n))$ is at least as large as $\tilde{\nu}(\alpha(u_n))$. To compare $\beta(u_n)$ with $\alpha(u_n)$, we consider the matrix  
\[ A' = \begin{pmatrix} \alpha_1 a_1(u_1) & \cdots & \alpha_1 a_2(u_n) \\ \vdots & \ddots & \vdots \\ \alpha_{n-1} a_{n-1}(u_1) & \cdots & \alpha_{n-1} a_{n-1}(u_n) \\ \alpha(u_1) & \cdots & \alpha(u_n) \end{pmatrix}. \]
Recall that the coefficient $\alpha(u_j)$ in the bottom row is $\alpha_1 a_1(u_j) + \cdots + \alpha_n a_n(u_j)$, so the determinant of $A'$ is $\alpha_1 \cdots \alpha_n \det A$. Expanding $\det A'$ in the last row gives also  
\[ \det A' = \alpha_1 \cdots \alpha_{n-1} \left( \sum_{i=1}^{n} (-1)^{n-i} \alpha(u_i) A_{ni} \right), \]
and comparing these two expressions for $\det A'$ yields

$$\det A = \frac{1}{\alpha_n} \left( \sum_{i=1}^{n} (-1)^{n-i} \alpha(u_i) A_{ni} \right).$$

Therefore,

$$\nu(\det A) \geq \min_i \{ \nu(\alpha(u_i)) + \nu(A_{ni}) \} - \nu(\alpha_n).$$

Now $u_1, \ldots, u_{n-1}$ were chosen so that this minimum occurs at $i = n$. Substituting the resulting inequality for $\nu(\det A)$ into the expression for $\tilde{\nu}(\beta(u_n))$ above shows that $\tilde{\nu}(\beta(u_n))$ is greater than or equal to $\tilde{\nu}(\alpha(u_n))$. This proves the claim, and the theorem follows.

We now pass to the initial degenerations. Let

$$\phi: \tilde{T}_w \to T_w$$

be the natural projection of torus torsors induced by the inclusions of tilted group rings, modulo monomials of strictly positive $w$-weight.

**Theorem A.4.** The initial degeneration $\tilde{X}_w$ is the preimage of $X_w$ under $\phi$.

**Proof.** It is clear that $\phi$ maps $\tilde{X}_w$ into $X_w$. Any element $f_w$ of the ideal of $\tilde{X}_w$ is the residue of a Laurent polynomial $f$ in $I_{\tilde{X}} \cap \tilde{R}[M]^w$, which is then in the ideal generated by $I_X \cap \tilde{R}[M]^w$, by Theorem A.3. Taking residues shows that $f_w$ in the ideal generated by the pullback of $I_{X_w}$, and it follows that $\tilde{X}_w$ is the full preimage of $X_w$. \qed

**Remark A.5.** Since $\phi$ is smooth and has connected fibers, it follows that many geometric properties of initial degenerations are preserved under extensions of valued fields. For instance, the sum of the multiplicities of the irreducible components of $X_w$ is equal to that of $\tilde{X}_w$, which is helpful for defining tropical multiplicities. Most importantly for our purposes, a point $\tilde{x}$ is smooth in $\tilde{Y}_w$ if and only if $\phi(\tilde{x})$ is smooth in $Y_w$, $\tilde{X}_w$ meets $\tilde{X}'_w$ properly at $\tilde{x}$ if and only if $X_w$ meets $X'_w$ properly at $\phi(\tilde{x})$, and $\tilde{x}$ is in $(\tilde{X} \cap \tilde{X}')_w$ if and only if $\phi(\tilde{x})$ is in $(X \cap X')_w$.

**Appendix B. Topology of finite type morphisms**

Because the results may be of independent interest, we explain how Theorem 4.2.5 on the existence of closed points in fibers, and Theorem 4.1.3 on lifting points of intersection, can both be extended to an arbitrary base scheme. The proof of Proposition 4.2.2 does not use that the base scheme is the spectrum of a valuation ring of rank 1, and in fact yields the following result.

**Proposition B.1.** Let $X \to S$ be a flat morphism of finite type of irreducible schemes, and suppose that $D$ is a locally principal closed subscheme of $X$ that does not meet the generic fiber. Then, for every $s \in S$, every irreducible component of the fiber $D_s$ is an irreducible component of $X_s$. 
Remark B.2. Some hypothesis such as flatness is necessary for such results on locally principal subschemes over general base schemes, as shown by the following example. Suppose $X \to S$ is the blowup of the affine plane at the origin. Then the strict transform $D$ of a line through the origin is locally principal and does not meet the generic fiber, but its intersection with the exceptional fiber is a single point.

We can now prove the first stated result.

**Theorem B.3.** Let $X \to S$ be a morphism locally of finite type, and let $s$ be a specialization of $s'$ in $S$. Suppose $x'$ is a point in $X_{s'}$ specializing to a closed point $x$ in $X_s$. Then there is a closed point $x''$ in $X_{s'}$ which specializes to $x$, and such that $x'$ specializes to $x''$. Moreover, the set of such $x''$ is Zariski dense in the closure of $x'$ inside $X_{s'}$. More generally, if $x$ is not necessarily closed in $X_s$, and $k(x)$ denotes the residue field of $x$, we can choose $x''$ to satisfy the inequality

$$ (B.1) \quad \text{trdeg} k(x'')/k(s') \leq \text{trdeg} k(x)/k(s), $$

and again the choices of $x''$ are Zariski dense in the closure of $x'$ inside $X_{s'}$. Moreover, if $S$ is the spectrum of a valuation ring, we have equality in (B.1).

Note that the example of Remark B.2 shows that we cannot do better than the inequality (B.1) for a general base scheme.

**Proof.** First, in light of the generalized Proposition B.1, the argument of Theorem 4.2.5 goes through to prove the desired result in the case that $S$ is an arbitrary valuation ring, with $s'$ the generic point of $S$. The only subtlety is that in the general case, the components of $D$ not containing $x$ do not necessarily form a closed subset. Nonetheless, we can pass to an open neighborhood of $x$ such that every component of $D$ meeting the generic fiber (if there are any) must contain $x$, and this suffices for the argument. To remove the restriction that $s'$ be the generic point of $S$, we simply note that the closure of $s'$ is again the spectrum of a valuation ring.

We thus wish to reduce to the valuation ring case. Replacing $X$ by the closure of $x'$, we may assume $X$ is integral and $x'$ is its generic point. By [Gro61a Proposition 7.1.4(ii)], there is a valuation ring $A$ in $k(x')$ with a dominant morphism $\text{Spec } A \to X$

mapping the closed point to $x$. Let $R$ be the valuation ring in the residue field $k(s')$ given by intersecting with $A$ in $k(x')$, and let $X' = X \times_S \text{Spec } R$. Then the following diagram is commutative.

$$
\begin{array}{ccc}
X' & \longrightarrow & X \\
\downarrow & & \downarrow \\
\text{Spec } R & \longrightarrow & S
\end{array}
$$

Documenta Mathematica 18 (2013) 121–175
By construction the map from Spec $A$ to $X$ factors through $X'$. So, by the case we have already handled, there is a point $x''$ in the generic fiber of $X'$ over Spec $R$ specializing to the image $\tilde{x}$ in $X'$ of the closed point of Spec $A$ and satisfying the desired equality of residue field extensions; moreover, such points are Zariski dense in the generic fiber. Since $k(s')$ is identified with the fraction field of $R$, by construction, the generic fiber of $X'$ maps isomorphically to the generic fiber of $X$. Finally, observing that we have the inequality

$$\text{trdeg} \kappa(\tilde{x})/(R/m_R) \leq \text{trdeg} \kappa(x)/k(s),$$

we conclude the desired statement. □

Naive statements about global codimension and subadditivity do not extend from valuation rings of rank 1 to valuation rings of higher rank, as shown by Example 4.3.2. Nevertheless, hypotheses on codimension of intersection can still yield lifting results even when subadditivity of codimension fails, as demonstrated by the following theorem.

**Theorem B.4**. Let $Y \to S$ be a smooth morphism, and let $X$ and $X'$ be closed subschemes of $Y$, flat over $S$, such that the codimension in $Y'$ of every component of $X$ and every component of $X'$ is less than or equal to $j$ and $j'$, respectively. Suppose that, for some $s \in S$, the fibers $X_s$ and $X'_s$ meet in codimension $j + j'$ at a point $x$ in $Y_s$. Then for any $s' \in S$ specializing to $s$:

1. There is a point $x'$ in $X_s' \cap X'_s$ specializing to $x$.
2. If $x$ is closed in $Y_s$, then $x'$ may be chosen to be closed in $Y'_s$. More generally, we may choose $x'$ so that we have

$$\text{trdeg} \kappa(x')/k(s') \leq \text{trdeg} \kappa(x)/k(s).$$

**Proof.** In light of Theorem B.3, the second assertion follows immediately from the first. Observe that the flatness hypotheses mean that the hypotheses of the theorem are preserved under arbitrary base change. In particular, we reduce to the case that $S$ is the spectrum of a valuation ring, with $s'$ the generic point. We then prove the desired statement with a reduction to the diagonal and inductive application of Proposition B.1, using that $S$ is the spectrum of a valuation ring to preserve the flatness hypothesis. □

**Remark B.5.** In Example 4.3.2 the special fibers of the two subschemes coincide, and the generic fibers are disjoint. This does not contradict Theorem B.4 because the special fibers do not meet properly, and the failure of subadditivity is for simple numerical reasons. The intersection that does not lift has dimension one larger than expected, but is supported in a fiber of codimension $r$, which is greater than 1.

**Appendix C. An application to tropical elimination theory**

Let $X$ be an irreducible closed subscheme of $T$ and let $\varphi : T \to T'$ be a homomorphism of tori that induces a generically finite morphism from $X$ to the closure of its image, which we denote $X'$. Then, set theoretically, $\text{Trop}(X')$
is the image of $\text{Trop}(X)$ under the induced linear map $\phi : N_R \to N'_{R'}$. The fundamental problem of tropical elimination theory, solved by Sturmfels and Tevelev for the special case where the valuation is trivial, is to determine the multiplicities on the facets of $\text{Trop}(X')$. Here we use tropical lifting theorems to generalize [ST08, Theorem 1.1] to the case of a nontrivial valuation. See also [BPR11, Section 8] for an analytic proof of this result and applications to curves.

After subdividing, we may assume that $\phi$ maps each face of $\text{Trop}(X)$ onto a face of $\text{Trop}(X')$.

**Theorem C.1.** The multiplicity of a facet $\sigma'$ in $\text{Trop}(X')$ is

$$m(\sigma') = \frac{1}{\delta} \sum_{\phi(\sigma) = \sigma'} m(\sigma) \cdot [N'_{\sigma} : \phi(N_\sigma)],$$

where $\delta$ is the degree of $\phi$.

Theorem C.1 and Corollary [4.4.6] together imply that tropicalization of cycles commutes with push forward. See [Gub12, Theorem 13.17].

**Proof.** We prove the theorem by intersecting $X$ and $X'$ with suitable translates of subtori and then counting points using tropical intersection theory and lifting theorems. First, we choose the translated subtori to ensure that these intersections occur in a locus where $\alpha$ is well-behaved.

Since $\phi$ is generically finite, there is a dense open subset $U' \subset X'$ such that the induced map $\varphi^{-1}(U') \rightarrow U'$ is finite of degree $\delta$ [Har77, Exercise II.3.7]. Shrinking $U'$ further, if necessary, we may assume that $U'$ is smooth and $\varphi^{-1}(U')$ is flat over $U'$, so the preimage of a zero-dimensional subscheme of length $m$ in $U$ is a zero-dimensional subscheme of length $\delta \cdot m$.

Let $\Lambda'$ be a sublattice of $N'$ complementary to $N'_{\sigma'}$, so $N'$ splits as a direct sum

$$N' = N'_{\sigma'} \oplus \Lambda'.$$

We write $T'_{\Lambda'}$ for the subtorus of $T'$ whose lattice of one-parameter subgroups is $\Lambda'$. Let $\Lambda \subset N$ be the preimage of $\Lambda'$, with $T_{\Lambda}$ the associated subtorus of $T$. Let $\tilde{T}_{\Lambda}$ be the preimage of $T'_{\Lambda'}$, which is the product of $T_{\Lambda}$ with a zero-dimensional scheme of length $\ell = [N' : \phi(N)] / [\Lambda' : \phi(\Lambda)]$.

If the characteristic of $K$ is zero, or prime to $\ell$, then $\tilde{T}_{\Lambda}$ is a union of translates of $T_{\Lambda}$ by $\ell$ distinct torsion points.

We claim that, for any nonempty open subset $U \subset X$ there is an open dense set of $t \in T$ such that $t \tilde{T}_{\Lambda} \cap X$ is contained in $U$. To see this, consider the incidence subscheme $W$ in $T \times X$ parametrizing pairs $(t, x)$ such that $x$ is in $t \tilde{T}_{\Lambda}$. Then the first projection is dominant and generically finite, while the second projection is flat and maps $W$ surjectively onto $X$. Therefore, the preimage of $X \setminus U$ has positive codimension in $W$ and hence projects into a set of positive codimension in $T$. Therefore the complement of the closure of $p_1(p_2^{-1}(X \setminus U))$...
of these intersections that live in $\text{Trop}(X)$.

We fix
d and choose $v \in N_\mathbb{G}$ such that $v' = \phi(v)$ is in the relative interior of $\sigma'$. Since $\text{Trop}^{-1}(v)$ is Zariski dense in $T$, we can choose $t \in \text{Trop}^{-1}(v)$ in the open dense subset of $T$ described above, such that $t \tilde{T}_\Lambda \cap X$ is contained in $U$. Note that, since $v'$ is in the relative interior of the maximal face $\sigma'$ of $\text{Trop}(X')$, it has finitely many preimages $v_1, \ldots, v_r$ in $\text{Trop}(X)$, one in each maximal face $\sigma_i$ mapping onto $\sigma'$. Let $\sigma_i$ be the maximal face of $\text{Trop}(X)$ containing $v_i$.

Let $t' = \varphi(t)$. We now consider $t'T'_{\Lambda'} \cap X'$ and $t \tilde{T}_\Lambda \cap X$, and especially the parts of these intersections that live in $\text{Trop}^{-1}(v')$ and $\text{Trop}^{-1}(v_i)$, for $1 \leq i \leq r$, respectively. By construction, $\text{Trop}(t'T'_{\Lambda'})$ is the affine linear space $A_{\mathbb{G}} + v'$ with multiplicity 1, and meets $\text{Trop}(X')$ transversally at $v'$. The translation of $t'T'_{\Lambda'}$, by a sufficiently small vector in $N_{\mathbb{G}}$, also meets $\sigma'$ transversally at a single point, so the fan displacement rule gives the local tropical intersection multiplicity as

$$i(v', \text{Trop}(X') \cdot \text{Trop}(t'T'_{\Lambda'})) = m(\sigma') \cdot [N' : N_{\sigma'} + \Lambda'].$$

By the choice of $t$, the intersection of $t'T'_{\Lambda'}$ with $X'$ is contained in the smooth locus of $X'$. In particular, both are Cohen-Macaulay along their intersection in $\text{Trop}^{-1}(v')$. Therefore, Corollary 5.1.3 says that the intersection of $X'$ with $t'T'_{\Lambda'}$, in $\text{Trop}^{-1}(v')$ is a zero-dimensional scheme $Z'$ of length $i(v', \text{Trop}(X') \cdot \text{Trop}(t'T'_{\Lambda'}))$. Similarly, $\text{Trop}(t \tilde{T}_\Lambda)$ is the affine linear space $A_{\mathbb{G}} + v$ with multiplicity $\ell$, and meets $\text{Trop}(X)$ transversally at $v_i$ with local tropical intersection multiplicity

$$i(v, \text{Trop}(X) \cdot \text{Trop}(t \tilde{T}_\Lambda)) = \ell \cdot m(\sigma_i) \cdot [N : N_{\sigma_i} + \Lambda].$$

Both $t \tilde{T}_\Lambda$ and $X$ are smooth and hence Cohen-Macaulay along their intersection, so the intersection of $t \tilde{T}_\Lambda$ with $X$ in $\text{Trop}^{-1}(v_i)$ is a zero-dimensional scheme $Z_i$ of length $i(v, \text{Trop}(X) \cdot \text{Trop}(t \tilde{T}_\Lambda))$.

By the choice of $t$, the map $\varphi$ is finite of degree $\delta$ in a neighborhood of $Z'$. Furthermore, the preimage $\varphi^{-1}(Z')$ is exactly $Z_1 \cup \cdots \cup Z_r$. Therefore,

$$\text{length}(Z') = \frac{1}{\delta} \cdot \text{length}(Z_1) + \cdots + \text{length}(Z_r)).$$

Substituting the above tropical intersection multiplicities for these lengths gives the identity

$$m(\sigma') \cdot [N' : N_{\sigma'} + \Lambda'] = \frac{\ell}{\delta} \cdot \sum_{i=1}^{r} m(\sigma_i) \cdot [N : N_{\sigma_i} + \Lambda].$$

Now $\sigma_1, \ldots, \sigma_r$ are exactly the faces of $\text{Trop}(X)$ that map onto $\sigma$, and $\ell = [N' : \phi(N)]/[N : \phi(\Lambda)]$. By rearranging terms, one then sees that, to prove the theorem, it suffices to show

$$[N' : \phi(N)] \cdot [N : N_{\sigma} + \Lambda] = [N'_{\sigma} : \phi(N_{\sigma})] \cdot [\Lambda' : \phi(\Lambda)].$$
for $1 \leq i \leq r$. Both sides are equal to $[N' : \phi(N_\sigma + \Lambda)]$, and the theorem follows. □

Cycle Classes for $p$-adic Étale Tate Twists and the Image of $p$-adic Regulators

Kanetomo Sato$^1$

Received: December 23, 2011
Revised: February 8, 2013
Communicated by Stephen Lichtenbaum

Abstract. In this paper, we construct Chern class maps and cycle class maps with values in $p$-adic étale Tate twists $[Sa2]$. We also relate the $p$-adic étale Tate twists with the finite part of Bloch-Kato. As an application, we prove that the integral part of $p$-adic regulator maps has values in the finite part of Galois cohomology under certain assumptions.

2000 Mathematics Subject Classification: Primary 19F27, 14F30; Secondary 14C25

1 Introduction

Let $p$ be a rational prime number. Let $A$ be a Dedekind ring whose fraction field has characteristic zero and which has a residue field of characteristic $p$. Let $X$ be a regular scheme of pure-dimension which is flat of finite type over $S := \text{Spec}(A)$ and which is a smooth or semistable family around its fibers over $S$ of characteristic $p$. Extending the idea of Schneider [Sc], the author defined in $[Sa2]$ the objects $\Xi_n(r)_X (r, n \geq 0)$ of the derived category of étale $\mathbb{Z}/p^n$-sheaves on $X$ playing the role of the $r$-th Tate twist with $\mathbb{Z}/p^n$-coefficients, which are endowed with a natural product structure with respect to $r$ and both contravariantly and covariantly functorial (i.e., there exist natural pull-back and trace morphisms) for arbitrary separated morphisms of finite type of such schemes. Those pull-back and trace morphisms satisfy the projection formula.

The first aim of this paper is to construct the following Chern class map and cycle class map for $m, r \geq 0$:

$$
\begin{array}{ccc}
K_m(X) & \xrightarrow{\text{(missing)}} & C_{r,m} \quad \text{(Chern class)} \\
\text{CH}^r(X, m) & \xrightarrow{\sigma^r_{X,m}} & H^{2r-m}_{\text{ét}}(X, \Xi_n(r)_X),
\end{array}
$$

$^1$supported by JSPS Core-to-Core Program 18005 and Grant-in-Aid for Scientific Research B-23340003
where $K_m(X)$ denotes the algebraic $K$-group $[Q]$ and $\text{CH}^r(X, m)$ denotes the higher Chow group $[B2]$. The Chern classes with values in higher Chow groups have not been defined in this arithmetic situation for the lack of a product structure on them, which we do not deal with in this paper. We will prepare the following results to construct the above maps:

(a) The Dold-Thom isomorphism, i.e., the projective bundle formula for $p$-adic étale Tate twists. See Theorem 4.1 below for details. We note here that the $p$-adic étale Tate twists do not satisfy homotopy invariance.

(b) For a regular closed immersion $i : X_\ast \hookrightarrow X'_\ast$ of codimension $c$ of simplicial schemes for which the $p$-adic étale Tate twists are defined, we construct a Gysin morphism $\text{gys}_i : \mathcal{I}(r)_{X_\ast} \longrightarrow \text{Ri}^!\mathcal{I}(r+c)_{X'_\ast} \otimes [2c]$ in $D((X_\ast)_{\text{et}}, \mathbb{Z}/p^n)$ satisfying transitivity and projection formula. See Proposition 5.4 below for details.

(c) We introduce a version of $p$-adic étale Tate twists with log poles along horizontal normal crossing divisors (see §3 below), and prove a $p$-adic analogue of the usual homotopy invariance (see Corollary 4.3 below) and a semi-purity property (see Theorem 6.5 below) for this new coefficient.

The existence of $C_{r,m}$ will be verified by (a) and the general framework due to Gillet [Gi1]. The additivity of $C_{r,m}$ for $m \geq 1$ will follow from (b) (cf. §5). On the other hand, we will need the results in (c) to construct $\text{cl}^m_{X}$ (cf. §7). This ‘higher’ cycle class map will be a fundamental object to study in ‘higher’ higher classfield theory [Sai]. We will mention a local behavior of $\text{cl}^m_X$ in Remark 7.2 below.

The second aim of this paper is to relate the $p$-adic étale Tate twists with the finite part of Galois cohomology [BK2], using the Fontaine-Jannsen conjecture proved by Hyodo, Kato and Tsuji ([HK], [K4], [Ts1], cf. [Ni2]). We assume here that $A$ is a $p$-adic integer ring and that $X$ is projective over $A$ with strict semistable reduction. Let $K$ be the fraction field of $A$ and put $X_K := X \otimes_A K = X[p^{-1}]$. We define

$$H^i(X, \mathcal{I}_{Q_p}(r)_X) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^i_{\text{et}}(X, \mathcal{I}_n(r)_X),$$

$$H^i(X_K, \mathcal{I}_{Q_p}(r)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^i_{\text{et}}(X_K, \mu_{p^n} \otimes r),$$

where $\mu_{p^n}$ denotes the étale sheaf of $p^n$-th roots of unity on $X_K$, i.e., the usual Tate twist on $X_K$. We have a natural restriction map $H^i(X, \mathcal{I}_{Q_p}(r)_X) \rightarrow H^i(X_K, \mathcal{I}_{Q_p}(r))$ and a canonical descending filtration $F^\ast$ on $H^i(X_K, \mathcal{I}_{Q_p}(r))$ resulting from the Hochschild-Serre spectral sequence for the covering $X_K \leftarrow X_K \otimes K \rightarrow X_K$ (cf. (9.0.1)). We define a (not necessarily exhaustive) filtration $F^\ast$ on $H^i(X, \mathcal{I}_{Q_p}(r)_X)$ as the inverse image of $F^\ast$ on $H^i(X_K, \mathcal{I}_{Q_p}(r))$, which induces obvious inclusions for $m \geq 0$

$$\text{gr}^m F^i H^i(X, \mathcal{I}_{Q_p}(r)_X) \subseteq \text{gr}^m F^i H^i(X_K, \mathcal{I}_{Q_p}(r)) \approx H^m(K, H^{i-m}(X_K, \mathcal{I}_{Q_p}(r))).$$
Here $H^i(K, -)$ denotes the continuous Galois cohomology of the absolute Galois group $G_K = \text{Gal}(\overline{K}/K)$ defined by Tate [Ta]. We will prove that

$$\text{gr}_p^1 H^i(X, \mathcal{T}_{\mathbb{Q}_p}(r)_{\chi}) \subset H^i_f(K, H^{i-1}(X_{\mathbb{P}^1}, \mathbb{Q}_p(r))) \quad (f = \text{finite part})$$

assuming that $p$ is sufficiently large and that the monodromy-weight conjecture [Mo] holds for the log crystalline cohomology of the reduction of $X$ in degree $i - 1$ (see Theorem 9.1 below). This result is an extension of the $p$-adic point conjecture ([Sc], [LS], [Ne1]) to the semistable reduction case and gives an ‘unramified’ version of results of Langer [La] and Nekovář [Ne2] relating the log syntomic cohomology of $X$ with the geometric part $H^i_f(K, H^{i-1}(X_{\mathbb{P}^1}, \mathbb{Q}_p(r)))$.

There is an application of the above results as follows. Let $K$ be a number field and let $V$ be a proper smooth geometrically integral variety over $K$. Put $\overline{V} := V \otimes_K \overline{K}$. Let $i$ and $r$ be non-negative integers with $2r \geq i + 1$, and let $p$ be a prime number. The étale Chern characters (cf. [So]) induce $p$-adic regulator maps

$$\text{reg}^{2r-i-1,r}_p : K_{2r-i-1}(V)_\text{o} \longrightarrow H^i_f(K, H^i(\overline{V}, \mathbb{Q}_p(r))) \quad (2r > i + 1),$$

$$\text{reg}^{0,r}_p : K_0(V)_{\text{hom}} \longrightarrow H^1_f(K, H^{2r-1}(\overline{V}, \mathbb{Q}_p(r))) \quad (2r = i + 1).$$

Here $K_0(V)_{\text{hom}}$ denotes the homologically trivial part of $K_0(V)$, and $K_{m}(V)_o$ denotes the integral part of $K_{m}(V)$ in the sense of Scholl (see §10 below). Motivated by the study of special values of $L$-functions, Bloch and Kato [BK2] conjecture that the image of $\text{reg}^{2r-i-1,r}_p$ is contained in the finite part $H^i_f(K, H^i(\overline{V}, \mathbb{Q}_p(r)))$ and spans it over $\mathbb{Q}_p$. In the direction of this conjecture, we will prove the following result, which extends a result of Nekovář [Ne2] Theorem 3.1 on $\text{reg}^{0,r}_p$ to the case $2r > i + 1$ and extends a result of Niziol [Ni1] on the potentially good reduction case to the general case:

**Theorem 1.1** (§10) **Assume $r \leq p - 2$ and the monodromy-weight conjecture for the log crystalline cohomology of degree $i$ of projective strict semistable varieties over $\mathbb{F}_p$. Then we have**

$$\text{Im}(\text{reg}^{2r-i-1,r}_p) \subset H^i_f(K, H^i(\overline{V}, \mathbb{Q}_p(r))).$$

Here a projective strict semistable variety over $\mathbb{F}_p$ means the reduction of a regular scheme which is projective flat over a $p$-adic integer ring with strict semistable reduction.

We use the alteration theorem of de Jong [dJ] to prove Theorem 1.1, and the projective strict semistable varieties concerned in the assumption mean those obtained from alterations of scalar extensions of $V$ to the completion of $K$ at places dividing $p$.

This paper is organized as follows. In §2, we introduce cohomological and logarithmic Hodge-Witt sheaves with horizontal log poles on normal crossing varieties over a field of characteristic $p > 0$. In §3, we define $p$-adic étale Tate twists with horizontal log poles, and construct a localization sequence using this object (Theorem 3.12). In §4 and §5, we prove the Dold-Thom isomorphisms and define the Chern
class maps for $p$-adic étale Tate twists. The sections 6 and 7 will be devoted to the construction of cycle class maps for $p$-adic étale Tate twists. In §8 we will introduce Hodge-Witt cohomology and homology of normal crossing varieties and prove that the monodromy-weight conjecture implies a certain invariant cycle theorem. In §9, we establish the comparison between $p$-adic étale Tate twists and the finite part of Bloch-Kato. We will prove Theorem 1.1 in §10. In the appendix, we will formulate a continuous crystalline cohomology and a continuous syntomic cohomology to prove several technical compatibility results which will have been used in §9.

The author expresses his gratitude to Professors Shuji Saito and Takeshi Tsuji, and Masanori Asakura for valuable comments and discussions on the subjects of this paper.

Notation

For an abelian group $M$ and a positive integer $n$, $nM$ and $M/n$ denote the kernel and the cokernel of the map $M \to M$, respectively. For a field $k$, $\overline{k}$ denotes a fixed separable closure, and $G_k$ denotes the absolute Galois group $\text{Gal}(\overline{k}/k)$. For a topological $G_k$-module $M$, $H^*(k, M)$ denote the continuous Galois cohomology groups $H^*_{\text{cont}}(G_k, M)$ in the sense of Tate [Ta]. If $M$ is discrete, then $H^*(k, M)$ agree with the étale cohomology groups of $\text{Spec}(k)$ with coefficients in the étale sheaf associated with $M$.

Unless indicated otherwise, all cohomology groups of schemes are taken over the étale topology. For a scheme $X$, an abelian sheaf $\mathcal{F}$ on $X_{\text{ét}}$ (or more generally an object in the derived category of abelian sheaves on $X_{\text{ét}}$) and a point $x \in X$, we often write $H^*_e(X, \mathcal{F})$ for $H^*_e(\text{Spec}(\mathcal{O}_{X,x}), \mathcal{F})$. For a prime number $p$ which is invertible on $X$, we write $\mu_p$ for the étale sheaf of the $p$-th roots of unity on $X$. For a prime number $p$ which is invertible on $X$ and integers $m, r \geq 0$, we define

$$H^m(X, \mathbb{Z}_p(r)) := \lim_{\substack{\to \atop n \geq 1}} H^i(X, \mu_p^\otimes r^n),$$
$$H^m(X, \mathbb{Q}_p(r)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} H^m(X, \mathbb{Z}_p(r)).$$

For an equi-dimensional scheme $X$ and a non-negative integer $q$, we write $X^q$ for the set of all points on $X$ of codimension $q$.

For a scheme (or a simplicial scheme) $X$ and an integer $n \geq 2$, $\text{Shv}(X_{\text{ét}}, \mathbb{Z}/n)$ denotes the category of étale $\mathbb{Z}/n$-sheaves on $X_{\text{ét}}$, and $D(X_{\text{ét}}, \mathbb{Z}/n)$ denotes the derived category of complexes of objects of $\text{Shv}(X_{\text{ét}}, \mathbb{Z}/n)$.

2 Logarithmic Hodge-Witt sheaves

We first fix the following terminology.

**Definition 2.1**

1. A normal crossing variety over a field $k$ is a pure-dimensional scheme which is separated of finite type over $k$ and everywhere étale locally
isomorphic to
\[ \text{Spec}(k[t_0, \ldots, t_N]/(t_0 \cdots t_a)) \quad \text{for some} \quad 0 \leq a \leq N := \dim(Y). \]

(2) We say that a normal crossing variety \( Y \) is simple if all irreducible components of \( Y \) are smooth over \( k \).

(3) An admissible divisor on a normal crossing variety \( Y \) is a reduced effective Cartier divisor \( D \) such that the immersion \( D \hookrightarrow Y \) is everywhere étale locally isomorphic to
\[ \text{Spec}(k[t_0, \ldots, t_N]/(t_0 \cdots t_a, t_a+1 \cdots t_{a+b})) \hookrightarrow \text{Spec}(k[t_0, \ldots, t_N]/(t_0 \cdots t_a)) \]
for some \( a, b \geq 0 \) with \( a + b \leq N = \dim(Y) \).

Let \( p \) be a prime number, and let \( k \) be a field of characteristic \( p \). Let \( Y \) be a normal crossing variety over \( k \), and let \( D \) be an admissible divisor on \( Y \). Put \( V := Y - D \) and let \( f \) and \( g \) be as follows:
\[ D \twoheadrightarrow f \rightarrow \rightarrow V \quad \quad \quad \quad V \twoheadleftarrow g \leftarrow \leftarrow Y = Y - D. \]

For \( r \in \mathbb{Z} \), we define étale sheaves \( \nu^r_{(Y,D),n} \) and \( \lambda^r_{(Y,D),n} \) on \( Y \) as follows:
\[
\lambda^r_{(Y,D),n} := \ker \left( \partial : \bigoplus_{x \in V} i_x \ast W^r_x \Omega^q_{x, \log} \rightarrow \bigoplus_{x \in V} i_x \ast W^r_{x-1} \Omega^q_{x, \log} \right).
\]
Here for \( x \in V \), \( i_x \) denotes the composite map \( x \hookrightarrow V \hookrightarrow Y \), and \( W^q_x \Omega^q_{x, \log} \) denotes the étale subsheaf of the logarithmic part of the Hodge-Witt sheaf \( W^q_x \Omega^q_x \) (cf. [B1], [I1]), which means the zero sheaf for \( q < 0 \). The map \( \partial \) is the sum of boundary maps due to Kato [K1]. By definition, we have
\[
\lambda^r_{(Y,D),n} = \nu^r_{(Y,D),n} = 0 \quad \text{for} \quad r < 0.
\]
When \( D = \emptyset \), we put
\[
\nu^r_{Y,n} := \nu^r_{(Y,\emptyset),n} \quad \text{and} \quad \lambda^r_{Y,n} := \lambda^r_{(Y,\emptyset),n},
\]
which are considered in [Sa1]. Although we assumed the perfectness of \( k \) in [Sa1], the results in loc. cit. \( \S \S \) 2.1–2.4 and \( \S \S \) 3.1–3.2 are extended to the case that \( k \) is not necessarily perfect by results of Shiho [Sh] Theorems 3.2, 4.1 and the compatibility mentioned in [AS] Remark 7.3 (1). We have \( \nu^r_{(Y,D),n} = g_* \nu^r_{Y,n} \) by the left exactness of \( g_* \), and \( \nu^{r-1}_{D,n} \cong R^1 f_* \nu^r_{Y,n} \) by the purity of \( \nu^r_{Y,n} \) ([Sa1] Theorem 2.4.2). Hence there is a short exact sequence
\[
0 \twoheadrightarrow \nu^r_{Y,n} \twoheadrightarrow \nu^r_{(Y,D),n} \twoheadrightarrow f_* \nu^{r-1}_{D,n} \twoheadrightarrow 0. \quad (2.1.1)
\]
By this fact, we have

\[ \lambda_r^r(Y,D) = \nu^r(Y,D) = g_* W_n \Omega^r_{Y,\log} \]

if \( Y \) is smooth (loc. cit. (2.4.9)), which we denote by \( W_n \Omega^r_{Y,\log} \). The following proposition will be useful later, where \( Y \) is not necessarily smooth:

**Proposition 2.2** Assume that \( Y \) is simple, and let \( Y_1, Y_2, \ldots, Y_q \) be the distinct irreducible components of \( Y \). Then there is an exact sequence on \( Y_\mathfrak{et} \)

\[ 0 \longrightarrow \lambda^r_{(Y,D),n} \longrightarrow \bigoplus_{|I|=1} W_n \Omega^r_{(Y_1,D_1),\log} \longrightarrow \bigoplus_{|I|=2} W_n \Omega^r_{(Y_1,D_1),\log} \longrightarrow \cdots \longrightarrow \bigoplus_{|I|=q} W_n \Omega^r_{(Y_1,D_1),\log} \longrightarrow 0, \]

where the notation \(|I| = t\) means that \( I \) runs through all subsets of \( \{1, 2, \ldots, q\} \) consisting of \( t \) elements, and for such \( I = \{i_1, i_2, \ldots, i_t\} \) (\( i_j \)'s are pair-wise distinct), we put

\[ Y_I := Y_{i_1} \cap Y_{i_2} \cap \cdots \cap Y_{i_t} \quad \text{and} \quad D_I := D \times_Y Y_I. \]

The arrow \( r^0 \) denotes the natural restriction map. For \( (I, I') \) with \( I = \{i_1, i_2, \ldots, i_t\} \) (\( i_1 < i_2 < \cdots < i_t \)) and \( |I'| = t + 1 \), the \( (I, I') \)-factor of \( r^t \) is defined as

\[ \left\{ \begin{array}{ll}
0 & \text{(if } I \not\subset I') \\
(-1)^{t-n} \cdot (\beta_{I'I})^t & \text{(if } I' = I \cup \{i_{t+1}\} \text{ and } i_1 < \cdots < i_t < i_{t+1} < \cdots < i_{t+n}).
\end{array} \right. \]

where \( \beta_{I'I} \) denotes the closed immersion \( Y_{I'} \hookrightarrow Y_I \).

We need the following lemma to prove this proposition:

**Lemma 2.3** Assume that \( (Y, D, V) \) fits into cartesian squares of schemes

\[ \begin{array}{ccc}
D & \xrightarrow{f} & Y \\
\downarrow \circlearrowleft & & \downarrow \circlearrowleft \\
\mathcal{D} & \xrightarrow{h} & \mathcal{Y}
\end{array} \]

\[ \begin{array}{ccc}
\mathcal{D} & \xrightarrow{\psi} & \mathcal{V} \\
\downarrow \circlearrowleft & & \downarrow \circlearrowleft \\
\mathcal{D} & \xrightarrow{h} & \mathcal{Y}
\end{array} \]

such that \( \mathcal{Y} \) is regular, such that the vertical arrows are closed immersions and such that \( Y, \mathcal{D} \) and \( Y \cup \mathcal{D} \) are simple normal crossing divisors on \( \mathcal{Y} \), where we put \( \mathcal{Y}' := \mathcal{Y} \setminus \mathcal{D} \). Then the pull-back map \( \psi^* h_* \mathcal{O}_{\mathcal{Y}}^r \rightarrow g_* \mathcal{O}_{\mathcal{V}}^r \) on \( Y_\mathfrak{et} \) is surjective.

**Proof of Lemma 2.3.** We use the same notation as in Proposition 2.2. For a Cartier divisor \( E \) on a scheme \( Z \), let \( c_2^r(E) \in H^1_{\mathcal{E}l}(Z, \mathcal{O}_Z^r) \) be the localized first Chern class of the invertible sheaf \( \mathcal{O}_Z(E) \). Since \( \mathcal{Y} \) is regular, \( h_* \mathcal{O}_{\mathcal{Y}}^r \) is generated by \( \mathcal{O}_{\mathcal{Y}}^r \) and local uniformizers of the irreducible components \( \{ \mathcal{D}_j \}_{j \in J} \) of \( \mathcal{D} \). Put

\[ D_j := Y \times_{\mathcal{Y}} \mathcal{D}_j \quad (j \in J), \]

\[ \text{Documenta Mathematica 18 (2013) 177–247} \]
which is an admissible divisor on $Y$. Since $(g_*\mathcal{O}_Y^x)/\mathcal{O}_Y^x \simeq R^1f'_!\mathcal{O}_Y^x$, it is enough to show that the Gysin map
\[ \varphi : \bigoplus_{j \in J} \mathbb{Z}_{D_j} \rightarrow R^1f'_!\mathcal{O}_Y^x \]
sending $1 \in \mathbb{Z}_{D_j}$ to $c_{Y_1}(D_j)$ is bijective on $D_{\text{et}}$. By [Sa1] Lemma 3.2.2, there is an exact sequence on $Y_{\text{et}}$
\[ 0 \rightarrow \mathcal{O}_Y^x \stackrel{\varphi^0}{\rightarrow} \bigoplus_{|I|=1} \mathcal{O}_{Y_I}^{\times} \stackrel{\varphi^1}{\rightarrow} \bigoplus_{|I|=2} \mathcal{O}_{Y_I}^{\times} \cdots \stackrel{\varphi^{q-1}}{\rightarrow} \bigoplus_{|I|=q} \mathcal{O}_{Y_I}^{\times} \rightarrow 0, \quad (2.3.1) \]
where $\varphi^i$'s are defined in the same way as $\varphi^i$'s in Proposition 2.2, and $q$ denotes the number of the distinct irreducible components of $Y$. Since $f'_!\mathcal{O}_Y^x = 0$ for any non-empty subset $I \subset \{1, 2, \ldots, q\}$, the exactness of (2.3.1) implies that of the lower row of the following commutative diagram with exact rows:

\[
\begin{array}{cccccccc}
0 & \rightarrow & \bigoplus_{j \in J} \mathbb{Z}_{D_j} & \stackrel{\varphi^0}{\rightarrow} & \bigoplus_{|I|=1} \mathbb{Z}_{D_I \cap Y_I} & \stackrel{\varphi^1}{\rightarrow} & \bigoplus_{|I|=2} \mathbb{Z}_{D_I \cap Y_I} & \rightarrow & R^1f'_!\mathcal{O}_Y^x \\
& & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \bigoplus_{j \in J} \mathbb{Z}_{D_j} & \stackrel{\varphi^0}{\rightarrow} & \bigoplus_{|I|=1} \mathbb{Z}_{D_I \cap Y_I} & \stackrel{\varphi^1}{\rightarrow} & \bigoplus_{|I|=2} \mathbb{Z}_{D_I \cap Y_I} & \rightarrow & R^1f'_!\mathcal{O}_Y^x \\
\end{array}
\]

where $D_j \cap Y_I$ is regular for each $j \in J$ and $I \subset \{1, 2, \ldots, q\}$ by the assumption that $Y' \cup \mathcal{D}$ has simple normal crossings on $X$. The middle and the right vertical arrows are defined in the same way as for $\varphi$, and bijective by the standard purity for $\mathcal{O}^x$ ([Gr1] III §6). Hence $\varphi$ is bijective as well.

**Proof of Proposition 2.2.** Since the problem is étale local on $Y$, we may assume that $(Y, D, V)$ fits into a diagram as in Lemma 2.3. Then there is an exact sequence
\[ W_n \Omega^r_{(Y, D), \log} \stackrel{\varphi^0}{\rightarrow} \bigoplus_{|I|=1} W_n \Omega^r_{(Y_I, D_I), \log} \stackrel{\varphi^1}{\rightarrow} \cdots \stackrel{\varphi^{q-1}}{\rightarrow} \bigoplus_{|I|=q} W_n \Omega^r_{(Y_I, D_I), \log} \rightarrow 0 \]
on $\mathfrak{m}$ by Lemma 2.3 and induction on the number of components of $Y$ which is similar as for [Sa1] Lemma 3.2.2. The assertion follows from this exact sequence. \[ \square \]

3 \hspace{1em} \textit{p-adic étale Tate twists with log poles}

In §§3–7, we are mainly concerned with the following setting.

**Setting 3.1** Let $A$ be a Dedekind domain whose fraction field has characteristic 0 and which has a maximal ideal of positive characteristic. Put
\[ S := \text{Spec}(A). \]
Let $p$ be a prime number which is not invertible in $A$. Let $X$ be a regular scheme which is flat of finite type over $A$ and whose fibers over the closed points of $S$ of characteristic $p$ are empty or reduced normal crossing divisors on $X$. We write $Y \subset X$ for the union of those fibers, which may be empty.

Let $D \subset X$ be a normal crossing divisor such that $D \cup Y$ has normal crossings on $X$ ($D$ may be empty). Put $U := X - (Y \cup D)$ and $V := Y - (Y \cap D)$, and consider a diagram of immersions

$$
\begin{array}{ccc}
V & \subset & X - D \\
\subset & \quad & \quad \\
\cap & \quad & \quad \\
Y & \subset & X
\end{array}
$$

Let $n$ and $r$ be positive integers. We first state the Bloch-Kato-Hyodo theorem on the structure of the sheaf $M_n^r := i^*R^qj_*\mu_p^\otimes r$, which will be useful in this paper. We define the étale sheaf $\mathcal{M}_r^M$ on $Y$ as

$$
\mathcal{M}_r^M := (i^*j_*\mathcal{O}_U^\times)^\otimes n / J,
$$

where $J$ denotes the subsheaf of $(i^*j_*\mathcal{O}_U^\times)^\otimes n$ generated by local sections of the form $a_1 \otimes a_2 \otimes \cdots \otimes a_r$ with $a_s + a_t = 0$ or $1$ for some $1 \leq s < t \leq n$. There is a homomorphism of étale sheaves ([BK1] 1.2)

$$
\mathcal{M}_r^M \longrightarrow M_n^r,
$$

(3.1.1)

which is a geometric version of Tate’s Galois symbol map. For local sections $a_1, a_2, \ldots, a_r \in i^*j_*\mathcal{O}_U^\times$, we denote the class of $a_1 \otimes a_2 \otimes \cdots \otimes a_r$ in $\mathcal{M}_r^M$ by $\{a_1, a_2, \ldots, a_r\}$, and denote the image of $\{a_1, a_2, \ldots, a_r\}$ in $\mathcal{M}_r^M$ under (3.1.1) again by $\{a_1, a_2, \ldots, a_r\}$. We define filtrations $\mathcal{H}^*$ and $\mathcal{Y}^*$ on $M_n^r$ as follows.

**Definition 3.2** Put $p := \ker(\mathcal{O}_X \to i_*\mathcal{O}_Y)$ and $1 + p^q := \ker(\mathcal{O}_X^\times \to (\mathcal{O}_X/p^q)^\times)$ for $q \geq 1$.

1. We define $\mathcal{H}^0\mathcal{M}_n^r$ as the full sheaf $\mathcal{M}_n^r$. For $q \geq 1$, we define $\mathcal{H}^q\mathcal{M}_n^r \subset \mathcal{M}_n^r$ as the image of $i^*(1 + p^q) \otimes (i^*j_*\mathcal{O}_U^\times)^{\otimes r - 1}$.

2. For $q \geq 0$, we define $\mathcal{H}^qM_n^r$ as the image of $\mathcal{M}_n^r$ under the map (3.1.1).

3. When $A$ is local and its residue field $k$ has characteristic $p$, we fix a prime element $\pi \in A$ and define $\mathcal{Y}^rM_n^r \subset M_n^r$ as the part generated by $\mathcal{H}^{r+1}M_n^r$ and the image of $\mathcal{H}^rM_{n-1}^r \otimes (\pi)$ under (3.1.1).

Let $L_{X,s}$ be the log structure on $X$ associated with the normal crossing divisor $Y \cup D$ ([K3]), and let $L_{Y,s}$ be its inverse image log structure onto $Y_s$ (loc. cit. (1.4)). The following theorem is a variant of theorems of Bloch-Kato-Hyodo ([BK1] Theorem 1.4, [Hy1] Theorem 1.6), and the case $D = \emptyset$ corresponds to their theorems.

**Theorem 3.3** (1) The symbol map (3.1.1) is surjective, i.e., $\mathcal{H}^0M_n^r = M_n^r$.  

**Documenta Mathematica 18 (2013) 177–247**
(2) Assume that $A$ is local and that its residue field $k$ has characteristic $p$. Then there are isomorphisms
\[
M_n^r / \mathcal{Y}_n^r \overset{\sim}{\longrightarrow} W_n \omega_{Y_n, \log}^r,
\]
\[
\mathcal{Y}_n^r / \mathcal{Y}_n^{r+1} \overset{\sim}{\longrightarrow} W_n \omega_{Y_n, \log}^{r-1},
\]
where $W_n \omega_{Y_n, \log}^m$ denotes the image of the logarithmic differential map
\[
d \log : (L_{Y_n}^p)^{m} \longrightarrow \bigoplus_{y \in Y_n} i_y W_n \Omega_{y / \log}^m,
\]
and for a point $y \in Y$, $i_y$ denotes the natural map $y \mapsto Y$.

(3) Under the same assumption as in (2), let $e$ be the absolute ramification index of $A$, and let $L_k$ be the log structure on $\text{Spec}(k)$ associated with the pre-log structure $\mathbb{N} \rightarrow k$ sending $1 \mapsto 0$. Put $e' := pe/(p - 1)$. Then for $1 \leq q < e'$, there are isomorphisms
\[
\mathcal{Y}_1^r / \mathcal{Y}_1^{r+1} \overset{\sim}{\longrightarrow} \begin{cases} \omega_{Y_1}^{r-1} / \mathcal{Y}_{Y_1}^{r-1} & (p | q), \\ \omega_{Y_1}^{-1} / \mathcal{Y}_{Y_1}^{r-2} & (p \not| q), \end{cases}
\]
\[
\mathcal{Y}_1^r / \mathcal{Y}_1^{r+1} \overset{\sim}{\longrightarrow} \omega_{Y_1}^{r-2} / \mathcal{Y}_{Y_1}^{r-1}.
\]
Here $\omega_{Y_1}^m$ denotes the differential module of $(Y, L_{Y_1})$ over $(\text{Spec}(k), L_k)$ ([K3] (1.7)), and $\mathcal{Y}_{Y_1}^m$ (resp. $\mathcal{Y}_{Y_1}^{r-2}$) denotes the image of $d : \omega_{Y_1}^{m-1} \rightarrow \omega_{Y_1}^m$ (resp. the kernel of $d : \omega_{Y_1}^m \rightarrow \omega_{Y_1}^{m+1}$).

(4) Under the same assumption and notation as in (3), we have $\mathcal{Y}_1^0 \mathcal{Y}_1^r = \mathcal{Y}_1^r = 0$ for $q \geq e'$.

Proof. Note that the irreducible components of $D$ are semistable families around the fibers of characteristic $p$ by the assumption that $Y \cup D$ has normal crossings on $X$. The assertions (1) and (2) are reduced to the case that $X$ is smooth over $S$ and that $D = \emptyset$ (i.e., the Bloch-Kato theorem) by Tsuji’s trick in [Ts2] Proof of Theorem 5.1 and a variant of Hyodo’s lemma [Hy1] Lemma 3.5, whose details will be explained in a forthcoming paper [KSS]. The assertion (4) follows from [BK1] Lemma 5.1.

We prove (3). Let $\pi \in A$ be the fixed prime element. Let $\pi \in L_{Y_n}$ be the image of $\pi$, and let $[\pi] \subset L_{Y_n}$ be the subsheaf of monoids generated by $\pi$. The quotient $L_{Y_n}/[\pi]$ is a subsheaf of monoids of $\mathcal{O}_Y$ (with respect to the multiplication of functions) generated by $\mathcal{O}_Y^r$ and local equations defining $D$ and irreducible components of $Y$. There is a surjective homomorphism
\[
\delta_m : \mathcal{O}_Y \otimes (L_{Y_n}/[\pi])^p \otimes m \longrightarrow \omega_{Y_n}^m,
\]
defined by the local assignment
\[
z \otimes y_1 \otimes \cdots \otimes y_m \longmapsto z \cdot d \log(y_1) \wedge \cdots \wedge d \log(y_m),
\]
with $z \in \mathcal{O}_Y$ and each $y_i \in (L_{Y_n}/[\pi])^p$. The kernel of $\delta_m$ is generated by local sections of the following forms (cf. [Hy1] Lemma 2.2):
(1) \( z \otimes y_1 \otimes \cdots \otimes y_m \) such that \( y_s \) belongs to \( \mathcal{O}_{\text{Spec}(k)}^X \) for some \( 1 \leq s \leq m \).

(2) \( z \otimes y_1 \otimes \cdots \otimes y_m \) such that \( y_s = y_t \) for some \( 1 \leq s < t \leq m \).

(3) \( \sum_{i=1}^t (a_i \otimes a_i \otimes y_1 \otimes \cdots \otimes y_{m-1}) = \sum_{j=1}^\ell (b_j \otimes b_j \otimes y_1 \otimes \cdots \otimes y_{m-1}) \) with each \( a_i, b_j \in L_{Y, r} \) such that the sums \( \sum_{i=1}^t a_i \) and \( \sum_{j=1}^\ell b_j \) taken in \( \mathcal{O}_Y \) belong to \( L_{Y, r} \) and satisfy \( \sum_{i=1}^t a_i = \sum_{j=1}^\ell b_j \).

Hence the assertion follows from the arguments in loc. cit. p. 551.

We define the étale subsheaf \( FM_r^e \subset M_r^e \) as the part generated by \( \mathfrak{P}^1 M_r^e \) and the image of \((i^* h_* \mathcal{O}_{X_D}^e)^{\otimes r} \), where \( h \) denotes the open immersion \( X - D \hookrightarrow X \). By Theorem 3.3(2), Proposition 2.2 and the same arguments as in [Sa2] §3.4, we obtain the following theorem:

**Theorem 3.4** There are short exact sequences of sheaves on \( Y_{\text{ét}} \)

\[
0 \rightarrow FM_n^e \rightarrow M_n^e \xrightarrow{\sigma} \nu_{(Y, D \cap Y)_n}^{-1} \rightarrow 0,
0 \rightarrow \mathfrak{P}^1 M_n^e \rightarrow FM_n^e \xrightarrow{\tau} \nu_{(Y, D \cap Y)_n}^{-1} \rightarrow 0,
\]

where \( \sigma \) is induced by the boundary map of Galois cohomology groups due to Kato [K1], and \( \tau \) is given by the local assignment

\[
\{a_1, a_2, \ldots, a_r\} \mapsto d\log(\overline{a_1} \otimes \overline{a_2} \otimes \cdots \otimes \overline{a_r}).
\]

Here \( a_1, a_2, \ldots, a_r \) are local sections of \( i^* h_* \mathcal{O}_{X_D}^e \) and for \( \alpha \in i^* h_* \mathcal{O}_{X_D}^e, \) \( \pi \) denotes its residue class in \( g_* \mathcal{O}_Y^e \).

Now we define the \( p \)-adic étale Tate twists.

**Definition 3.5** For \( n \geq 1 \) and \( r \in \mathbb{Z} \), we define a cochain complex \( C_n(r)^{\bullet}_{(X, D)} \) of sheaves on \( X_D \) as follows.

(1) For \( r = 0 \), we define \( C_n(0)^{\bullet}_{(X, D)} := \mathbb{Z}/p^n \), the constant sheaf \( \mathbb{Z}/p^n \) placed in degree 0. For \( r < 0 \), we define \( C_n(r)^{\bullet}_{(X, D)} := j_* \mathcal{H}om_U (\mu_{p^n}^{\otimes r}, \mathbb{Z}/p^n) \), the sheaf \( j_* \mathcal{H}om_U (\mu_{p^n}^{\otimes r}, \mathbb{Z}/p^n) \) placed in degree 0.

(2) Assume \( r \geq 1 \), and let \( \mathcal{F}^e \) be the Godement resolution of \( \mu_{p^n}^{\otimes r} \) on \( U_{\text{ét}} \). We define \( C_n(r)^{\bullet}_{(X, D)} \) as

\[
\begin{align*}
\sigma^n_r : & \quad \ker(d : j_* \mathcal{F}^e \rightarrow j_* \mathcal{F}^e) \\
& \quad \xrightarrow{\sigma^n_r} j_* \mathcal{F}^e \\
& \quad \xrightarrow{\tau^n_r} \nu_{(Y, D \cap Y)_n}^{-1} \rightarrow 0,
\end{align*}
\]

where \( j_* \mathcal{F}^e \) is placed in degree 0 and \( i_* \nu_{(Y, D \cap Y)_n}^{-1} \) is placed in degree \( r + 1 \). The last arrow \( \sigma^n_r \) is defined as the composite map

\[
\sigma^n_r : \quad \ker(d : j_* \mathcal{F}^e_U \rightarrow j_* \mathcal{F}^e_U) \xrightarrow{R^* j_* \mu_{p^n}^{\otimes r} \xrightarrow{i_* \pi} i_* \nu_{(Y, D \cap Y)_n}^{-1}},
\]

and \( \sigma \) denotes the surjective map in Theorem 3.4.
We often write $\Sigma_n(r)(X,D)$ for $C_n(r)(X,D)$ regarded as an object of $D^b(X_{et},\mathbb{Z}/p^n)$. When $D = \emptyset$, we often write $C_n(r)_X$ and $\Sigma_n(r)_X$ for $C_n(r)(X,\emptyset)$ and $\Sigma_n(r)(X,\emptyset)$, respectively.

**Proposition 3.6** For $r \geq 0$, $\Sigma_n(r)(X,D)$ is concentrated in $[0,r]$, and there is a distinguished triangle in $D^b(X_{et},\mathbb{Z}/p^n)$

$$i_*\nu_{(Y,D\cap Y),n}^{r-1} \xrightarrow{\tau} \Sigma_n(r)(X,D) \xrightarrow{\tau_{\leq r}Rj_*\mu_{p^n}^{\otimes r}} i_*\nu_{(Y,D\cap Y),n}^{r-1}.$$

**Proof.** The first assertion follows from the surjectivity of $\sigma^r_n$ in the definition of $C_n(r)(X,D)$. The second assertion is straight-forward. \hfill \Box

**Remark 3.7** Proposition 3.6 implies that $\Sigma_n(r)(X,D)$ defined here agrees with that in [Sa2] §4 by a unique isomorphism compatible with the identity map of $\mu_{p^n}^{\otimes r}$ on $U$ (loc. cit. Lemma 4.2.2). Although we assumed that the residue fields of $\Lambda$ of characteristic $p$ are perfect in loc. cit., the results in loc. cit. §4–§7.2 hold true without this assumption by results of Shiho [Sh] Theorems 3.2, 4.1 and the compatibility result in [AS] Remark 7.3 (1).

**Proposition 3.8** The complex $C_n(r)(X,D)$ is contravariantly functorial in the pair $(X,D)$. Here a morphism of pairs $(X,D) \to (X',D')$ means a morphism of schemes $f : X \to X'$ satisfying $f(X - D) \subset X' - D'$.

**Proof.** The case $r \leq 0$ is clear. As for the case $r \geq 1$, it is enough to show that the map

$$i_*\sigma : R^rj_*\mu_{p^n}^{\otimes r} \longrightarrow i_*\nu_{(Y,D\cap Y),n}^{r-1}$$

is contravariant in $(X,D)$. Let $f : (X,D) \to (X',D')$ be a morphism of pairs, and consider the following diagram of immersions:

$$Y' \xleftarrow{i} X' \xrightarrow{j'} U' := X' - D',$$

where $Y'$ denotes the union of the fibers of $X' \to S$ of characteristic $p$. By the first exact sequence in Theorem 3.4, $\sigma'$ ($:= \sigma$ for $(X',D')$) is surjective and $\text{Ker}(i_*\sigma')$ maps into $\text{Ker}(i_*\sigma)$ under the base-change map

$$f^* : f^* R^rj_*\mu_{p^n}^{\otimes r} \longrightarrow R^rj_*\mu_{p^n}^{\otimes r}.$$

Hence this map induces a pull-back map

$$f^* : f^* i_*\nu_{(Y,D\cap Y),n}^{r-1} \longrightarrow i_*\nu_{(Y,D\cap Y),n}^{r-1} \quad (3.8.1)$$

These maps are obviously compatible with $\sigma'$s and satisfy transitivity. Thus we obtain the proposition. \hfill \Box
Corollary 3.9  (1) Let $V$ be the category whose objects are schemes $X$ as in Setting 3.1 and whose morphisms are morphisms of schemes. Then the complexes $C_{n}(r)^{•}_{X} = C_{n}(r)^{•}_{(X,∅)}$ with $X \in \text{Ob}(V)$ form a complex $C_{n}(r)^{•}$ of sheaves on the big étale site $V_{\text{ét}}$.

(2) The Godement resolution $G_{n}(r)^{•}_{(X,D)}$ on $X_{\text{ét}}$ of $C_{n}(r)^{•}_{(X,D)}$ is contravariantly functorial in $(X,D)$.

Remark 3.10 The object $\mathfrak{T}_{n}(r)_{(X,D)}$ is also contravariantly functorial in the pair $(X,D)$. More precisely, for a morphism of pairs $f : (X,D) \to (X',D')$, there is a natural morphism

$$f^{•} : f^{•}\mathfrak{T}_{n}(r)_{(X',D')} \to \mathfrak{T}_{n}(r)_{(X,D)} \quad \text{in} \quad D^{b}(X_{\text{ét}},\mathbb{Z}/p^{n})$$

by Proposition 3.8, which is, in fact, the unique morphism that extends the pull-back isomorphism of $\mu_{p^{n}}^{\otimes}$ for $U \to U'$ (cf. [Sa2] Proposition 4.2.8).

Remark 3.11 Let $V$ and $C_{n}(r)^{•}$ be as in Corollary 3.9, and let $\mathfrak{T}_{n}(r)$ be the complex $C_{n}(r)^{•}$ regarded as an object of the derived category $D^{b}(V_{\text{ét}},\mathbb{Z}/p^{n})$. Let $V' \subset V$ be the full subcategory consisting of schemes $X \in \text{Ob}(V)$ with $p^{-1} \in \Gamma(X,O_{X})$. The following facts will be useful later in §5:

(1) There exists a unique product structure

$$\mathfrak{T}_{n}(q) \otimes^{L} \mathfrak{T}_{n}(r) \longrightarrow \mathfrak{T}_{n}(q + r) \quad \text{in} \quad D(V_{\text{ét}},\mathbb{Z}/p^{n})$$

that extends the isomorphism $\mu_{p^{n}}^{\otimes q} \otimes \mu_{p^{n}}^{\otimes r} \cong \mu_{p^{n}}^{\otimes q + r}$ on the big étale site $(V')_{\text{ét}}$, which follows from the same arguments as in [Sa2] Proposition 4.2.6.

(2) There exists a unique isomorphism

$$\mathfrak{G}_{n} \otimes^{L} \mathbb{Z}/p^{n}[-1] \cong \mathfrak{T}_{n}(1) \quad \text{in} \quad D(V_{\text{ét}},\mathbb{Z}/p^{n})$$

that extends the canonical isomorphism $\mathfrak{G}_{n} \otimes^{L} \mathbb{Z}/p^{n}[-1] \longrightarrow \mu_{p^{n}}$ on $(V')_{\text{ét}}$, which follows from the same arguments as in loc. cit. Proposition 4.5.1.

Theorem 3.12 When $D$ is regular, there is a canonical morphism

$$\delta : \mathfrak{T}_{n}(r)_{(X,D)} \longrightarrow \alpha_{•}\mathfrak{T}_{n}(r-1)_{D}[-1] \quad \text{in} \quad D^{b}(X_{\text{ét}},\mathbb{Z}/p^{n})$$

fitting into a distinguished triangle

$$\alpha_{•}\mathfrak{T}_{n}(r-1)_{D}[-2] \xrightarrow{\alpha_{•}} \mathfrak{T}_{n}(r)_{X} \xrightarrow{\beta_{•}} \mathfrak{T}_{n}(r)_{(X,D)} \xrightarrow{\delta} \alpha_{•}\mathfrak{T}_{n}(r-1)_{D}[-1], \quad (3.12.1)$$

where $\alpha$ denotes the closed immersion $D \hookrightarrow X$, and $\beta$ denotes the natural morphism of pairs $(X,D) \to (X,∅)$. The arrow $\alpha_{•}$ denotes the Gysin morphism [Sa2] Theorem 6.1.3.
Proof. The case $r < 0$ immediately follows from the absolute purity [FG]. To prove the case $r \geq 0$, we first construct the morphism $\delta$. Consider a diagram of immersions

\[
\begin{array}{ccc}
Y & \xrightarrow{i} & X \\
\downarrow \alpha & & \downarrow \alpha \\
E & \xrightarrow{\epsilon} & D
\end{array}
\]

There is a distinguished triangle on $X[p^{-1}]_{et}$

\[
v_*\mu_{p^n}^{(r-1)}[-2] \xrightarrow{u_*} \mu_{p^n}^{(r)} \xrightarrow{u^*} Ru_*\mu_{p^n}^{(r)} \xrightarrow{\delta_1} v_*\mu_{p^n}^{(r-1)}[-1],
\]

where $\delta_1$ is defined as the composite

\[
\delta_1 : Ru_*\mu_{p^n}^{(r)} \xrightarrow{d^\loc} v_*Rv^!\mu_{p^n}^{(r)}[1] \xleftarrow{} v_*\mu_{p^n}^{(r-1)}[-1]
\]

and $d^\loc$ denotes the connecting morphism of a localization sequence. We used the absolute purity [FG] for the last isomorphism. Applying $Rw_*$, we get a distinguished triangle on $X_{et}$

\[
\alpha_*R\varphi_*\mu_{p^n}^{(r-1)}[-2] \xrightarrow{u_*} Rw_*\mu_{p^n}^{(r)} \xrightarrow{u^*} Rj_*\mu_{p^n}^{(r)} \xrightarrow{\delta_2} \alpha_*R\varphi_*\mu_{p^n}^{(r-1)}[-1].
\]  

(3.12.2)

Consider a diagram

\[
\begin{array}{ccc}
\Sigma_n(r)(X,D) & \xrightarrow{t} & \tau_{\leq r} Rj_*\mu_{p^n}^{(r)} \\
\downarrow \delta & & \downarrow \delta_3 = \tau_{\leq r}(\delta_2) \\
\alpha_\Sigma_n(r-1)(D[-1]) & \xrightarrow{\tau_{\leq r}(\alpha_*R\varphi_*\mu_{p^n}^{(r-1)}[-1])} & \gamma_*\nu_{E,n}^{-2}[-r],
\end{array}
\]

where the lower row is a part of a distinguished triangle (cf. Proposition 3.6 for $(D, \emptyset)$) and $\gamma$ denotes the composite morphism $\alpha \circ \iota' : E \hookrightarrow X$. Since $\Sigma_n(r)(X,D)$ is concentrated in $[0, r]$, we see that the composite $b' \circ \delta_3 \circ t$ is zero by Theorem 3.4 and a simple computation on symbols. On the other hand, we have

\[
\text{Hom}_{D^p(X_{et}, E/p^n)}(\Sigma_n(r)(X,D), \gamma_*\nu_{E,n}^{-2}[-r-1]) = 0,
\]

again by the fact that $\Sigma_n(r)(X,D)$ is concentrated in $[0, r]$. Hence there exists a unique morphism $\delta$ fitting into the above diagram (cf. [Sa2] Lemma 2.1.2(1)), which is the desired morphism. Finally the triangle (3.12.1) is distinguished by (3.12.2) and a commutative diagram with exact rows on $X_{et}$ ($\gamma = \alpha \circ \iota'$)

\[
\begin{array}{ccc}
R^*w_*\mu_{p^n}^{(r)} & \xrightarrow{\delta_3} & \alpha_*R^{r-1}\varphi_*\mu_{p^n}^{(r-1)} \xrightarrow{0} \\
\downarrow \sigma_X & & \downarrow \sigma_{(X,D)} \\
0 & \xrightarrow{\iota_*\nu_{Y,n}^{-1}} & \iota_*\nu_{(Y,E),n}^{-1} \xrightarrow{0} \\
\end{array}
\]

\[
\begin{array}{ccc}
\end{array}
\]

\textbf{Documenta Mathematica} 18 (2013) 177–247
where the surjectivity of $\delta_3$ in the upper row follows from Theorem 3.3 (1) for $(D, \emptyset)$, and the exactness of the lower row follows from (2.1.1).

\[ \square \]

\textbf{Remark 3.13} Let $\zeta_p$ be a primitive $p$-th root of unity, and let $A'$ be the normalization of $A[\zeta_p]$. Then all the definitions and results for the pair $(X, D)$ in this section are extended to the scalar extension $(X \otimes_A A', D \otimes_A A')$. Indeed, Theorem 3.3 (1) and (2) will be proved in [KSS] for this generalized situation. One can check Theorem 3.3 (3) and (4) for $(X \otimes_A A', D \otimes_A A')$ by the same arguments as for $(X, D)$. See [Sa2] §3.5 for an argument to extend Theorem 3.4.

4 Dold-Thom isomorphism

Let $S, p$ and $X$ be as in Setting 3.1, and let $n$ and $r$ be integers with $n \geq 1$. In this section we prove the Dold-Thom isomorphism for $p$-adic étale Tate twists. Let $E$ be a vector bundle of rank $a + 1$ on $X$, and let $f : \mathbb{P} := \mathbb{P}(E) \to X$ be the associated projective bundle, which is a projective smooth morphism of relative dimension $a$.

Let $\mathcal{O}(1)_E$ be the tautological invertible sheaf on $\mathbb{P}$, and let $\xi \in H^2(\mathbb{P}, \mathfrak{T}_n(1)_{\mathbb{P}})$ be the value of the first Chern class $c_1(\mathcal{O}(1)_E) \in H^1(\mathbb{P}, \mathcal{O}_{\mathbb{P}})$ under the connecting map associated with the Kummer distinguished triangle.

\[ \mathcal{O}_{\mathbb{P}} \to \mathcal{O}_{\mathbb{P}} \to \mathfrak{T}_n(1)_{\mathbb{P}}[1] \to \mathcal{O}_{\mathbb{P}}[1] \]

(cf. [Sa2] Proposition 4.5.1). The composite morphisms

\[ \mathfrak{T}_n(r - q)X[-2q] \xrightarrow{f^*} Rf_* \mathfrak{T}_n(r - q)_\mathbb{P}[-2i] \xrightarrow{-\cup \xi} Rf_* \mathfrak{T}_n(r)_\mathbb{P} \]

induce a canonical morphism

\[ \gamma_E : \bigoplus_{q=0}^a \mathfrak{T}_n(r - q)X[-2q] \to Rf_* \mathfrak{T}_n(r)_\mathbb{P} \quad \text{in} \quad D^b(X_\text{ét}, \mathbb{Z}/p^n). \]

\textbf{Theorem 4.1 (Dold-Thom isomorphism)} $\gamma_E$ is an isomorphism.

\textit{Proof.} $\gamma_E$ is an isomorphism outside of $Y$ by [M] VI Theorem 10.1. The case $r < 0$ follows from this fact and the proper base-change theorem. To prove the case $r \geq 0$, we consider a diagram of schemes

\[ \begin{array}{ccc}
  P & \xrightarrow{\gamma} & \mathbb{P} \\
  g \downarrow & \square & \downarrow f \\
  Y & \xrightarrow{i} & X \xrightarrow{j} X[p^{-1}].
\end{array} \]

We have to show that $i^*(\gamma_E)$ is an isomorphism:

\[ i^*(\gamma_E) : \bigoplus_{q=0}^a i^* \mathfrak{T}_n(r - q)X[-2q] \xrightarrow{\sim} Rg_* i^* \mathfrak{T}_n(r)_\mathbb{P}, \quad (4.1.1) \]
where we identified $i^* Rf_* \Sigma_n(r)_{\mathbb{F}}$ with $Rg_* \gamma^* \Sigma_n(r)_{\mathbb{F}}$ by the proper base-change theorem. By a standard norm argument (cf. [Sa2] §10.3) using Bockstein triangles (loc. cit. §4.3), we are reduced to the case that $n = 1$ and that $\mathcal{I}(X, \mathcal{O}_X)$ contains a primitive $p$-th root of unity (see Remark 3.13). We need the following lemma:

**Lemma 4.2** Let $\xi \in H^1(P, \lambda_{P,1}^1)$ be the image of $\xi$ under the pull-back map

$$\gamma^*: H^2(P, \Sigma_1(1)_{\mathbb{F}}) \longrightarrow H^1(P, \lambda_{P,1}^1)$$

(cf. [Sa2] Proposition 4.4.10). Then there are isomorphisms in $D^b(Y_{\text{et}}, \mathbb{Z}/p)$

\[
\bigoplus_{q=0}^{\alpha} \xi^q \cup - : \bigoplus_{q=0}^{\alpha} \lambda_{Y,1}^{r-q}[-q] \xrightarrow{\sim} Rg_* \lambda_{P,1}^1 \tag{1}
\]

\[
\bigoplus_{q=0}^{\alpha} \xi^q \cup - : \bigoplus_{q=0}^{\alpha} \nu_{Y,1}^{r-q}[-q] \xrightarrow{\sim} Rg_* \nu_{P,1}^r \tag{2}
\]

\[
\bigoplus_{q=0}^{\alpha} \xi^q \cup - : \bigoplus_{q=0}^{\alpha} \omega_{Y}^{r-q}[-q] \xrightarrow{\sim} Rg_* \omega_{P}^q \tag{3}
\]

\[
\bigoplus_{q=0}^{\alpha} \xi^q \cup - : \bigoplus_{q=0}^{\alpha} \mathcal{Z}_Y^{r-q}[-q] \xrightarrow{\sim} Rg_* \mathcal{Z}_P^r. \tag{4}
\]

Here $\mathcal{Z}_Y^m$ (resp. $\mathcal{Z}_P^m$) denotes the kernel of $d : \omega_Y^m \rightarrow \omega_Y^{m+1}$ (resp. $\omega_P^m \rightarrow \omega_P^{m+1}$).

**Proof of Lemma 4.2.** Note that $\xi$ agrees with the first Chern class of the tautological invertible sheaf on $P = \mathbb{P}(i^*E)$. Since the problems are étale local on $Y$, we may assume that $Y$ is simple. If $Y$ is smooth, then (1) and (2) are due to Gros [Gr1] I Théorème 2.1.11. The general case is reduced to the smooth case by [Sa1] Proposition 3.2.1, Corollary 2.2.7. As for (3), since we have

$$Rg_* \omega_P^{r-q} \simeq \bigoplus_{q=0}^{r} Rg_* (\Omega^q_{P/Y} \otimes \mathcal{O}_Y) \omega_Y^{r-q} \simeq \bigoplus_{q=0}^{r} (Rg_* \Omega^q_{P/Y}) \otimes_{\mathcal{O}_Y} \omega_Y^{r-q}$$

by projection formula, the assertion follows from the isomorphisms

$$\xi^q \cup - : \mathcal{O}_Y [-q] \xrightarrow{\sim} Rg_* \Omega^q_{P/Y} \quad (0 \leq q \leq \alpha).$$

(4) follows from the same arguments as for [Gr1] I (2.2.3). \qed

We return to the proof of (4.1.1) for $r \geq 0$. The case $r = 0$ follows from Lemma 4.2(1) with $r = 0$. To prove the case $r > 1$, we use the objects $\mathcal{K}(r-q)_{X} \in D^b(Y_{\text{et}}, \mathbb{Z}/p)$ and $\mathcal{K}(r)_{P} \in D^b(P_{\text{et}}, \mathbb{Z}/p)$ defined in [Sa2] Lemma 10.4.1, which fit into distinguished triangles

$$\mathcal{K}(r-q)_{X}[-1] \rightarrow \mu^\vee \otimes^L i^* \Sigma_1(r-q-1)_{X} \rightarrow i^* \Sigma_1(r-q)_{X} \rightarrow \mathcal{K}(r-q)_{X},$$

$$\mathcal{K}(r)_{P}[-1] \rightarrow g^* \mu^\vee \otimes^L \gamma^* \Sigma_1(r-1)_{P} \rightarrow \gamma^* \Sigma_1(r)_{P} \rightarrow \mathcal{K}(r)_{P}.$$
Here $\mu'$ denotes the constant sheaf $i^*j_*\mu_p(z/p)$ on $Y_\et$ and the central arrows are induced by the product structure of Tate twists. By induction on $r \geq 0$, our task is to show that the morphism

$$
\bigoplus_{q=0}^a \xi^q \cup - : \bigoplus_{q=0}^a K(r-q)_X[-2q] \to Rg_*K(r)_P
$$

(4.2.1)

is an isomorphism, where we have used the pull-back morphisms

$$
f^* : K(r-q)_X \to K(r-q)_P \quad (0 \leq q \leq a)
$$

induced by the pull-back morphisms for Tate twists (loc. cit. Proposition 4.2.8, Lemma 2.1.2 (2)). By loc. cit. Lemma 10.4.1 (2), we have

$$
H_m(K(r-q)_X) \simeq \begin{cases} 
\mu' \otimes \nu_r-q-2 & (m = r - q - 1) \\
FM_{r-q}^m & (m = r - q) \\
0 & (\text{otherwise}) 
\end{cases}
$$

and similar facts holds for $K(r)_P$ (see §3 for $FM_n^q$). Therefore (4.2.1) is an isomorphism by Lemma 4.2 and Theorems 3.3 (3), (4) and 3.4 with $D = \emptyset$ (see also the projection formula in loc. cit. 4.4.10). This completes the proof of Theorem 4.1. □

The following corollary 4.3 follows immediately from Theorems 3.12, 4.1 and the projection formula ([Sa2] Corollary 7.2.4), which is a $p$-adic version of homotopy invariance and plays an important role in our construction of cycle class maps (see §7 below).

**Corollary 4.3** Let $E$ be a vector bundle on $X$ of rank $a$, and put $P = P(E \oplus 1)$, the projective completion of $E$. Let $P'$ be the projective bundle $P(E)$ regarded as the infinite hyperplane, and let $f : P \to X$ be the natural projection. Then the composite morphism

$$
\xi_n(r)_X \xrightarrow{f_*} Rf_*\xi_n(r)_P \xrightarrow{Rf_*} D^b(X_\et, \mathbb{Z}/p^n)
$$

is an isomorphism in $D^b(X_\et, \mathbb{Z}/p^n)$.

5 **Chern Class**

The main aim of this section is to construct the Chern class map (5.6.1) below. Let $S$ and $p$ be as in Setting 3.1, and let $\mathcal{V}$ be the category whose objects are $S$-schemes satisfying the conditions in Setting 3.1 for $X$ and whose morphisms are morphisms of schemes. Let $X_\star$ be a simplicial object in $\mathcal{V}$, i.e., a contravariant functor

$$
X_\star : \Delta^{op} \to \mathcal{V},
$$

where $\Delta$ denotes the simplex category. For a morphism $\gamma : [a] \to [b]$ in $\Delta$, we write

$$
\gamma^X : X_b \to X_a \quad (X_a := X_\star([a]))
$$
for $X_\star(\gamma)$, which is a morphism in $\mathcal{V}$. For $0 \leq i \leq a$, let $d^i$ be the coface map in $\Delta$:

$$d^i : [a] \rightarrow [a + 1], \quad j \mapsto \begin{cases} j & (0 \leq j < i) \\ j + 1 & (i \leq j \leq a). \end{cases}$$

For integers $0 \leq i \leq a$, we often write $d^i : X_{a + 1} \rightarrow X_a$

for $(d^i)^X$. See [Fr] §1 for the definition of the small étale site $(X_\star)_{\text{ét}}$ on $X_\star$.

**Definition 5.1**

(1) For $r \in \mathbb{Z}$, we define a complex $C_n(r)_{X_\star}^\bullet$ of sheaves on $(X_\star)_{\text{ét}}$ by restricting the complex $C_n(r)^\bullet$ on $\mathcal{V}_{\text{ét}}$, cf. Corollary 3.9. We will often write $T_n(r)_{X_\star}$ for the complex $C_n(r)_{X_\star}^\bullet$ regarded as an object of $D^b((X_\star)_{\text{ét}})$.

(2) We define a canonical morphism

$$\varrho : \mathbb{G}_m[-1] \rightarrow \mathcal{T}_n(1)_{X_\star} \quad \text{in} \quad D^b((X_\star)_{\text{ét}})$$

by the composite morphism

$$\mathbb{G}_m[-1] \rightarrow \mathbb{G}_m \otimes \mathbb{Z}/p^n[-1] \xrightarrow{\sim} \mathcal{T}_n(1)_{X_\star},$$

where the left arrow denotes the canonical morphism induced by $\mathbb{Z} \rightarrow \mathbb{Z}/p^n$ and the right arrow is the restriction of the isomorphism in Remark 3.11 (2).

We next review the following basic notions:

**Definition 5.2**

(1) A vector bundle over $X_\star$ is a morphism $f : E_\star \rightarrow X_\star$ of simplicial schemes such that $f_a : E_a \rightarrow X_a$ is a vector bundle for any $a \geq 0$ and such that the commutative diagram

$$\begin{array}{c}
E_b \\
\gamma^X \\
E_a
\end{array} \xrightarrow{f} \begin{array}{c}
X_b \\
\gamma^X \\
X_a
\end{array}$$

induces an isomorphism $E_b \cong \gamma^X E_a := E_a \times_{X_a} X_b$ of vector bundles over $X_a$ for any morphism $\gamma : [a] \rightarrow [b]$ in $\Delta$ (cf. [Gi2] Example 1.1).

(2) A regular closed immersion of simplicial schemes is a morphism $i : X_\star \rightarrow Y_\star$ such that $i_a : X_a \rightarrow Y_a$ is a regular closed immersion for any $a \geq 0$ and such that the diagram

$$\begin{array}{c}
X_b \\
\gamma^X \\
X_a
\end{array} \xrightarrow{i} \begin{array}{c}
Y_b \\
\gamma^Y \\
Y_a
\end{array}$$

is cartesian for any morphism $\gamma : [a] \rightarrow [b]$ in $\Delta$. An effective Cartier divisor $X_\star$ on $Y_\star$ is a regular closed immersion $X_\star \rightarrow Y_\star$ of pure codimension 1.
We now define the first Chern classes of effective Cartier divisors and line bundles.

**Definition 5.3**

1. For an effective Cartier divisor \( D \) on \( X \), we define the first Chern class \( c_1(D) \in H^1_D((X)_{\text{Zar}}, \mathcal{O}^\times) \) as the value of the first Chern class \( c_1(D) \in H^1((X)_{\text{ét}}, \mathcal{O}) \) under the composite map
   \[
   H^1_D((X)_{\text{Zar}}, \mathcal{O}^\times) \xrightarrow{\epsilon^*} H^1_D((X), \mathcal{O}_m) \xrightarrow{\varphi} H^2_D((X), T_n(1)),
   \]
   where \( \epsilon : (X)_{\text{ét}} \to (X)_{\text{Zar}} \) denotes the continuous map of small sites. The arrow \( \varphi \) denotes that in Definition 5.1 (2).

2. For a line bundle \( L \) on \( X \), we define the first Chern class \( c_1(L) \in H^2((X), T_n(1)) \) as the value of the isomorphism class \([L] \in H^1((X)_{\text{ét}}, \mathcal{O}_m)\) under the composite map
   \[
   H^1((X)_{\text{ét}}, \mathcal{O}_m) \xrightarrow{\epsilon^*} H^1((X), G^\text{m}) \xrightarrow{\varphi} H^2((X), T_n(1)).
   \]

The following proposition plays a key role in the proof of the Whitney sum formula in Proposition 5.5 (3) below.

**Proposition 5.4**

Let \( f : X \hookrightarrow X' \) be a regular closed immersion of simplicial objects in \( \mathcal{V} \) of pure codimension \( c \geq 1 \). Let \( r \) be a non-negative integer. Then there exists a Gysin morphism
   \[
gys_f : \mathfrak{T}_n(r)_{X'} \to Rf^!\mathfrak{T}_n(r+c)_{X'}[2c]
   \]
   in \( \mathcal{D}^+(((X)_{\text{ét}}, \mathcal{O}/\mathbb{Z}/p^n) \)

satisfying the following three properties:

(a) **(Consistency with the first Chern class)** If \( r = 1 \), then the value of \( 1 \in \mathbb{Z}/p^n = H^0(X, \mathfrak{T}_n(0)) \) under the Gysin map
   \[
gys_f : H^0(X, \mathfrak{T}_n(0)) \to H^2_F((X)_{\text{ét}}, \mathfrak{T}_n(1))
   \]
   agrees with the first Chern class \( c_1(X) \) in Definition 5.3 (1).

(b) **(Transitivity)** For another regular closed immersion \( g : X' \hookrightarrow X'' \) of simplicial objects in \( \mathcal{V} \) of pure codimension \( c' \geq 1 \), the composite morphism
   \[
   \mathfrak{T}_n(r)_{X'} \xrightarrow{Rf^!(\text{gys}_f)} Rf^!\mathfrak{T}_n(r+c)_{X'}[2c] \xrightarrow{Rf^g} Rf^g\mathfrak{T}_n(r+c+c')_{X''}[2c+2c'] \xrightarrow{R(g \circ f)^!} \mathfrak{T}_n(r+c+c')_{X''}[2(c+c')]
   \]
   agrees with \( \text{gys}_{g \circ f} \).
(c) (Projection formula) The following diagram commutes in $D((X_\ast)_{\text{et}}, \mathbb{Z}/p^n)$:

$$
\begin{array}{ccc}
Rf^!\mathcal{I}_n(q)X' \otimes \mathcal{I}_n(r)X & \xrightarrow{id \otimes \text{gys}_f} & Rf^!\mathcal{I}_n(q)X' \otimes \mathcal{I}_n(n + r)X' [2r] \\
\pi & \downarrow & \text{product} \\
\mathcal{I}_n(q + r)X & \xrightarrow{\text{gys}_f} & Rf^!\mathcal{I}_n(q + r + c)X' [2c],
\end{array}
$$

where the left vertical arrow $\pi$ is the composite morphism

$$Rf^!\mathcal{I}_n(q)X' \otimes \mathcal{I}_n(r)X \xrightarrow{f^* \otimes \text{id}} \mathcal{I}_n(q)X \otimes \mathcal{I}_n(r)X \xrightarrow{\text{product}} \mathcal{I}_n(q + r)X,$$

and the product structures on $\{\mathcal{I}_n(r)X, r \in \mathbb{Z}\}$ and $\{\mathcal{I}_n(r)X, r \in \mathbb{Z}\}$ are obtained from that in Remark 3.11.

Proof. Put $U_\ast := X_\ast \otimes \mathbb{Z}[p^{-1}]$ and $V_\ast := X'_\ast \otimes \mathbb{Z}[p^{-1}]$. Let $\varphi : U_\ast \to V_\ast$ be the regular closed immersion induced by $f$. By the absolute purity [FG] and the spectral sequence

$$E_1^{a,b} = H_{U_\ast}^b(V_\ast, \mu_p^\otimes \epsilon) \Longrightarrow H_{U_\ast}^{a+b}(V_\ast, \mu_p^\otimes \epsilon),$$

we have

$$H_{U_\ast}^{2e}(V_\ast, \mu_p^\otimes \epsilon) \simeq \text{Ker}(d_0^* - d_1^* : H_{U_\ast}^{2e}(V_\ast, \mu_p^\otimes \epsilon) \to H_{U_\ast}^{2e}(V_\ast, \mu_p^\otimes \epsilon)).$$

By the definition of regular closed immersions in Definition 5.2 (2), the cycle class $\text{cl}_{V_\ast}(U_0) \in H_{U_\ast}^{2e}(V_\ast, \mu_p^\otimes \epsilon)$ lies in the group on the right hand side, loc. cit. Proposition 1.1.3. We thus define the cycle class

$$\text{cl}_{V_\ast}(U_\ast) \in H_{U_\ast}^{2e}(V_\ast, \mu_p^\otimes \epsilon)$$

as the element corresponding to $\text{cl}_{V_\ast}(U_0)$. Since $\varphi^* \mu_p^\otimes \epsilon_{V_\ast} \simeq \mu_p^\otimes \epsilon_{U_\ast}$ on $(U_\ast)_{\text{et}}$, the cup product with $\text{cl}_{V_\ast}(U_\ast)$ defines a Gysin morphism

$$\text{gys}_\varphi : \mu_p^\otimes \epsilon_{U_\ast} \simeq \varphi^* \mu_p^\otimes \epsilon_{V_\ast} \xrightarrow{d_{V_\ast}(U_\ast) \cup -} R\varphi^! \mu_p^\otimes \epsilon_{V_\ast} [2c] \quad \text{in} \quad D^+((U_\ast)_{\text{et}}, \mathbb{Z}/p^n),$$

which satisfies the three properties (a)–(c) listed above (see loc. cit. Proposition 1.2.1 for (b)). We show that there exists a unique morphism

$$\text{gys}_f : \mathcal{I}_n(r)X \to Rf^!\mathcal{I}_n(r + c)X' [2c] \quad \text{in} \quad D^+((X_\ast)_{\text{et}}, \mathbb{Z}/p^n)$$

that extends $\text{gys}_\varphi$. Put

$$Y_\ast := X_\ast \otimes \mathbb{Z}/p\mathbb{Z}, \quad \mathcal{L} := \mathcal{I}_n(r)X, \quad \text{and} \quad \mathcal{M} := Rf^!\mathcal{I}_n(r + c)X' [2c].$$

and let $\alpha$ and $\beta$ be as follows:

$$U_\ast \xrightarrow{\beta} X_\ast \xrightarrow{\alpha} Y_\ast.$$
Consider the following diagram in $D^+(\mathcal{X}_*; \mathbb{Z}/p^n)$ whose lower row is distinguished:

$$
\begin{array}{ccc}
\mathcal{L} & \xrightarrow{\tau_{\leq r}} & R\beta_*\mu_{p^n}^\otimes \\
\downarrow R\beta_*(\text{gys}_*{\text{et}}) & & \downarrow R\beta_*\beta^*\mathcal{M} \\
\alpha_*\mathcal{M} & \xrightarrow{\alpha_*} & \mathcal{M} \xrightarrow{\beta_*} R\beta_*\beta^*\mathcal{M} \\
\end{array}
$$

(5.4.1)

Here the upper horizontal arrow is the canonical morphism (cf. Propositions 3.6 and 3.8), and the lower row is the localization distinguished triangle for $\mathcal{M}$ (cf. [Sa2] (1.9.2)). We have

$$
\tau_{\leq r}\alpha_*\mathcal{M} = 0
$$

(5.4.2)

by the purity in loc. cit. Theorem 4.4.7, which implies that

$$
\text{Hom}_{D^+(\mathcal{X}_*; \mathbb{Z}/p^n)}(\tau_{\leq r}R\beta_*\mu_{p^n}^\otimes, \alpha_*\mathcal{M}[1])
$$

$$
= \text{Hom}_{\text{Shv}(\mathcal{X}_*; \mathbb{Z}/p^n)}(R\beta_*\mu_{p^n}^\otimes, \alpha_*R^{r+1}\alpha^!\mathcal{M})
$$

where $\text{Shv}(\mathcal{X}_*; \mathbb{Z}/p^n)$ denotes the category of étale sheaves of $\mathbb{Z}/p^n$-modules on $\mathcal{X}_*$. By this fact and the compatibility fact in loc. cit. Theorem 6.1.1, one can easily check that the composite $(-\delta) \circ R\beta_*(\text{gys}_*)$ is zero in $D^+(\mathcal{X}_*; \mathbb{Z}/p^n)$. Therefore we obtain a unique morphism $\text{gys}_f$ that extends $\text{gys}_*$ again by (5.4.2) and by loc. cit. Lemma 2.1.2(1). The property (a) of $\text{gys}_f$ is straight-forward, and the property (b) follows from the uniqueness of $\text{gys}_f$. The property (c) follows from the same argument as for loc. cit. Corollary 7.2.4.

Following the method of Grothendieck [G] and Gillet [Gi1], we define Chern classes

$$
c(E_*) = (c_i(E_*))_{i \geq 0} \in \bigoplus_{i \geq 0} H^{2i}(\mathcal{X}_*, \tau(i))
$$

of a vector bundle $E_*$ over $\mathcal{X}_*$ as follows. Let $E_*$ be of rank $a$, and let $f$ be the natural projection $\mathbb{P}(E_*) \to \mathcal{X}_*$. Let $\xi \in H^2(\mathbb{P}(E_*), \tau(1))$ be the value of the first Chern class of the tautological line bundle on $\mathbb{P}(E_*)$, cf. Definition 5.3(2). Noting the Dold-Thom isomorphism

$$
\bigoplus_{i=1}^a H^{2i}(\mathcal{X}_*, \tau(i)) \simeq H^{2a}(\mathbb{P}(E_*), \tau(a)), \quad (b_i)_{i=1}^a \mapsto \sum_{i=1}^a f^*(b_i) \cup \xi^{a-i}
$$

(5.4.3)

obtained from Theorem 4.1 and [Gi1] Lemma 2.4, we define

$$
c_0(E_*) := 1 \quad \text{and} \quad c_i(E_*) := 0 \quad \text{for} \quad i > a,
$$

and define $c_i = c_i(E_*)$ for $i = 1, 2, \ldots, a$ by the equation

$$
\xi^a + f^*(c_1) \cup \xi^{a-1} + \cdots + f^*(c_{a-1}) \cup \xi + f^*(c_a) = 0
$$

in $H^{2a}(\mathbb{P}(E_*), \tau(a))$. 

---

Documenta Mathematica 18 (2013) 177–247
Moreover, the Chern classes \( c(E_*) \) are characterized by these three properties.

Proof. The properties (1) and (2) immediately follow from this definition of Chern classes. The last assertion on the uniqueness follows from the splitting principle of vector bundles, whose details are straight-forward and left to the reader.

We prove the property (3) using the arguments of Grothendieck in [G] p. 144 Theorem 1 (iii), as follows. Let \( \pi^*: D'_* \to X_* \) and \( \pi'^*: D''_* \to X_* \) be the (simplicial) flag schemes of \( E'_* \) and \( E''_* \), respectively, and put

\[
D_* := D'_* \times_X D''_*,
\]

which is identified with the flag scheme of \( \pi''_* E'_* \) over \( D''_* \). Let \( f: D_* \to X_* \) be the natural projection. Since the pull-back map

\[
f^*: H^{2i}(X_*, \mathbb{Z}_n(i)) \to H^{2i}(D_*, \mathbb{Z}_n(i)),
\]

is injective by (5.4.3), we may replace \( (X_*, E_*, E'_*, E''_*) \) with \( (D_*, f^* E_*, f^* E'_*, f^* E''_*) \) to assume that \( E_* \) has a filtration by subbundles

\[
E_* = E^0_* \supset E^1_* \supset \cdots \supset E^a_* = 0 \quad (a := \text{rank}(E_*))
\]

such that the quotient \( E^i_*/E^{i+1}_* \) is a line bundle over \( X_* \) for \( 0 \leq i \leq a-1 \) and such that \( E^b_* = E'_* \) for \( b = \text{rank}(E''_*) \). Now let

\[
g: X'_* := \mathbb{P}(E'_*) \to X_*
\]

Moreover, the Chern classes \( c(E_*) \) are characterized by these three properties.
be the projective bundle associated with $E_*$. Let $L_*$ be the tautological line bundle over $X' = \mathbb{P}(E_*)$ and let $s : X'_* \to g^*E_* \otimes L_* =: F_*$ be the section induced by the canonical inclusion $(L_*)^i \hookrightarrow g^*E_*$:

$$s : X'_* \to \mathbb{P}(X'_*) \to g^*E_* \otimes L_* = F_*.$$

Put $F_i^i := g^*E_i^i \otimes L$ and $V_+^i := s^{-1}(F_i^i)$ for $0 \leq i \leq a$. Then $V_+^a$ is empty because $s$ does not vanish. Moreover $V_+^i$ is a simplicial object in $\mathcal{V}$ and the section

$$s_i : V_+^i \to F_+^i \to (F_+^i/F_+^{i+1})|_{V_+^i}$$

meets the zero section transversally for $0 \leq i \leq a - 1$, cf. [G] p. 147. On the other hand, to prove the Whitney sum formula, it is enough to show

$$\prod_{i=0}^{m+n-1} c_i(F_+^i/F_+^{i+1}) = 0.$$

We are thus reduced to the following simplicial analogue of loc. cit. p.141 Lemma 2:

**Lemma 5.6** Let $X_*$ be a simplicial object in $\mathcal{V}$. Let $E_*$ be a vector bundle of rank $a$ over $X_*$. Let $(E_*^i)_{0 \leq i \leq a}$ be a descending filtration consisting of subbundles on $E_*$ such that $E_*^i$ has rank $a - i$. For $1 \leq i \leq a$, put

$$\xi_i := c_1(E_*^{i-1}/E_*^i) \in H^2(X_*, \mathbb{T}_n(1)).$$

Let $s : X_* \to E_*$ be a section of $E_* \to X_*$. For $0 \leq i \leq a$, put

$$V_*^i := s^{-1}(E_*^i), \quad L_*^i := (E_*^i/E_*^{i+1})|_{V_*^i} \quad \text{(restriction of } E_*^i/E_*^{i+1 \text{ onto } V_*^i),}$$

and let $s_i : V_*^i \to L_*^i$ be the section induced by $s$. Assume the following condition:

- $V_*^i$ is a simplicial object in $\mathcal{V}$ for $0 \leq i \leq a$, and $s_i$ intersects the zero section transversally for $0 \leq i \leq a - 1$.

Then we have

$$\text{cl}_{X_*}(V_*^a) = \prod_{i=1}^a \xi_i \quad \text{in} \quad H^{2a}(X_*, \mathbb{T}_n(a)),$$

where $\text{cl}_{X_*}(V_*^a)$ denotes the value of 1 under the Gysin map

$$\mathbb{Z}/p^n = H^0(V_*^a, \mathbb{T}_n(0)) \to H^{2a}(X_*, \mathbb{T}_n(a)).$$

One can easily check this lemma by the properties of the Gysin morphisms in Proposition 5.4 and the arguments in loc. cit. p.141 Lemma 2. This completes the proof of Proposition 5.5.

Now let $X$ be a scheme which belongs to $\mathcal{V}$. Applying the construction of Chern classes to the case $X_* = B_s \text{GL}_{s,X}$ and $E_* = \text{universal rank } s$ bundle over $B_s \text{GL}_{s,X}$, we obtain Chern classes

$$c_j(E_*) \in H^{2j}(B_s \text{GL}_{s,X}, \mathbb{T}_n(j)) \quad (j \geq 0),$$

**Documenta Mathematica** 18 (2013) 177–247
which are called the universal rank $s$ Chern classes. On the other hand, let $I_n(j)^X$ be an injective resolution of the complex $C_n(j)^X$ on $X_{\text{ét}}$ defined in Definition 3.5, and consider the following complex of abelian sheaves on $X_{\text{Zar}}$:

$$
\cdots \to \epsilon_* I_n(j)^{2j-2} \to \epsilon_* I_n(j)^{2j-1} \to \epsilon_* I_n(j)^{2j} \to \ker(p^{2j}) \to \epsilon_* I_n(j)^{2j+1}.
$$

Here $\epsilon : X_{\text{ét}} \to X_{\text{Zar}}$ denotes the continuous map of small sites, and we regarded this sequence as a chain complex with the most right term placed in degree 0. We apply the Dold-Puppe construction [DP] to this complex to obtain a sheaf of simplicial abelian groups, which we denote by $K$. Let $\tau$ apply the Dold-Puppe construction [DP] to this complex to obtain a sheaf of simplicial abelian groups, which we denote by $K$. For a closed subset $Z$ of $X$ and non-negative integers $i, r \geq 0$, we define the Chern class map

$$
C_{r,i}^Z : K^Z(X) \to H_{Z}^{2r-i}(X, \mathbb{T}_n(r)) \tag{5.6.1}
$$

as the following composite map (cf. [Gi1] Definition 2.22):

$$
K^Z(X) \to H_{Z}^{1}(X_{\text{Zar}}, \mathbb{Z} \times \mathbb{Z}_\infty \mathbb{B}, \mathbb{GL}(\mathcal{O}_X)) \xrightarrow{pr} H_{Z}^{1}(X_{\text{Zar}}, \mathbb{Z}_\infty \mathbb{B}, \mathbb{GL}(\mathcal{O}_X))
$$

$$
\pi_1(\mathbb{Z}_\infty c_r) H_{Z}^{i-1}(X_{\text{Zar}}, \mathbb{Z}_\infty \mathbb{K}(\mathcal{O}_n(r), 2r)) \cong H_{Z}^{2r-i}(X_{\text{ét}}, \mathcal{T}_n(r)).
$$

Here $\mathbb{Z}_\infty$ denotes the Bousfield-Kan completion [BoK], and we have used the universal rank $s$ Chern class $c_r(E_s)$ for a sufficiently large $s$ to define the arrow $\pi_1(\mathbb{Z}_\infty c_r)$. See [Gi1] Proposition 2.15 for the first arrow and see loc. cit. p. 226 for the last isomorphism. The map $C_{r,i}^X$ agrees with $c_r$ for $X_s = X$ (constant simplicial scheme) defined before.

**Theorem 5.7**

1. $C_{r,i}^Z$ is contravariantly functorial in the pair $(X, Z)$, that is, for a morphism $f : X \to X'$ in $\mathcal{V}$ and a closed subset $Z' \subset X'$ with $f^{-1}(Z') \subset Z$, there is a commutative diagram

$$
\begin{array}{ccc}
K^Z_{r,i}(X') & \xrightarrow{C_{r,i}^{Z'}} & H_{Z}^{2r-i}(X', \mathcal{T}_n(r)) \\
\downarrow{f^*} & & \downarrow{f^*} \\
K^Z_{r,i}(X) & \xrightarrow{C_{r,i}} & H_{Z}^{2r-i}(X, \mathcal{T}_n(r)).
\end{array}
$$

2. $C_{r,i}^Z$ is additive for $i > 0$.

3. The induced Chern character

$$
\text{ch} : \bigoplus_{i \geq 0} K_i(X) \to \prod_{i,r \geq 0} H^i(X, \mathcal{T}_{Q_p}(r))
$$

with $H^i(X, \mathcal{T}_{Q_p}(r)) := \mathcal{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^i(X, \mathcal{T}_n(r))$ is a ring homomorphism.

**Proof.** (1) follows from the functoriality results in Proposition 5.5 (2) and Proposition 3.8. The assertion (2) follows from Proposition 5.5 (3) and [Gi1] Lemma 2.26. See loc. cit. Definition 2.34 and Proposition 2.35 for the assertion (3).
6 Purity along log poles

This and the next section are devoted to the construction of cycle class maps from higher Chow groups to $p$-adic étale Tate twists.

Let $k$ be a field of characteristic $p > 0$, and let $Y$ be a normal crossing variety over $k$. Let $D$ be a non-empty admissible divisor on $Y$, and let $Z$ be a reduced closed subscheme of $Y$ which has codimension $\geq c$ and contained in $D$. Let $i : Z \hookrightarrow Y$ be the natural closed immersion. In this section, we first prove the following purity result:

**Theorem 6.1 (Purity)** We have $R^q i_! \nu^r_{(Y,D),n} = 0$ for $q \leq c$.

See Theorem 6.5 below for a consequence of this theorem. Note that the assertion for $q = c$ does not follow directly from Gros' purity [Gr1] II Théorème 3.5.8, even when $Y$ is smooth. The case that $Y$ is smooth has been considered and proved independently by Mieda ([Mi1] Proof of Theorem 2.4, [Mi2]). Although the proof of Theorem 6.1 given below is essentially a variant of Gros’ proof of [Gr1] II Théorème 3.5.8, we include detailed computations for the convenience of the reader.

**Proof of Theorem 6.1.** Since the problem is étale local, we may assume that $Y$ is simple and that there exists a pair $(Y, D)$ satisfying the following (1) and (2):

1. $Y$ is smooth over $k$ and contains $Y$ as a normal crossing divisor,
2. $D$ is a normal crossing divisor on $Y$ such that $Y \cup D$ has normal crossings on $Y$ and such that $Y \cap D = D$.

Then we have a short exact sequence on $\mathcal{Y}_{\text{et}}$

$$0 \longrightarrow W_n \Omega^{r+1}_{(Y,D),\log} \longrightarrow W_n \Omega^{r+1}_{(Y \cup D),\log} \longrightarrow \nu^r_{(Y,D),n} \longrightarrow 0$$

(a variant of (2.1.1)), which reduces the assertion to the case that $Y$ is smooth over $k$ and that $D$ has normal crossings on $Y$. Furthermore, we may assume that $Z$ is regular of pure codimension $c$ by a standard dévissage argument. In what follows, we prove

$$R^q i_! W_n \Omega^r_{(Y,D),\log} = 0 \quad \text{for} \quad q \neq c + 1,$$

(6.1.1)

assuming that $Y$ is smooth over $k$ (and that $Z$ is regular and contained in $D$). By the short exact sequences on $Y_{\text{et}}$,

$$0 \longrightarrow W_{n-1} \Omega^r_{(Y,D),\log} \longrightarrow W_n \Omega^r_{(Y,D),\log} \longrightarrow \Omega^r_{(Y,D),\log} \longrightarrow 0,$$

$$0 \longrightarrow \Omega^r_{(Y,D),\log} \longrightarrow \mathcal{Z}^r_Y(\log D) \longrightarrow \Omega^r_Y(\log D) \longrightarrow 0$$

(cf. (2.1.1) and [Sa1] Corollary 2.2.5 (2), Lemma 2.4.6), it is enough to show that

$$R^q i_! \mathcal{Z}^r_Y(\log D) = 0 = R^q i_! \Omega^r_Y(\log D) \quad \text{for} \quad q \neq c,$$

(6.1.2)

and

$$1 - C : R^c i_! \mathcal{Z}^r_Y(\log D) \longrightarrow R^c i_! \Omega^r_Y(\log D) \quad \text{is injective.}$$

(6.1.3)
We define an ascending filtration $\mathcal{F}^i$ where we regarded the sheaves on the right hand side as sheaves on $\mathcal{Y}_r$. The assertion (6.1.2) follows from the smoothness of $\mathcal{Y}_r$ and the fact that $\mathcal{Y}_r$ is affine, and there exists a regular sequence $(t_1, \ldots, t_c) \in \mathcal{Y}_r$ such that the ideal $(t_1, \ldots, t_c) \subset \mathcal{O}_{\mathcal{Y}_r}$ defines $Z$ and such that $t_1, \ldots, t_c (1 \leq a \leq c)$ are uniformizers of the irreducible components of $D$. Moreover, $\mathcal{Y}_r$ is free over $\mathcal{O}_{\mathcal{Y}_r}$ and has a basis $\{dt_a\}_{a=1}^c$ which contains $dt_1, \ldots, dt_c$.

We prove here the following lemma.

**Lemma 6.2** We recall here the following standard fact (cf. [Gr1] II (3.3.6)):

For $j = 1, \ldots, c$, let $\sigma_j$ be the natural open immersion $\sigma_j : \mathcal{Y}_r[t_1^{-1}, \ldots, t_c^{-1}] \to \mathcal{Y}_r$. We have isomorphisms of sheaves on $\mathcal{Y}_r$.

\[
\tau : \mathcal{Y}_r[t_1^{-1}, \ldots, t_c^{-1}] \to \mathcal{Y}_r.
\]

For $j = 1, \ldots, c$, let $\rho_j$ be the natural open immersion $\rho_j : \mathcal{Y}_r[t_1^{-1}, \ldots, t_j^{-1}, t_{j+1}^{-1}, \ldots, t_c^{-1}] \to \mathcal{Y}_r$.

We recall here the following standard fact (cf. [Gr1] II (3.3.6)):

**Lemma 6.2** We have isomorphisms of sheaves on $\mathcal{Y}_{\text{et}}$

\[
R^c i_! \Omega_{\mathcal{Y}_r}^\tau (\log D) \simeq \tau_* \tau^* \Omega_{\mathcal{Y}_r}^\tau (\log D) / \sum_{j=1}^c \sigma_j , \sigma_j^* \Omega_{\mathcal{Y}_r}^\tau (\log D) (6.2.1)
\]

\[
= \tau_* \tau^* \Omega_{\mathcal{Y}_r}^\tau / \left( \sum_{j=1}^c \sigma_j , \sigma_j^* \Omega_{\mathcal{Y}_r}^\tau (\log D) + \sum_{j=a+1}^c \sigma_j , \sigma_j^* \Omega_{\mathcal{Y}_r}^\tau \right),
\]

\[
R^c i_! \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) \simeq \tau_* \tau^* \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) / \sum_{j=1}^c \sigma_j , \sigma_j^* \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) (6.2.2)
\]

\[
= \tau_* \tau^* \mathcal{Z}_{\mathcal{Y}_r}^\tau / \left( \sum_{j=1}^c \sigma_j , \sigma_j^* \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) + \sum_{j=a+1}^c \sigma_j , \sigma_j^* \mathcal{Z}_{\mathcal{Y}_r}^\tau \right),
\]

where we regarded the sheaves on the right hand side as sheaves on $\mathcal{Y}_{\text{et}}$ naturally.

We define an ascending filtration $\mathcal{F}_m (m \geq 0)$ on $\tau_* \tau^* \Omega_{\mathcal{Y}_r}$ as

\[
\mathcal{F}_m (\tau_* \tau^* \Omega_{\mathcal{Y}_r}) := \left\{ \frac{1}{(t_1 t_2 \cdots t_c)^m} \omega \in \tau_* \tau^* \Omega_{\mathcal{Y}_r} \mid \omega \in \Omega_{\mathcal{Y}_r} \right\}.
\]

Let $\mathcal{F}_m (R^c i_! \Omega_{\mathcal{Y}_r}^\tau (\log D))$ be the induced filtration, and let $\mathcal{F}_m (R^c i_! \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D))$ be its inverse image under the canonical map

\[
R^c i_! \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) \to R^c i_! \Omega_{\mathcal{Y}_r}^\tau (\log D) (6.2.3)
\]

induced by the natural inclusion $\mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) \hookrightarrow \Omega_{\mathcal{Y}_r}^\tau (\log D))$. Note that

\[
R^c i_! \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D) = \bigcup_{m=0}^{\infty} \mathcal{F}_m (R^c i_! \mathcal{Z}_{\mathcal{Y}_r}^\tau (\log D)).
\]

We prove here the following lemma.
Lemma 6.3  (1) The map (6.2.3) is injective.

(2) $\text{Fil}_m(R^{c_1} \mathcal{L}_Y^r (\log D))$ is generated by elements of the form
\[
\left[ \frac{1}{(t_1 t_2 \cdots t_c)^{pm}} \omega \right] \quad \text{with} \quad \omega \in \mathcal{L}_Y^r,
\]
where $[-]$ denotes the residue class in $\text{Fil}_m(R^{c_1} \mathcal{L}_Y^r (\log D))$ via (6.2.2).

(3) The kernel of the projection via (6.2.1)
\[
\text{Fil}_m(\tau_* \tau^* \Omega_Y^r) \longrightarrow \text{Fil}_m(R^{c_1} \Omega_Y^r (\log D))
\]
agrees with the subgroup
\[
\left\{ \sum_{j=1}^c \frac{1}{(t_1 \cdots t_{j-1} t_{j+1} \cdots t_c)^{pm}} \omega_j \mid \begin{array}{l}
\omega_j \in \Omega_Y^r (\log D_j) \quad (1 \leq j \leq a) \\
\omega_j \in \Omega_Y^r \quad (a < j \leq c)
\end{array} \right\},
\]
where $D_j \subset Y$ denotes the regular divisor defined by $t_j$ for $1 \leq j \leq a$.

Proof. We prove (1). By the short exact sequence
\[
0 \longrightarrow \mathcal{L}_Y^r (\log D) \longrightarrow \Omega_Y^r (\log D) \longrightarrow \mathcal{B}_Y^{r+1} (\log D) \longrightarrow 0,
\]
we have a long exact sequence on $\mathbb{Z}_{et}$
\[
\cdots \longrightarrow R^{c_1} \mathcal{B}_Y^{r+1} (\log D) \longrightarrow R^{c_1} \mathcal{L}_Y^r (\log D) \longrightarrow R^{c_1} \Omega_Y^r (\log D) \longrightarrow \cdots.
\]
The assertion follows from the smoothness of $Y$ and the fact that $\mathcal{B}_Y^{r+1} (\log D)$ is locally free over $(\mathcal{O}_Y)^p$. The assertion (2) is a consequence of (1), and (3) is straightforward.

We return to the proof of (6.1.3), and compute the map $1 - C$ in (6.1.3):
\[
1 - C : R^{c_1} \mathcal{L}_Y^r (\log D) \longrightarrow R^{c_1} \Omega_Y^r (\log D), \quad (6.3.1)
\]
using the filtration $\text{Fil}_\bullet$. Put
\[
\text{gr}_m(-) := \text{Fil}_m(-)/\text{Fil}_{m-1}(-).
\]
Since we have
\[
C\left( \frac{1}{(t_1 t_2 \cdots t_c)^{pm}} \omega \right) = \frac{1}{(t_1 t_2 \cdots t_c)^m} C(\omega) \quad \text{for} \quad \omega \in \mathcal{L}_Y^r,
\]
the Cartier operator preserves $\text{Fil}_\bullet$ (by Lemma 6.3 (2)) and induces a map
\[
\text{gr}_m(C) : \text{gr}_m(R^{c_1} \mathcal{L}_Y^r (\log D)) \longrightarrow \text{gr}_m(R^{c_1} \Omega_Y^r (\log D)).
\]
which is the zero map for \( m \geq 2 \). Hence we have

the kernel of (6.3.1) \( \subset \text{Fil}_1(\mathcal{R}^c i^! \mathcal{F}_Y^c(\log D)) \).

Let \( D_j \subset Y \) be as we defined in Lemma 6.3 (3) for \( 1 \leq j \leq a \). Fix an arbitrary \( \omega \in \mathcal{F}_Y^c \), and assume that

\[
\begin{align*}
x := \left[ \frac{1}{(t_1t_2 \cdots t_c)^p} \omega \right] \in \text{Fil}_1(\mathcal{R}^c i^! \mathcal{F}_Y^c(\log D))
\end{align*}
\]

belongs to the kernel of (6.3.1). To show (6.1.3), we have to prove that

\[
\omega = \sum_{j=1}^{c} t_j^p \eta_j \quad \text{for some} \quad \eta_j \in \Omega_Y^r(\log D_j) \quad (1 \leq j \leq a)
\]

\[
\eta_j \in \Omega_Y^r \quad (a < j \leq c)
\]

in \( \Omega_Y^r(\log D) \), which is equivalent to that \( x = 0 \) in \( \mathcal{R}^c i^! \mathcal{F}_Y^c(\log D) \) by Lemma 6.3 (1) and (6.2.1). Since \( x = C(x) \) in \( \text{Fil}_1(\mathcal{R}^c i^! \mathcal{F}_Y^c(\log D)) \) by assumption, we have

\[
\frac{1}{(t_1t_2 \cdots t_c)^p} \omega - \frac{1}{t_1t_2 \cdots t_c} C(\omega) = \sum_{j=1}^{c} \frac{1}{(t_1t_2 \cdots t_{j-1}t_{j+1} \cdots t_c)^p} \alpha_j
\]

in \( \tau \cdot \tau^* \Omega_Y^r \) for some \( \alpha_j \in \Omega_Y^r(\log D_j) \) (\( 1 \leq j \leq a \)) and \( \alpha_j \in \Omega_Y^r \) (\( a < j \leq c \)) by Lemma 6.3 (3). This implies

\[
\omega = (t_1t_2 \cdots t_c)^{p-1}C(\omega) + \sum_{j=1}^{c} t_j^p \alpha_j \quad \text{in} \quad \Omega_Y^r,
\]

and our task is to prove that

\[
(t_1t_2 \cdots t_c)^{p-1}C(\omega) = \sum_{j=1}^{c} t_j^p \zeta_j \quad \text{for some} \quad \zeta_j \in \Omega_Y^r(\log D_j) \quad (1 \leq j \leq a)
\]

\[
\zeta_j \in \Omega_Y^r \quad (a < j \leq c).
\]

(6.3.4)

Take a basis \( \{ dt_\lambda \}_{\lambda \in A} \) of \( \mathcal{F}_Y^c \) over \( \mathcal{O}_Y^c \) which contain \( dt_1, \ldots, dt_c \) (see the condition (\( \ast \))). Fix an ordering on \( A \) and let \( J \) be the set of all \( r \)-tuples \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_r) \) of elements of \( A \) satisfying

\[
\lambda_1 < \lambda_2 < \cdots < \lambda_r.
\]

For \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_r) \in J \), put

\[
dt_\lambda := dt_{\lambda_1} \wedge dt_{\lambda_2} \wedge \cdots \wedge dt_{\lambda_r} \in \Omega_Y^r.
\]

Using the basis \( \{ dt_\lambda \}_{\lambda \in J} \) of \( \Omega_Y^r \) over \( \mathcal{O}_Y^c \), we decompose \( C(\omega) \) as

\[
C(\omega) = \epsilon + \delta \quad (\epsilon, \delta \in \Omega_Y^r).
\]

(6.3.5)
Here $\epsilon$ is an $O_Y$-linear combination of $dt_\lambda$’s which contain $dt_j$ for some $1 \leq j \leq a$, and $\delta$ is an $O_Y$-linear combination of $dt_\lambda$’s which contain none of $dt_1, \ldots, dt_a$. We have
\[(t_1 t_2 \cdots t_c)^{p-1} \epsilon = \sum_{j=1}^{a} t_j^p \beta_j \text{ for some } \beta_j \in \Omega_Y^r(\log D_j) \quad (1 \leq j \leq a), \quad (6.3.6)\]
which implies (6.3.4) if $\delta = 0$. Otherwise, we proceed as follows. Put 
\[y := (t_2 t_3 \cdots t_c) t_1^{p-1} \delta \in \Omega_Y^r.
\]

Since $d\omega = 0$, the equalities (6.3.3) and (6.3.6) imply 
\[t_1^{p-2} dt_1 \wedge y = t_1^{p-1} dy + \sum_{j=1}^{c-1} t_j^p \beta'_j \text{ for some } \begin{cases} \beta'_{m} \in \Omega_Y^r(\log D_j) & (1 \leq j \leq a) \\ \beta'_j \in \Omega_Y^r(a < j \leq c) \end{cases} \quad (6.3.7)
\]

By this equality and the assumption on $\delta$, one can easily check that 
\[t_1^{p-2} dt_1 \wedge y = \sum_{j=2}^{c} t_j^p \beta''_j \text{ for some } \begin{cases} \beta''_{m} \in \Omega_Y^r(\log D_1) \\ \beta''_j \in \Omega_Y^r(2 \leq j \leq c) \end{cases} \quad (6.3.7)
\]
To proceed with the proof of (6.3.4), we need the following lemma:

**Lemma 6.4** Let $f$ and $g$ be the following $O_Y$-linear maps, respectively:
\[f : \Omega_Y^r \longrightarrow \Omega_Y^{r+1}, \quad z \mapsto dt_1 \wedge z,
\]
\[g : \Omega_Y^r(\log D_1) \longrightarrow \Omega_Y^{r+1}(\log D_1), \quad z \mapsto \frac{dt_1}{t_1} \wedge z.
\]
Then the following holds:

1. For $m \geq 1$, we have 
\[\operatorname{Im}(f) \cap \left( t_1^m \Omega_Y^{r+1}(\log D_1) + \sum_{j=2}^{c} t_j^m \Omega_Y^{r+1} \right) = t_1^m \operatorname{Im}(g) + \sum_{j=2}^{c} t_j^m \operatorname{Im}(f).
\]
2. For $m, n \geq 0$, we have 
\[t_1^m \Omega_Y^{r+1} \cap \left( \sum_{j=2}^{c} t_j^n \operatorname{Im}(f) \right) = \sum_{j=2}^{c} t_1^m t_j^n \operatorname{Im}(f).
\]
3. For $m \geq 0$, the sequence 
\[t_1^m \Omega_Y^{r-1} \xrightarrow{f} t_1^m \Omega_Y^r \xrightarrow{f} t_1^m \Omega_Y^{r+1}\]
is exact.
Proof. These assertions follow from linear algebra over $\mathcal{O}_Y$. The details are straightforward and left to the reader. □

By (6.3.7) and Lemma 6.4 (1) for $m = p$, we have

$$t^{p-2}_1 dt_1 \wedge y = t^{p-1}_1 dt_1 \wedge \gamma_1 + \sum_{j=2}^{c} t^{p}_j dt_1 \wedge \gamma_j$$  \hspace{1cm} (6.4.1)

for some $\gamma_1 \in \Omega^r_Y(\log D_1)$ and some $\gamma_j \in \Omega^r_Y$ $(2 \leq j \leq c)$. If $p = 2$, this equality implies

$$t^{p-2}_1 dt_1 \wedge y = t^{p-1}_1 dt_1 \wedge \left( t^{p}_1 \gamma_1 + \sum_{j=2}^{c} t^{p}_j \gamma_j \right).$$ \hspace{1cm} (6.4.2)

If $p \geq 3$, we obtain (6.4.2) from (6.4.1) by replacing $\gamma_2, \ldots, \gamma_c$ suitably in $\Omega^r_Y(2 \leq j \leq c)$, where we used Lemma 6.4 (2) for $(m,n) = (p,p-2)$. Noting that $t^{p}_1 \gamma_1$ and $t^{p}_j \gamma_j (2 \leq j \leq c)$ belong to $\Omega^r_Y$, we have

$$t^{p-2}_1 t^{p}_1 \gamma_1 + \sum_{j=2}^{c} t^{p}_j (t^{p-2}_1 \gamma_j)$$

by (6.4.2) and Lemma 6.4 (3) for $m = p - 2$. Thus we have

$$(t_1 t_2 \cdots t_c)^{p-1} \delta = t^{p-1}_1 y = t^{p}_1 \left( \frac{dt_1}{t_1} \wedge \vartheta + \gamma_1 \right) + \sum_{j=2}^{c} t^{p}_j (t^{p-2}_1 \gamma_j),$$

which implies (6.3.4) (see also (6.3.5), (6.3.6)). This completes the proof of (6.3.2), (6.1.3) and Theorem 6.1. □

**Theorem 6.5** Let $S, p$ and $X$ be as in Setting 3.1, and let $c$ be a positive integer. Let $D$ be a non-empty normal crossing divisor on $X$, and let $Z$ be a closed subset of $X$ which has codimension $\geq c$. Put $U := X - D$. Then we have

$$H^q_Z(X, \mathbb{T}_n(r)_{(X,D)}) \simeq \begin{cases} 0 & (q < r + c) \\ H^{q+c}_{Z \cap U}(U, \mathbb{T}_n(r)_{U}) & (q = r + c). \end{cases}$$ \hspace{1cm} (6.5.1)

In particular, when $Z$ has pure codimension $r$ on $X$, we have

$$H^q_Z(X, \mathbb{T}_n(r)_{(X,D)}) \simeq \begin{cases} 0 & (q < 2r) \\ \mathbb{Z}/p^n[Z^0 \cap U] & (q = 2r). \end{cases}$$ \hspace{1cm} (6.5.2)

where $\mathbb{Z}/p^n[Z^0 \cap U]$ means the free $\mathbb{Z}/p^n$-module generated by the set $Z^0 \cap U$.

*Proof.* Admitting (6.5.1), we obtain (6.5.2) from the purity of $\mathbb{T}_n(r)_{U}$ ([Sa2] Theorem 4.4.7, Corollary 4.4.9) and the absolute purity of $\mu^\infty_{(0)}$ on $U[p^{-1}]$ ([FG]). To show (6.5.1), we divide the problem into the following 4 cases:
(1) $Z \subset D \cap Y$  
(2) $Z \subset D$ and $Z \not\subset Y$

(3) $Z$ is arbitrary and $q < r + c$  
(4) $Z$ is arbitrary and $q = r + c$.

The case (1) follows from Theorems 3.3, 6.1 (see also Remark 3.13) and the same arguments as in [Sa2] Theorem 4.4.7. The case (2) follows from the case (1) and the same arguments as in loc. cit. Corollary 4.4.9. The case (3) also follows from similar arguments as for the previous cases. To prove the case (4), write $Z$ as the union of closed subsets

$$Z = Z_1 \cup Z_2,$$

where $Z_1$ has pure codimension $c$ on $X$, $Z_2$ has codimension $\geq c + 1$ on $X$ and we suppose that no irreducible components of $Z$ are contained in $Z_1$. Since $Z_1 \cap Z_2$ has codimension $\geq c + 2$ on $X$, the assertion in the cases (1)--(3) and a Mayer-Vietoris long exact sequence

$$\cdots \rightarrow H^{r+\epsilon}_{Z_1 \cap Z_2} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow \bigoplus_{j=1,2} H^{r+\epsilon}_{Z_j} (X, \mathfrak{T}_n(r)(X,D))$$

$$\rightarrow H^{r+\epsilon}_{Z} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow H^{r+\epsilon+1}_{Z_1 \cap Z_2} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow \cdots$$

imply isomorphisms

$$H^{r+\epsilon}_{Z} (X, \mathfrak{T}_n(r)(X,D)) \cong \bigoplus_{j=1,2} H^{r+\epsilon}_{Z_j} (X, \mathfrak{T}_n(r)(X,D)) \cong H^{r+\epsilon}_{Z_1} (X, \mathfrak{T}_n(r)(X,D)).$$

Similarly, we have $H^{r+\epsilon}_{Z \cap U} (U, \mathfrak{T}_n(r)(U)) \cong H^{r+\epsilon}_{Z_1 \cap U} (U, \mathfrak{T}_n(r)(U))$ by the purity of $\mathfrak{T}_n(r)(U)$ ([Sa2] Corollary 4.4.9). Hence we may assume that $Z$ has pure codimension $c$ on $X$. Moreover we may assume that no irreducible components of $Z$ are contained in $D$ by the cases (1)+(2) and a similar devissage argument. Then noting that $Z \cap D$ has codimension $\geq c + 1$ on $X$, we obtain the case (4) from the cases (1)+(2) and a long exact sequence

$$\cdots \rightarrow H^{r+\epsilon}_{Z \cap D} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow H^{r+\epsilon}_{Z} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow H^{r+\epsilon}_{Z \cap U} (U, \mathfrak{T}_n(r)(U))$$

$$\rightarrow H^{r+\epsilon+1}_{Z \cap D} (X, \mathfrak{T}_n(r)(X,D)) \rightarrow \cdots$$

This completes the proof of Theorem 6.5. $\square$

Definition 6.6 Let $X$ and $D$ be as in Theorem 6.5, and let $C$ be a cycle on $U := X - D$ of codimension $r$. Let $W \subset U$ be the support of $C$ and let $\overline{W}$ be its closure in $X$. Then we define the cycle class

$$\text{cl}_X(C) \in H^{2r}_{\overline{W}}(X, \mathfrak{T}_n(r)(X,D))$$

as the inverse image of $\text{cl}_U(C)$ ([Sa2] 5.1.2) under the isomorphism in Theorem 6.5

$$H^{2r}_{\overline{W}}(X, \mathfrak{T}_n(r)(X,D)) \xrightarrow{\sim} H^{2r}_{\overline{U}}(U, \mathfrak{T}_n(r)(U)).$$

Documenta Mathematica 18 (2013) 177–247
7 Cycle class map

Let $S, p$ and $X$ be as in Setting 3.1. In this section, we construct a cycle class morphism
\[
\cl_X : \Z(r)_X^\et \otimes_{\Z/p^n} \to \Sigma_n(r)_X \iso D(X_\et, \Z/p^n),
\]
(7.0.1)
following the method of Bloch [B3] § 4 (cf. [GL] § 3, see also Remark 7.3 below). Here $\Z(r)_X^\et$ denotes the étale sheafification on $X$ of the presheaf of cochain complexes
\[
U \mapsto z^r(U, \ast)[-2r],
\]
and $z^r(U, \ast)$ denotes Bloch’s cycle complex
\[
\cdots \longrightarrow z^r(U, q) \xrightarrow{d_q} z^r(U, q-1) \xrightarrow{d_{q-1}} \cdots \xrightarrow{d_1} z^r(U, 0).
\]

We review the definition of this complex briefly, which will be useful later. Let $\Delta^q$ be the standard cosimplicial scheme over $\Spec(\Z)$:
\[
\Delta^q := \Spec(\Z[t_0, t_1, \ldots, t_q] / (t_0 + t_1 + \cdots + t_q = 1)).
\]
A face of $\Delta^q$ (of codimension $a \geq 1$) is a closed subscheme defined by the equation
\[
t_{i_1} = t_{i_2} = \cdots = t_{i_a} = 0 \quad \text{for some} \quad 0 \leq i_1 < i_2 < \cdots < i_a \leq q.
\]
Now $z^r(U, q)$ is defined as the free abelian group generated by the set of all integral closed subschemes on $U \times \Delta^q$ of codimension $r$ which meet all faces of $U \times \Delta^q$ properly. Here a face of $U \times \Delta^q$ means the product of $U$ and a face of $\Delta^q$. Noting that the faces of codimension 1 are effective Cartier divisors, we define the differential map $d_q$ as the alternating sum of pull-back maps along the faces of codimension 1, which defines the above complex $z^r(U, \ast)$.

We fix a projective completion $\overline{\Delta^q}$ of $\Delta^q$ as follows:
\[
\overline{\Delta^q} := \Proj(\Z[T_0, T_1, \ldots, T_q, T_{\infty}] / (T_0 + T_1 + \cdots + T_q = T_{\infty})).
\]
Let $D^q \subset \overline{\Delta^q}$ be the hyperplane at infinity:
\[
D^q : T_{\infty} = 0.
\]

The following proposition plays a key role in our construction of the morphism (7.0.1).

**Proposition 7.1** Let $q$ and $r$ be integers with $q, r \geq 0$, and let $U$ be étale of finite type over $X$. Let $\Sigma^{r,q}$ be the set of all closed subsets on $U \times \Delta^q$ of pure codimension $r$ which meet all faces of $U \times \Delta^q$ properly. Here a face of $U \times \Delta^q$ means the product of $U$ and a face of $\Delta^q$. Noting that the faces of codimension 1 are effective Cartier divisors, we define the differential map $d_q$ as the alternating sum of pull-back maps along the faces of codimension 1, which defines the above complex $z^r(U, \ast)$.

We fix a projective completion $\overline{\Delta^q}$ of $\Delta^q$ as follows:
\[
\overline{\Delta^q} := \Proj(\Z[T_0, T_1, \ldots, T_q, T_{\infty}] / (T_0 + T_1 + \cdots + T_q = T_{\infty})).
\]
Let $D^q \subset \overline{\Delta^q}$ be the hyperplane at infinity:
\[
D^q : T_{\infty} = 0.
\]

The following proposition plays a key role in our construction of the morphism (7.0.1).

**Proposition 7.1** Let $q$ and $r$ be integers with $q, r \geq 0$, and let $U$ be étale of finite type over $X$. Let $\Sigma^{r,q}$ be the set of all closed subsets on $U \times \Delta^q$ of pure codimension $r$ which meet all faces of $U \times \Delta^q$ properly. For $W \in \Sigma^{r,q}$, let $\overline{W}$ be the closure of $W$ in $U \times \overline{\Delta^q}$. Then:

1. There is an isomorphism
\[
\cl^{r,q} : z^r(U, q) \otimes \Z/p^n \iso \lim_{W \in \Sigma^{r,q}} H^{2r}_{\overline{\Delta^q}}(U \times \overline{\Delta^q}, \Sigma_n(r)(U \times \overline{\Delta^q} \setminus D^q))
\]
sending a cycle $C \in z^r(U, q)$ to the cycle class $\cl_{U \times \overline{\Delta^q}}(C)$ (see Definition 6.6).
(2) For \( W \in \Sigma^{r,q} \), the natural morphism

\[
\tau \leq 2r \ R\Gamma_{\mathcal{W}} \left( U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q, U \times D^q} \right) \\
\longrightarrow H^{2r}_{U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q, U \times D^q}} \left( U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q, U \times D^q} \right) \left[ -2r \right]
\]

is an isomorphism in the derived category of \( \mathbb{Z}/p^n \)-modules.

(3) Let \( C \) be a cycle which belongs to \( z'(U, q) \), and let \( W \) be the support of \( C \) (note that \( W \) belongs to \( \Sigma^{r,q} \)). Let \( \overline{i} : U \times \Delta^q \hookrightarrow U \times \Delta^q \) be the closure of a face map \( i : U \times \Delta^{q-1} \hookrightarrow U \times \Delta^q \). Then the pull-back map

\[
\overline{i}^* : H^{2r}_{U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q, U \times D^q}} \left( U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q, U \times D^q} \right) \\
\longrightarrow H^{2r}_{U \times \Delta^{q-1}, \mathcal{I}(r)_{U \times \Delta^{q-1}, U \times D^{q-1}}} \left( U \times \Delta^{q-1}, \mathcal{I}(r)_{U \times \Delta^{q-1}, U \times D^{q-1}} \right)
\]

sends the cycle class \( \text{cl}_{U \times \Delta^q}(C) \) to \( \text{cl}_{U \times \Delta^{q-1}}(i^* C) \), where \( i^* C \) denotes the pull-back of the cycle \( C \) along \( i \).

Proof. (1) and (2) follow from Theorem 6.5 and the definition of \( z'(U, q) \). We show (3). By Theorem 6.5, it is enough to show that the pull-back map

\[
i^* : H^{2r}_{U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q}} \left( U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q} \right) \\
\longrightarrow H^{2r}_{U \times \Delta^{q-1}, \mathcal{I}(r)_{U \times \Delta^{q-1}}} \left( U \times \Delta^{q-1}, \mathcal{I}(r)_{U \times \Delta^{q-1}} \right)
\]

sends the cycle class \( \text{cl}_{U \times \Delta^q}(C) \) to \( \text{cl}_{U \times \Delta^{q-1}}(i^* C) \). Put

\[
\mathcal{U} := U \times \Delta^q, \quad \mathcal{D} := i(U \times \Delta^{q-1}) \subset \mathcal{U} \quad \text{and} \quad \mathcal{Y} := \mathcal{U} - \mathcal{D}
\]

and let \( t \in \Gamma(\mathcal{U}, \mathcal{O}_\mathcal{U}) \) be a defining equation of \( \mathcal{D} \). Noting that \( i^{-1}(W) = W \cap \mathcal{D} \), consider the following diagram:

\[
\begin{array}{ccc}
H^{2r}_{U \times \Delta^q, \mathcal{I}(r)_{U \times \Delta^q}}(\mathcal{Y}, \mathcal{I}(r)_{U \times \Delta^q}) & \overset{i^*}{\longrightarrow} & H^{2r}_{U \times \Delta^{q-1}, \mathcal{I}(r)_{U \times \Delta^{q-1}}}(\mathcal{Y}, \mathcal{I}(r)_{U \times \Delta^{q-1}}) \\
\downarrow \alpha & & \downarrow i_* \\
H^{2r+1}_{U \times \Delta^q}(\mathcal{Y}, \mathcal{I}(r+1)_{U \times \Delta^q}) & \overset{-\delta}{\longrightarrow} & H^{2r+2}_{U \times \Delta^q}(\mathcal{Y}, \mathcal{I}(r+1)_{U \times \Delta^q}) \\
\bigoplus_{y \in W^o} H^{2r+1}_{U \times \Delta^q}(\mathcal{Y}, \mathcal{I}(r+1)_{U \times \Delta^q}) & \overset{-\delta}{\longrightarrow} & \bigoplus_{x \in (W \cap \mathcal{D})^o} H^{2r+2}_{U \times \Delta^q}(\mathcal{Y}, \mathcal{I}(r+1)_{U \times \Delta^q}) \\
\bigoplus_{y \in W^o} \kappa(y)^{x/p^n} & \overset{\text{div}}{\longrightarrow} & \bigoplus_{x \in (W \cap \mathcal{D})^o} \mathbb{Z}/p^n.
\end{array}
\]

Here we defined \( \alpha \) by sending \( \omega \in H^{2r}_{U \times \Delta^q}(\mathcal{Y}, \mathcal{I}(r)_{U \times \Delta^q}) \) to \( \{ t \} \cup \omega \mid \mathcal{Y} \), where \( \{ t \} \mid \mathcal{Y} \) denotes the class of \( t \mid \mathcal{Y} \in \Gamma(\mathcal{Y}, \mathcal{O}_\mathcal{Y}) \) in \( H^1(\mathcal{Y}, \mathcal{I}(1)_{\mathcal{Y}}) \). The arrows \( i_* \), \( g \) and \( g' \) are
Gysin isomorphisms (cf. [Sa2] Theorem 4.4.7). The arrows $\delta$ are boundary maps of localization long exact sequences, and the central square commutes obviously. The arrow $\delta$ denotes the divisor map, and the bottom square commutes by the compatibility in loc. cit. Theorem 6.1.1 and [JSS] Theorem 3.1.1 (see also Remark 3.7 of this paper). The top square commutes by the following equalities ($\omega \in H_W^0(\mathcal{Y}, \mathcal{T}_n(r))$):

$$i_* \circ i^*(\omega) = c_{\mathcal{Y}}(\mathcal{D}) \cup \omega = -\delta(t \cdot \mathcal{Y}) \cup \omega = -\delta(t \cdot \mathcal{Y} \cup \omega) = -\delta \circ \alpha(\omega),$$

where the first (resp. second) equality follows from the projection formula in [Sa2] Corollary 7.2.4 (resp. the same compatibility as mentioned before). Hence the assertion follows from the transitivity of Gysin maps for $W \cap \mathcal{D} \hookrightarrow \mathcal{D} \hookrightarrow \mathcal{Y}$ (loc. cit. Corollary 6.3.3) and the fact that the divisor map $\text{div}$ sends $t|_y \in \kappa(y)^*/p^n$ to the cycle $i^*[y]$, where $[y]$ means the cycle on $\mathcal{Y}$ given by the closure of $y$. This completes the proof. □

We construct the morphism (7.0.1). For $U$ as in the proposition, there is a diagram of cochain complexes concerning $\bullet$ (see Corollary 3.9 (2) for $G_n(r)\bullet$):

$$z^*(U, q) \otimes \mathbb{Z}/p^n[-2r] \xrightarrow{d^r \downarrow} \lim_{W \in \Sigma^r q} H_W^2(U \times \Delta^r, \mathcal{T}_n(r)(U \times \Delta^r, U \times D^n))[-2r]$$

$$\xleftarrow{\alpha^r \downarrow} \lim_{W \in \Sigma^r q} \tau_{\leq 2r}^{-1} \Gamma(W \times \Delta^r, G_n(r)^\bullet(U \times \Delta^r, U \times D^n))$$

$$\xrightarrow{\beta^r \downarrow} \Gamma(U \times \Delta^r, G_n(r)^\bullet(U \times \Delta^r, U \times D^n)).$$

Here $\alpha^r \downarrow$ and $\beta^r \downarrow$ are natural maps of complexes, which are obviously contravariant for the face maps $U \times \Delta^{r-1} \hookrightarrow U \times \Delta^r$. The map $e^r \downarrow$ is bijective and contravariant for these face maps by Proposition 7.1 (1) and (3). Hence we get homomorphisms of double complexes concerning $(\bullet, \bullet)$:

$$z^*(U, \bullet) \otimes \mathbb{Z}/p^n[-2r] \xrightarrow{(d^r \downarrow)^{-1} \circ \alpha^r \downarrow} \lim_{W \in \Sigma^r \bullet} \tau_{\leq 2r}^{-1} \Gamma(W \times \Delta^r, G_n(r)^\bullet(U \times \Delta^r, U \times D^n))$$

$$\xrightarrow{\beta^r \downarrow} \Gamma(U \times \Delta^r, G_n(r)^\bullet(U \times \Delta^r, U \times D^n))$$

$$\xleftarrow{} \Gamma(U, G_n(r)_U),$$

where the differentials in the $\bullet$-direction are alternating sums of pull-back maps along the faces of codimension 1, and the last arrow is the inclusion to the factor of $\bullet = 0$. The first and the last arrows are quasi-isomorphisms on the associated total complexes by Proposition 7.1 (2) and Corollary 4.3, respectively. We thus obtain the desired morphism (7.0.1) in $D(X_{et}, \mathbb{Z}/p^n)$ by sheafifying the diagram of total complexes.

Remark 7.2 The Rost-Voevodsky theorem ([Vo1], [Vo2], [We], cf. [BK1] §3) and the Suslin-Voevodsky theorem [SV] (cf. [GL]) imply that the morphism (7.0.1) induces isomorphisms (cf. [Sa2] Conjecture 1.4.1):

$$\tau_{\leq r}(\mathbb{Z}(r)_X^t \otimes \mathbb{Z}/p^n) \xrightarrow{\sim} \mathcal{T}_n(r)_X \quad \text{in} \ D^b(X_{et}, \mathbb{Z}/p^n),$$

$$\tau_{\leq r}(\mathbb{Z}(r)_X^{2r} \otimes \mathbb{Z}/p^n) \xrightarrow{\sim} \tau_{\leq r} R\varepsilon_* \mathcal{T}_n(r)_X \quad \text{in} \ D^b(\mathcal{Z}_{zar}, \mathbb{Z}/p^n),$$

$$\tau_{\leq r}(\mathbb{Z}(r)_X^{3r} \otimes \mathbb{Z}/p^n) \xrightarrow{\sim} \tau_{\leq r} R\varepsilon_* \mathcal{T}_n(r)_X \quad \text{in} \ D^b(\mathcal{Z}_{zar}, \mathbb{Z}/p^n),$$

$$\tau_{\leq r}(\mathbb{Z}(r)_X^{4r} \otimes \mathbb{Z}/p^n) \xrightarrow{\sim} \tau_{\leq r} R\varepsilon_* \mathcal{T}_n(r)_X \quad \text{in} \ D^b(\mathcal{Z}_{zar}, \mathbb{Z}/p^n).$$
which one can easily check by similar arguments as in [SS] §A.2. Here $\mathcal{Z}(r)^{\text{zar}}_X$ denotes the complex of Zariski sheaves on $X$ defined as $U \mapsto z^r(U, \ast)[-2r]$, and $\varepsilon$ denotes the continuous map of sites $X_{\text{et}} \to X_{\text{zar}}$.

**Remark 7.3** If $X$ is smooth over $S$, then $\mathcal{Z}(r)^{\text{zar}}_X$ is concentrated in degrees $\leq r$ by a result of Geisser [Ge] Corollary 4.4. Hence his arguments in loc. cit. §6, Proof of Theorem 1.3 gives an alternative construction of (7.0.1) in this case.

8 de Rham-Witt cohomology and homology

In this section we define two kinds of de Rham-Witt complexes for normal crossing varieties playing the roles of cohomology and homology, and relate them with the modified de Rham-Witt complex of Hyodo [Hy2]. The main results of this section are Theorems 8.8 and 8.12 below.

Let $k$ be a field of characteristic $p > 0$, and let $Y$ be a normal crossing variety over $k$. Let $U \subset Y$ be a dense open subset which is smooth over $k$, and let $\sigma : U \hookrightarrow Y$ be the natural open immersion.

**Definition 8.1** We define the complex $(W_n A^\bullet_Y, d)$ of étale sheaves on $Y$ as the differential graded subalgebra of $\sigma^\ast W_n \Omega^\bullet_U$ generated by

$$W_n \theta_Y \quad \text{and} \quad \lambda^1_{n,\sigma} (\subset \sigma^\ast W_n \Omega^1_U),$$

which we call the cohomological de Rham-Witt complex of $Y$. It is easy to see that $W_n A^\bullet_Y$ does not depend on the choice of $U$. For $n = 1$, $W_1 A^\bullet_Y$ is the same as the complex $A^\bullet_Y$ defined in [Sa1] §3.3.

By the relations

$$\begin{align*}
V(aR(x)) &= V(a)x \quad (a \in W_n \theta_U, x \in W_{n+1} \Omega^{\text{log}}_U) \\
F(ax) &= F(a)R(x) \quad (a \in W_{n+1} \theta_U, x \in W_{n+1} \Omega^{\text{log}}_U) \\
R(ax) &= R(a)R(x) \quad (a \in W_{n+1} \theta_U, x \in W_{n+1} \Omega^{\text{log}}_U)
\end{align*}$$

(cf. [I1] I Théorème 2.17, Proposition 2.18), the operators $V, F, R$ on $W_n \Omega^\bullet_U$ induce operators

$$\begin{align*}
V : W_n A_Y^1 &\longrightarrow W_{n+1} A_Y^1, \\
F : W_{n+1} A_Y^1 &\longrightarrow W_n A_Y^1, \\
R : W_{n+1} A_Y^1 &\longrightarrow W_n A_Y^1,
\end{align*}$$

which satisfy relations

$$\begin{align*}
VF &= VF = p, \quad FdV = d, \quad dF = pFd, \quad Vd = pdV, \\
RV &= VR, \quad RF = FR, \quad Rd = dR.
\end{align*}$$

The local structure of $W_n A^1_Y$ can be written in terms of the usual Hodge-Witt sheaves of the strata of $Y$. 

**Documenta Mathematica** 18 (2013) 177–247
Proposition 8.2  
(1) Assume that \( Y \) is simple, and let \( Y_1, Y_2, \ldots, Y_q \) be the irreducible components of \( Y \). Then there is an exact sequence on \( Y_{\text{et}} \):

\[
0 \rightarrow W^n A_Y^r \xrightarrow{\sigma^r} \bigoplus_{|I|=1} W^n \Omega^r_{\overline{Y}} \xrightarrow{\theta^1} \bigoplus_{|I|=2} W^n \Omega^r_{Y_I} \xrightarrow{\theta^2} \cdots \xrightarrow{\theta^{q-1}} \bigoplus_{|I|=q} W^n \Omega^r_{Y_I} \rightarrow 0,
\]

where the notation is the same as in Proposition 2.2.

(2) Assume that \( Y \) is embedded into a smooth \( k \)-variety \( \mathcal{Y} \) as a normal crossing divisor. Let \( i : Y \hookrightarrow \mathcal{Y} \) be the closed immersion. Then there is a short exact sequence on \( Y_{\text{et}} \):

\[
0 \rightarrow W^n \Omega^r_{\mathcal{Y}}(\log Y) \rightarrow W^n \Omega^r_{\mathcal{Y}} \rightarrow i_* W^n A_Y^r \rightarrow 0.
\]

Proof. (1) follows from the contravariant functoriality of Hodge-Witt sheaves of smooth varieties and the same arguments as for [Sa1] Proposition 3.2.1. The assertion (2) follows from (1) and [Mo] Lemma 3.15.1.

We next introduce homological Hodge-Witt sheaves.

Definition 8.3 For \( r \geq 0 \), we define the étale sheaf \( W^n \Xi^r_Y \) on \( Y \) as the \( W^n \mathcal{O}_Y \)-submodule of \( \sigma_* W^n \Omega^r_U \) generated by \( \nu^r_{Y,n} \). Similarly as for \( W^n \Lambda^r_Y \), the sheaf \( W^n \Xi^r_Y \) does not depend on the choice of \( U \). For \( n = 1 \), \( W^1 \Xi^r_Y \) agrees with the sheaf \( \Xi^r_Y \) defined in [Sa1] §2.5.

Since \( \lambda^r_{Y,n} \subset \nu^r_{Y,n} \) by definition, we have \( W^n A^r_Y \subset W^n \Xi^r_Y \), which agree with \( W^n \Omega^r_Y \) when \( Y \) is smooth (cf. [Sa1] Remark 3.1.4). The following local description will be useful later.

Proposition 8.4  
(1) Under the same setting and notation as in Proposition 8.2 (1), there is a canonical ascending filtration \( F_\alpha (\alpha \geq 0) \) on \( W^n \Xi^r_Y \) satisfying

\[
F_0(W^n \Xi^r_Y) = 0 \quad \text{and} \quad \bigoplus_{|I|=\alpha} W^n \Omega^r_{Y_I} \simeq G^r_{\alpha} W^n \Xi^r_Y,
\]

where the isomorphism for \( \alpha \geq 2 \) depends on the fixed ordering of the irreducible components of \( Y \).

(2) Under the same setting and notation as in Proposition 8.2 (2), there is a short exact sequence on \( Y_{\text{et}} \):

\[
0 \rightarrow W^n \Omega^r+1_{\mathcal{Y}} \rightarrow W^n \Omega^r+1_{\mathcal{Y}}(\log Y) \xrightarrow{\theta_0} i_* W^n \Xi^r_Y \rightarrow 0,
\]

where \( \theta_0 \) is induced by the Poincaré residue mapping

\[
\theta_0 : W^n \Omega^r+1_{\mathcal{Y}}(\log Y) \rightarrow (i\sigma)_* W^n \Omega^r_U.
\]
Proof. We first recall the following fact due to Mokrane [Mo] Proposition 1.4.5. Under the setting of (2), let $F_a W_n^r \Omega_{Y,log}^m (\log Y) (a \geq 0)$ be the image of the product

$$W_n^r \Omega_{Y,log}^m (\log Y) \times W_n^r \Omega_{Y,log}^{m-a} \longrightarrow W_n^r \Omega_{Y,log}^m (\log Y).$$

Put $F_{-1} W_n^r \Omega_{Y,log}^m (\log Y) := 0$. Then there are isomorphisms

$$\text{gr}_a^F W_n^r \Omega_{Y,log}^m (\log Y) \simeq \begin{cases} W_n^r \Omega_{Y,log}^m & (a = 0) \\ \bigoplus_{|I|=a} W_n^r \Omega_{Y,log}^{m-a} & (a \geq 1) \end{cases} \quad (8.4.1)$$

which are induced by Poincaré residue mappings for $a \geq 1$ and depend on the fixed ordering of the irreducible components of $Y$. We prove (2). Because the complement $\Sigma := Y - U$ has codimension $\geq 2$ on $\mathfrak{M}$ and the sheaves $W_n^r \Omega_{Y,log}^{m+1}$ and $W_n^r \Omega_{Y,log}^{m+1} (\log Y)$ are finitely successive extensions of locally free $\mathcal{O}_U$-modules of finite rank ([III] I Corollaire 3.9), the sequence

$$0 \longrightarrow W_n^r \Omega_{Y,log}^{m+1} \longrightarrow W_n^r \Omega_{Y,log}^{m+1} (\log Y) \overset{d_0}{\longrightarrow} (i \sigma)_* W_n^r \Omega_{Y,log}^m$$

is exact by (8.4.1) for $\mathfrak{M} - \Sigma$. Hence it is enough to show that $\text{Im}(d_0) = i_* W_n^r \Xi_Y^r$. Let $F_a (\nu_{Y,r,n}^r) (a \geq 0)$ be the filtration on $\nu_{Y,r,n}^r$ in [Sa1] Proposition 2.2.1, which is defined under the assumption that $Y$ is simple and satisfies

$$F_0 (\nu_{Y,r,n}^r) = 0 \quad \text{and} \quad \text{gr}_a^F \nu_{Y,r,n}^r \simeq \bigoplus_{|I|=a} W_n^r \Omega_{Y,log}^{r-a+1} \quad \text{(non-canonically)}. \quad (8.4.2)$$

Hence comparing this local description of $\nu_{Y,r,n}^r$ with (8.4.1) for $m = r + 1$, we see that $\text{Im}(d_0) = i_* W_n^r \Xi_Y^r$. As for (1), we define the desired filtration $F_a (W_n^r \Xi_Y^r)$ as the $W_n^r \mathcal{O}_Y$-submodule generated by $F_a (\nu_{Y,r,n}^r)$. This filtration satisfies the required properties by (2) and again by (8.4.1).

Since the residue mapping $g_0$ in Proposition 8.4 (2) commutes with the operators $d, V, F, R$ (cf. (8.1.1)), these operators on $W_n^r \Omega_{Y,log}^m$ induce operators

$$\begin{align*}
  d &: W_n^r \Xi_Y^r \longrightarrow W_n^r \Xi_Y^{r+1}, \\
  V &: W_n^r \Xi_Y^r \longrightarrow W_{n+1}^r \Xi_Y^r, \\
  F &: W_{n+1}^r \Xi_Y^r \longrightarrow W_n^r \Xi_Y^r, \\
  R &: W_{n+1}^r \Xi_Y^r \longrightarrow W_n^r \Xi_Y^r
\end{align*}$$

by Proposition 8.4 (2) (without the assumptions in Proposition 8.4 (1) or (2)), which satisfy the relations listed in (8.1.2) and (8.1.3). We call the resulting complex $(W_n^r \Xi_Y^r, d)$ the homological de Rham-Witt complex of $Y$.

Remark 8.5 There are natural injective homomorphisms of complexes

$$\bigoplus_{r=0}^{\dim(Y)} \lambda_{Y,n}^r [-r] \hookrightarrow W_n^r A_Y^r, \quad \bigoplus_{r=0}^{\dim(Y)} \nu_{Y,n}^r [-r] \hookrightarrow W_n^r \Xi_Y^r,$$

where the differentials on the complexes on the left hand side are defined as zero. Indeed the differentials on $W_n^r \Omega_{Y,log}^m$ are zero on $W_n^r \Omega_{Y,log}^m$.

Documenta Mathematica 18 (2013) 177–247
The following Proposition 8.6 and Theorem 8.8 explain a fundamental relationship between $W_n^\bullet_A Y$ and $W_n^\bullet\Xi Y$.

**Proposition 8.6** The complex $W_n^\bullet\Xi Y$ is a $W_n^\bullet_A Y$-module, that is, there is a natural $W_n^\bullet_O Y$-bilinear pairing
\[ W_n^\bullet_A Y \times W_n^\bullet\Xi Y \to W_n^\bullet\Xi Y^{r+s} \quad (r, s \geq 0) \] (8.6.1)
satisfying the Leibniz rule
\[ d(x \cdot y) = (dx) \cdot y + (-1)^r x \cdot dy \quad (x \in W_n^\bullet A Y, \ y \in W_n^\bullet\Xi Y). \]
Moreover this pairing is compatible with $R$ and satisfies relations
\[ F(x \cdot y) = F(x) \cdot F(y) \]
\[ x \cdot V(y) = V(F(x) \cdot y) \]
\[ V(x) \cdot y = V(x \cdot F(y)) \]
\[ (x \in W_n^\bullet A Y, \ y \in W_n^\bullet\Xi Y). \]

**Proof.** The pairing (8.6.1) is induced by the product of $W_n^\bullet \Omega_U^\bullet$ and the biadditive pairing $\lambda^{r+s}_{Y,n} \to \nu^{r+s}_{Y,n}$ defined in [Sa1] Definition 3.1.1. The properties of the pairing (8.6.1) follow from the corresponding properties of the product of $W_n^\bullet \Omega_U^\bullet$ ([I1] I Théorème 2.17, Proposition 2.18).

**Remark 8.7** When $k$ is perfect and $Y$ is the special fiber of a regular semistable family $X$ over a discrete valuation ring with residue field $k$, we have
\[ W_n^\bullet A Y \subset W_n^\bullet \omega^\bullet Y \subset W_n^\bullet \Xi Y \]
by [Sa1] Proposition 4.2.1. Here $W_n^\bullet \omega^\bullet Y$ denotes the modified de Rham-Witt complex associated with $X$ [Hy2]. The complex $W_n^\bullet \Xi Y$ does not in general have a product structure unless $Y$ is smooth.

**Theorem 8.8** Assume that $k$ is perfect and that $Y$ is proper over $k$. Put $b := \dim(Y)$ and $W_n := W_n(k)$. Then:

1. There is a canonical trace map $\text{tr}_n : H^{2b}(Y, W_n^\bullet \Xi Y) \to W_n$, which is bijective if $Y$ is geometrically connected over $k$.

2. The pairing
\[ H^i(Y, W_n^\bullet A Y) \times H^{2b-i}(Y, W_n^\bullet \Xi Y) \to H^{2b}(Y, W_n^\bullet \Xi Y) \xrightarrow{\text{tr}_n} W_n \]
is a non-degenerate pairing of finitely generated $W_n$-modules for any $i \geq 0$.  

*Documenta Mathematica* 18 (2013) 177–247
Proof. (1) Let $f_n$ be the canonical morphism $W_n Y \to W_n$, where $W_n Y$ means the scheme consisting of the topological space $Y$ and the structure sheaf $W_n \mathcal{O}_Y$. Since $H^b(Y, W_n \Xi^\bullet_Y) \simeq H^b(Y, W_n \Xi^\bullet_Y)$, our task is to show that

$$W_n \Xi^\bullet_Y \xrightarrow{f_n} f_n^! W_n$$

in $D_{qc}(W_n Y, W_n \mathcal{O}_Y)$, (8.8.1)

where the subscript $qc$ means the triangulated subcategory consisting of complexes with quasi-coherent cohomology sheaves and $f_n^!$ means the twisted inverse image functor of Hartshorne [Ha]. If $Y$ is smooth, (8.8.1) is a theorem of Ekedahl [E]. In the general case, (8.8.1) is reduced to the smooth case by Proposition 8.4 (2) and the same arguments as for [Sa1] Proposition 2.5.9.

(2) The case $n = 1$ follows from [Sa1] Corollary 2.5.11, Proposition 3.3.5. The case $n \geq 2$ follows from a standard induction argument on $n$ and the following lemma: □

Lemma 8.9  (1) There are injective homomorphisms

$$p : W_{n-1} \Lambda_Y^\bullet \xhookrightarrow{} W_n \Lambda_Y^\bullet$$

and

$$\bar{p} : W_{n-1} \Xi_Y^\bullet \xhookrightarrow{} W_n \Xi_Y^\bullet$$

induced by the multiplication by $p$ on $W_n \Lambda_Y^\bullet$ and $W_n \Xi_Y^\bullet$, respectively.

(2) The following natural projections of complexes are quasi-isomorphisms:

$$W_n \Lambda_Y^\bullet / \bar{p}(W_{n-1} \Lambda_Y^\bullet) \longrightarrow \Lambda_Y^\bullet$$

and

$$W_n \Xi_Y^\bullet / \bar{p}(W_{n-1} \Xi_Y^\bullet) \longrightarrow \Xi_Y^\bullet.$$

Proof. When $Y$ is smooth, the assertions are due to Illusie [I1] Proposition 3.4 and Corollaire 3.15. In the general case, (1) follows from that for the dense open subset $U \subset Y$ we fixed before. To prove (2), we may assume that $Y$ is simple. Then the assertions follow from those for the strata of $Y$ and Propositions 8.2 (1) and 8.4 (1). □

In the rest of this section, we work under the following setting. Let $A$ be a discrete valuation ring with perfect residue field $k$, and let $X$ be a regular semistable family over $A$. Put $Y := X \otimes_A k$. Recall that

$$W_n \Lambda_Y^\bullet \subset W_n \omega_Y^\bullet \subset W_n \Xi_Y^\bullet$$

by Remark 8.7. We define a Frobenius endomorphism $\varphi$ on these complexes by $p^m F$ on degree $m \geq 0$. There is a short exact sequence of complexes with Frobenius action

$$0 \longrightarrow W_n \omega_Y^\bullet (-1)[-1] \xrightarrow{\varphi} W_n \omega_Y^\bullet \longrightarrow W_n \omega_Y^\bullet \longrightarrow 0$$

(8.9.1)

by [Hy2] (1.4.3), where the complex $W_n \omega_Y^\bullet (-1)$ means the complex $W_n \omega_Y^\bullet$ with Frobenius endomorphism $p \cdot \varphi$. The monodromy operator

$$N : W_n \omega_Y^\bullet \longrightarrow W_n \omega_Y^\bullet (-1)$$

is defined as the connecting morphism associated with this sequence.
Proposition 8.10 There is a short exact sequence of complexes with Frobenius action

\[
0 \rightarrow W_n A_Y^\bullet \rightarrow W_n \Omega_Y^r \rightarrow W_n \Xi_Y^r (-1)[-1] \rightarrow 0
\]  
(8.10.1)

fitting into a commutative diagram of complexes

\[
\begin{array}{cccc}
W_n \omega^r_Y (-1)[-1] \\
\downarrow \downarrow \downarrow \\
W_n A_Y^\bullet & \rightarrow & W_n \Omega_Y^r & \rightarrow & W_n \Xi_Y^r (-1)[-1] \\
\downarrow & & \downarrow & & \downarrow \\
W_n \omega^r_Y \\
\end{array}
\]

Consequently, we obtain a complex of \(W_n(k)\)-modules with Frobenius action for \(i \geq 0\)

\[
H^i(Y, W_n A_Y^\bullet) \rightarrow H^i(Y, W_n \omega_Y^r) \rightarrow H^i(Y, W_n \Xi_Y^r(-1)[-1]) \rightarrow H^i(Y, W_n \Omega_Y^r(-1). \)  
(8.10.2)

Proof. Let \(\sigma : U \rightarrow Y\) be as before and define a homomorphism \(\partial : W_n \tilde{\omega}_Y \rightarrow \sigma_* W_n \Omega_Y^r(-1)\) as the composite

\[
\partial : W_n \tilde{\omega}_Y \rightarrow \sigma_* \sigma^* W_n \tilde{\omega}_Y \rightarrow \sigma_* (W_n \Omega_Y^r \oplus W_n \Omega_Y^{r-1}) \cong \sigma_* W_n \Omega_Y^{r-1},
\]

where the second arrow is obtained from the fact that the sequence (8.9.1) splits on \(U\).

It is easy to see that \(\partial\) satisfies

\[
d\partial = \partial d \quad \text{and} \quad \partial F = pF\partial,
\]

which induces a map of complexes \(\partial^* : W_n \tilde{\omega}_Y \rightarrow \sigma_* W_n \Omega_Y^r(-1)[-1]\). To show that \(\partial^*\) induces the exact sequence (8.10.1), we may assume the assumption in Proposition 8.2 (2). Then we have an isomorphism of complexes

\[
W_n \omega^r_Y \cong W_n \Omega^r_Y (\log Y)/W_n \Omega^r_Y (-\log Y) \quad \text{([Hy2] p. 247 Lemma)}
\]

and the assertion follows from Propositions 8.2 (2) and 8.4 (2). The commutativity of the diagram in the proposition is straightforward and left to the reader. \(\square\)

We prove that the monodromy-weight conjecture for log crystalline cohomology implies an invariant cycle 'theorem' (cf. [I2] 2.4.5), which will be useful in §§9–10 below. Let \(A\) be a discrete valuation ring with finite residue field \(k\), and \(X\) be a regular scheme which is projective flat over \(A\) with strict semistable reduction. Put \(K_0 := \text{Frac}(W(k))\) and \(Y := X \otimes_A k\). For integer \(i \geq 0\), we define

\[
C^i := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{\longrightarrow n \geq 1} H^i(Y, W_n A_Y^\bullet),
\]

(8.10.3)

\[
D^i := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{\longrightarrow n \geq 1} H^i(Y, W_n \omega_Y^r),
\]

(8.10.4)

\[
E^i := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{\longrightarrow n \geq 1} H^i(Y, W_n \Xi_Y^r),
\]

(8.10.5)
which are finite-dimensional over $K_0$ and $F$-isocrystals over $\text{Spec}(k)$. The content of the monodromy-weight conjecture due to Mokrane is the following:

**Conjecture 8.11** ([Mo] Conjecture 3.27) The filtration on $D^i$ induced by the weight spectral sequence (loc. cit. 3.25, cf. [Na] (2.0.9; p)) agrees with the monodromy filtration induced by the monodromy operator $N : D^i \to D^i(-1)$ ([Mo] 3.26).

**Theorem 8.12** Let $i \geq 0$ be an integer, and assume Conjecture 8.11 for $D^i$. Then the following sequence of $F$-isocrystals over $\text{Spec}(k)$ induced by (8.10.2) is exact:

$$C^i \xrightarrow{N} D^i \xrightarrow{N} D^i(-1) \xrightarrow{\partial} E^i(-1).$$

**Proof.** Suppose that $\#(k) = p^a$. Then $\varphi^a$ is $K_0$-linear and we use the notion of weights concerning $\varphi^a$. Because the groups

$$\mathbb{H}^i(Y, W_n A_Y^\ast), \quad \mathbb{H}^i(Y, W_n \omega_Y^\ast), \quad \mathbb{H}^i(Y, W_n \Xi_Y^\ast), \quad \mathbb{H}^i(Y, W_n \varpi_Y^\ast)$$

are finite for any $n \geq 1$, there is a diagram of $F$-isocrystals with exact rows by (8.9.1) and Proposition 8.10

$$C^n \xrightarrow{\partial} D^i \xrightarrow{\partial} E^i(-1) \xrightarrow{\partial} C^{i+1} \xrightarrow{\partial} D^i(-1) \xrightarrow{\partial} E^i(-1),$$

where we put

$$\tilde{D}^i := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} \mathbb{H}^i(Y, W_n \varpi_Y^\ast).$$

By the assumption on $D^i$, $\text{Ker}(N)$ has weights $\leq i$ and $\text{Coker}(N)$ has weights $\geq i + 2$. Hence for the reason of weights, it is enough to show the following lemma, where we do not need Conjecture 8.11:

**Lemma 8.13** For integers $i \geq 0$, $C^i$ has weights $\leq i$ and $E^i$ has weights $\geq i$.

**Proof of Lemma 8.13.** When $Y$ is smooth, the lemma is a consequence of the Katz-Messing theorem [KM]. In the general case, $C^i$ has weights $\leq i$ by the spectral sequence of $F$-isocrystals obtained from Proposition 8.2 (1)

$$E_1^{s,t} = \bigoplus_{|I| = s + 1} D_I^t \implies C^{s+t},$$

where we put

$$D_I^t := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} \mathbb{H}^t(Y_I, W_n \Omega_{Y_I}^\ast).$$

Moreover $E^i$ has weights $\geq i$ by the duality result in Theorem 8.8. Thus we obtain Lemma 8.13 and Theorem 8.12. 

□
Remark 8.14 One can show Lemma 8.13 for $E^1$ alternatively by the Katz-Messing theorem and the spectral sequence obtained from Proposition 8.4(1)

$$E_1^{a,t} = \bigoplus_{|I|=1-s} D_{I,s}^{2a+1}(s) \Rightarrow E^{a,t}.$$ 

9 Comparison with the finite part of Bloch-Kato

In this section we relate the cohomology of $p$-adic étale Tate twists with the finite part of Bloch-Kato [BK2]. Let $p$ be a prime number, and let $K$ be a $p$-adic local field, i.e., a finite extension of $\mathbb{Q}_p$. Let $O_K$ be the integer ring of $K$, and let $k$ be the residue field of $O_K$. In this section we consider Tate twists only in the sense of $G_K$-modules (and not in the sense of $F$-crystals). For a topological $G_K$-module $M$ and an integer $r \in \mathbb{Z}$, we define

$$M(r) := \begin{cases} M \otimes_{\mathbb{Z}_p} \mathbb{Z}_p(1)^{\otimes r} & (r \geq 0), \\ \text{Hom}_{\mathbb{Z}_p}(\mathbb{Z}_p(1)^{\otimes (-r)}, M) & (r < 0), \end{cases}$$

where $\mathbb{Z}_p(1)$ denotes the topological $G_K$-module $\lim_{n \geq 1} \mu_{p^n}(\overline{K})$.

Let $X$ be a regular scheme which is projective flat over $O_K$ with strict semistable reduction, and put $X_K := X \otimes_{O_K} K$ and $Y := X \otimes_{O_K} k$. Let $j : X_K \hookrightarrow X$ be the natural open immersion, and let $i$ and $r$ be non-negative integers. Put $\mathcal{V}^i := H^i(X_K, \mathbb{Q}_p)$ (see also Notation) and

$$H^{i+1}(X, T_{\mathbb{Q}_p}(r)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^{i+1}(X, T_n(r)),$$

which are finite-dimensional over $\mathbb{Q}_p$. Let $F^\bullet$ be the filtration on $H^{i+1}(X_K, \mathbb{Q}_p(r))$ resulting from the Hochschild-Serre spectral sequence

$$E_2^{a,b} = H^a(K, \mathcal{V}^b(r)) \Rightarrow H^{a+b}(X_K, \mathbb{Q}_p(r)). \quad (9.0.1)$$

Let $F^q H^{i+1}(X, T_{\mathbb{Q}_p}(r))$ be the inverse image of $F^q H^{i+1}(X_K, \mathbb{Q}_p(r))$ under the canonical map $j^* : H^{i+1}(X, T_{\mathbb{Q}_p}(r)) \to H^{i+1}(X_K, \mathbb{Q}_p(r))$. We have

$$\Phi^{i,r} := \text{gr}_{F^r} H^{i+1}(X, T_{\mathbb{Q}_p}(r)) \subset \text{gr}_{F^r} H^{i+1}(X_K, \mathbb{Q}_p(r)) = H^1(K, \mathcal{V}^i(r))$$

by definition. We relate $\Phi^{i,r}$ with the finite part of Bloch-Kato [BK2]:

$$H^1_f(K, \mathcal{V}^i(r)) := \text{Ker}(\epsilon : H^1(K, \mathcal{V}^i(r)) \to H^1(K, \mathcal{V}^i \otimes_{\mathbb{Q}_p} B_{\text{cryst}})).$$

where $B_{\text{cryst}}$ denotes the period ring of crystalline representations defined by Fontaine [Fo1], and $\epsilon$ is induced by the natural inclusion $\mathbb{Q}_p(r) \hookrightarrow B_{\text{cryst}}$. The main result of this section is as follows

Theorem 9.1 Assume $0 \leq r \leq p - 2$ and Conjecture 8.11 for $D^i := D^i(Y)$. Then we have

$$\Phi^{i,r} \subset H^1_f(K, \mathcal{V}^i(r)).$$

Further if $r \geq \dim(X_K) - p + 3$, then we have $\Phi^{i,r} = H^1_f(K, \mathcal{V}^i(r))$. 

Documenta Mathematica 18 (2013) 177–247
Remark 9.2 When $X$ is smooth over $\mathcal{O}_K$, Theorem 9.1 is a part of the $p$-adic point conjecture raised by Schneider [Sc] and proved by Langer-Saito [LS] and Nekovár [Ne1].

Put

$$H^{i+1}(X, \tau_{\leq r} R_j^* \mathbb{Q}_p(r)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{\leftarrow n \geq 1} H^{i+1}(X, \tau_{\leq r} R_j^* \mu_{p^n}^{(r)})$$

and let $F^q H^{i+1}(X, \tau_{\leq r} R_j^* \mu_{p^n}^{(r)})$ be the inverse image of $F^q H^{i+1}(X, \mathbb{Q}_p(r))$ under the map

$$j^* : H^{i+1}(X, \tau_{\leq r} R_j^* \mu_{p^n}^{(r)}) \to H^{i+1}(X, \mathbb{Q}_p(r)).$$

We first prepare the following key commutative diagram to prove Theorem 9.1, assuming $0 \leq r \leq p-2$:

$$\begin{array}{c}
\xymatrix{
H^1(K, V^i (r)) \ar[r]^-{i} \ar[d]^-{\delta} & F^1 H^{i+1}(X, \tau_{\leq r} R_j^* \mathbb{Q}_p(r)) \ar[d]^-{\alpha} \\
H^1(K, V^i \otimes_{\mathbb{Q}_p} B_{\text{crys}}) \ar[r]^-{\delta} & D^i / ND^i \ar[r]^-{\epsilon} & E^i,
}\end{array}$$

where $E^i := E^i(Y)$ is as in (8.10.5), and $D^i / ND^i$ denotes the cokernel of the monodromy operator $N : D^i \to D^i$. The top arrow is induced by $j^*$ and an edge homomorphism of the spectral sequence (9.0.1). The arrow $\epsilon$ is induced by the complex (8.10.2), and the arrow $\sigma'$ is induced by the composite map

$$H^{i+1}(X, \tau_{\leq r} R_j^* \mu_{p^n}^{(r)}) \xrightarrow{\sigma} H^{i+1}(Y, \nu_{Y,n}^{-1}) \to H^i(Y, W_n \Xi_Y^*) \quad (n \geq 1).$$

See Theorem 3.4 for $\sigma$ and see Remark 8.5 for the last map. The constructions of the arrows $\alpha$ and $\delta$ and the commutativity of the square (A) deeply rely on the $p$-adic Hodge theory. The commutativity of the triangle (B) is rather straight-forward once we define $\alpha$ (see Proposition 9.10 below). The proof of Theorem 9.1 will be given after Proposition 9.10.

Remark 9.3 In his paper [La], Langer considered the diagram (A) assuming that $\mathcal{O}_K$ is absolutely unramified (loc. cit. Proposition 2.9). We remove this assumption and the assumption (*) stated in loc. cit. p. 191, using a continuous version of crystalline cohomology (see Appendix A below). For this purpose, we include a detailed construction of $\alpha$ and a proof of the commutativity of (A).

Construction of $\delta$. We first construct the map $\delta$. There is an exact sequence of topological $G_K$-$\mathbb{Q}_p$-modules

$$0 \to \mathcal{V}^i \otimes_{\mathbb{Q}_p} B_{\text{crys}} \to \mathcal{V}^i \otimes_{\mathbb{Q}_p} B_{\text{cris}} \xrightarrow{1 \otimes N} \mathcal{V}^i \otimes_{\mathbb{Q}_p} B_{\text{cris}} \to 0,$$  

(9.3.1)
where \( N \) denotes the monodromy operator on \( B_{st} \). Taking continuous Galois cohomology groups, we obtain a long exact sequence

\[
0 \rightarrow \left( \mathcal{Y}^i \otimes \mathbb{Q}_p \right) \otimes_{B_{st}} B_{crys}^G \rightarrow \left( \mathcal{Y}^i \otimes \mathbb{Q}_p \right) \otimes_{B_{st}} B_{crys}^G \rightarrow \left( \mathcal{Y}^i \otimes \mathbb{Q}_p \right) \otimes_{B_{st}} B_{crys}^G \rightarrow H^1(G_K, \mathcal{Y}^i \otimes \mathbb{Q}_p) \rightarrow \cdots.
\]

By the \( C_{st} \)-conjecture proved by Hyodo, Kato and Tsuji ([HK], [K4], [Ts1], cf. [Ni2]), the last arrow of the top row is identified with the map \( N : D^i \rightarrow D^i \) (see (9.3.3) below for the construction of \( C_{st} \)-isomorphisms). We thus define the desired map \( \delta \) as the connecting map of this sequence.

**\( C_{st} \)-isomorphism.** Before constructing \( \alpha \), we recall the construction of \( C_{st} \)-isomorphisms, which will be useful later ([K4], [Ts1] §4.10). See [K3] for the general framework of log structures and log schemes. Put

\[
W := W(k) \quad \text{and} \quad K_0 := \text{Frac}(W) = W[p^{-1}].
\]

For a log scheme \((Z, M_Z)\) and an integer \( n \geq 1 \), we define

\[
(Z_n, M_{Z_n}) := (Z, M_Z) \times_{\text{Spec}(Z)} \text{Spec}(\mathbb{Z}/p^n),
\]

where we regarded \( \text{Spec}(Z) \) and \( \text{Spec}(\mathbb{Z}/p^n) \) as log schemes by endowing them with the trivial log structures and the fiber product is taken in the category of log schemes. Let \( M \) be the log structure on \( X \) associated with the normal crossing divisor \( Y \). Let \( \overline{O}_K \) be the integral closure of \( O_K \) in \( K \), and let \( \overline{M} \) be the log structure on \( \overline{X} := X \otimes_{\overline{O}_K} O_K \) define by base-change (see (A.0.2) below). Put \( \overline{Y} := Y \otimes_k \overline{K} \). For \( n \geq 1 \) and \( s \geq 0 \), let \( J_{n}^{-1}(s)(\overline{X}, \overline{M}) \in D^+(\overline{Y}_{\overline{k}}, \mathbb{Z}/p^n) \) be Tsuji’s version of syntomic complex of \((\overline{X}, \overline{M})\) (§A.5). Let \( j : X_{\overline{M}} \rightarrow \overline{X} \) be the natural open immersion. For \( m, s \geq 0 \), we define the syntomic cohomology of \((\overline{X}, \overline{M})\) as

\[
H^m_{\text{syn}}((\overline{X}, \overline{M}), J_{n}^{-1}(s)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^m(\overline{Y}, J_{n}^{-1}(s)(\overline{X}, \overline{M})).
\]

The following isomorphism due to Tsuji ([Ts1] Theorem 3.3.4(2)) plays a crucial role:

\[
H^m_{\text{syn}}((\overline{X}, \overline{M}), J_{s}^{-1}(s)) \simeq H^m(\overline{X}, J_{s}^{-1}(s) \otimes_{\mathbb{Q}_p} \mathbb{Q}_p). \quad (9.3.2)
\]

The right hand side is isomorphic to \( Y^m(s) = H^m(X_{\overline{M}}, \mathbb{Q}_p(s)) \) if \( s \geq \dim(X_K) \) or \( s \geq m \). We now introduce the crystalline cohomology of \((\overline{X}, \overline{M})\) over \( W \):

\[
H^m_{\text{crys}}((\overline{X}, \overline{M})/W) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \geq 1} H^m_{\text{crys}}((\overline{X}_n, \overline{M}_n)/W_n),
\]

where \( H^m_{\text{crys}}((\overline{X}_n, \overline{M}_n)/W_n) \) denotes the crystal cohomology of \((\overline{X}_n, \overline{M}_n)\) over \( W_n \) (see §A.1 below). We define a \( G_K \)-equivariant homomorphism

\[
g^m : Y^m \rightarrow D^m \otimes_{K_0} B_{st}
\]
as the composite map \((d := \dim(X_K))\)

\[
\mathcal{Y}^m \xrightarrow{(1)} H^m_{\text{syn}}(\bar{X}, \bar{M}), \mathcal{Y}_p(d) \otimes \mathbb{Q}_p(-d) \quad (9.3.3)
\]

\[
\xrightarrow{(2)} H^m_{\text{cris}}((\bar{X}, \bar{M})/W) \otimes \mathbb{Q}_p(-d)
\]

\[
\xrightarrow{(3)} (D^m \otimes_{K_0} B^+_{\text{st}})^{N=0} \otimes \mathbb{Q}_p(-d)
\]

\[
\xrightarrow{(4)} D^m \otimes_{K_0} B_{\text{st}},
\]

where (1) is obtained from the isomorphism (9.3.2) with \(s = d\), the arrow (2) is the \(p^d\)-times of the canonical map induced by (A.5.2) below, and (3) is the crystalline interpretation of \((D^m \otimes_{K_0} B^+_{\text{st}})^{N=0}\) due to Kato ([K4] §4, cf. Proposition A.3.1 (3) below). The map (4) is induced by the natural inclusion \(\mathbb{Q}_p(-d) \hookrightarrow B_{\text{st}}\). The \(B_{\text{st}}\)-linear extension of \(g^m\) is an isomorphism by [Ts2] Theorem 4.10.2:

\[
\mathcal{Y}^m \otimes_{\mathbb{Q}_p} B_{\text{st}} \xrightarrow{\sim} D^m \otimes_{K_0} B_{\text{st}}, \quad (9.3.4)
\]

which we call the \(C_{\text{st}}\)-isomorphism. Now we have a commutative diagram of \(G_K\)-modules for \(m, s \geq 0\)

\[
\begin{array}{ccc}
H^m_{\text{syn}}((\bar{X}, \bar{M}), \mathcal{Y}_p(s)) & \xrightarrow{(1)} & H^m_{\text{cris}}((\bar{X}, \bar{M})/W) \otimes \mathbb{Q}_p \xrightarrow{\sim} (D^m \otimes_{K_0} B^+_{\text{st}})^{N=0} \\
\xrightarrow{(9.3.2)} & & \xrightarrow{(9.3.4)} \\
\mathcal{Y}^m(s) & \xrightarrow{\mathbb{Q}_p(s) \otimes B_{\text{st}}} & \mathcal{Y}^m \otimes_{\mathbb{Q}_p} B_{\text{st}} & \xrightarrow{\sim} & D^m \otimes_{K_0} B_{\text{st}}
\end{array}
\]

(9.3.5)

where the arrow (1) is the \(p^j\)-times of the canonical map (A.5.2), and (2) is the crystalline interpretation of \((D^m \otimes_{K_0} B^+_{\text{st}})^{N=0}\) mentioned in (9.3.3). This diagram commutes by the construction of (9.3.4) and the compatibility facts in [Ts1] Corollaries 4.8.8 and 4.9.2.

**Remark 9.4.** We modified the \(C_{\text{st}}\)-isomorphisms in [Ts1] by constant multiplications to make them consistent with the canonical map from syntomic cohomology of Kato to (continuous) crystalline cohomology (see the map (1) of (9.5.1) and the equality (A.5.4) below). Under this modification, the element \(t_{\text{syn}}\) in [Ts1] p. 378 is replaced with \(p^{-1}t_{\text{syn}}\), and Corollary 4.8.8 of loc. cit. remains true.

**Construction of \(\alpha\).** We start the construction of \(\alpha\) assuming \(0 \leq r \leq p - 2\), which will be complete in Corollary 9.8 below. For \(n \geq 1\), let \(\mathcal{Y}_n(r)_{(X, M)} \in D^+(Y_{\text{et}}, \mathbb{Z}/p^n)\) be the syntomic complex of Kato (see §A.5 below). Since \(0 \leq r \leq p - 2\), there is an isomorphism

\[
(\tau_{\leq r} R_{\mathcal{I}_n})|_Y \simeq \mathcal{Y}_n(r)_{(X, M)} \quad \text{in} \quad D^+(Y_{\text{et}}, \mathbb{Z}/p^n) \quad (9.4.1)
\]

for each \(n \geq 1\) ([Ts2] Theorem 5.1), and \(H^{i+1}(X, \tau_{\leq r} R_{\mathcal{I}_n})\) is isomorphic to the syntomic cohomology

\[
H^{i+1}_{\text{syn}}((X, M), \mathcal{Y}_p(r)) := \mathbb{Q}_p \otimes \mathbb{Z}_p \lim_{n \geq 1} H^{i+1}_{\text{syn}}(Y, \mathcal{Y}_n(r)_{(X, M)}).
\]
by the proper base-change theorem. Therefore we consider $H^i_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r))$ instead of $H^i(X, \tau_{\leq r} R_j, \mathbb{Q}_p(r))$, which is the major reason we assume $r \leq p - 2$.

We first prove:

**Lemma 9.5** The kernel of the composite map

$$\xi : H^m_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r)) \to H^m_{\text{cris}}((X, M)/W)_{Q_p} \to H^m_{\text{cris}}((\overline{X}, \overline{M})/W)_{Q_p}$$

agrees with that of the composite map

$$\eta : H^m_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r)) \overset{(9.4.1)}{\approx} H^m(X, \tau_{\leq r} R_j, \mathbb{Q}_p(r)) \to \mathcal{V}^m(r) = H^m(X, K, \mathbb{Q}_p(r)).$$

**Proof.** The map $\eta$ factors through (9.3.2) with $s = r$, and the map $\xi$ factors through the map (1) in (9.3.5) with $s = r$ by (A.5.4) below. Hence the diagram

$$\begin{array}{ccc}
H^m_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r)) & \xrightarrow{\xi} & H^m_{\text{cris}}((\overline{X}, \overline{M})/W)_{Q_p} \\
\eta \downarrow & & \downarrow \\
\mathcal{V}^m(r) & \rightarrow & D^m \otimes_{Q_p} B_{\text{st}}
\end{array}$$

commutes by (9.3.5), which implies the assertion. \qed

Let $H^m_{\text{cont-cr}}((X, M)/W)$ be the continuous crystalline cohomology of $(X, M)$ over $W$ (see §A.2 below). Put

$$H^m_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r))^0 := \ker(\eta : H^m_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r)) \to \mathcal{V}^m(r)),$$

$$H^m_{\text{cont-cr}}((X, M)/W)_{Q_p} := Q_p \otimes_{Q_p} H^m_{\text{cont-cr}}((X, M)/W),$$

$$H^m_{\text{cont-cr}}((X, M)/W)_0^0 := \ker(H^m_{\text{cont-cr}}((X, M)/W)_{Q_p} \to H^m_{\text{cris}}((\overline{X}, \overline{M})/W)_{Q_p}).$$

There are canonical maps

$$H^i_{\text{syn}}((X, M), \mathcal{I}_{Q_p}(r))^0 \xrightarrow{(1)} H^i_{\text{cont-cr}}((X, M)/W)^0_{Q_p} \xrightarrow{(2)} H^i(K, H^i_{\text{cris}}((\overline{X}, \overline{M})/W)_{Q_p})$$

$$\xrightarrow{(3)} H^i(K, (D^f \otimes_{K_0} B_{\text{st}}^+)_{N=0}) \xrightarrow{(4)} H^i(K, \mathcal{V}^i \otimes_{Q_p} B_{\text{cris}}),$$

where (1) is the canonical map obtained from Lemma 9.5 and Proposition A.6.1 (2) below, the arrow (3) is the isomorphism (2) in (9.3.5) for $m = i$, and (4) is obtained from the $C_{\text{st}}$-isomorphism (9.3.4) and (9.3.1). The most crucial map (2) is obtained from an edge homomorphism of the spectral sequence in Theorem A.4.2 (see also Corollary A.4.5 below). To proceed with the construction of $\alpha$, we need to introduce some notation.
Definition 9.6  Put $S := \text{Spec}(O_K)$, and fix a prime $\pi$ of $O_K$. Let $M_S$ be the log structure on $S$ associated with the closed point \{ $\pi = 0$ \}. Put $V := \text{Spec}(W[t])$, and let $M_V$ be the log structure on $V$ associated with the divisor \{ $t = 0$ \}. Let $t : (S, M_S) \rightarrow (V, M_V)$ be the exact closed immersion over $W$ sending $t \mapsto \pi$. For each $n \geq 1$, let $(\delta_n, M_{\delta_n})$ be the PD-envelope of the exact closed immersion $\iota_n : (V_n, M_{V_n}) \hookrightarrow (S_n, M_{S_n})$ compatible with the canonical PD-structure on $pW_n$. We define

$$H^m_{\text{crys}}((X, M)/(\delta', M_{\delta'}))_{Q_p} := \lim_{n \rightarrow \infty} H^m_{\text{crys}}((X_n, M_n)/(\delta_n, M_{\delta_n})),$$

which is an $R_{\delta'} := \lim_{n \rightarrow \infty} \Gamma(\delta_n, O_{\delta_n})$-module endowed with a $\varphi_{\delta'}$-semilinear endomorphism $\varphi$ and a $K_0$-linear endomorphism $N$ satisfying $N\varphi = p\varphi N$. Here $\varphi_{\delta'}$ is a certain canonical Frobenius operator on $R_{\delta'}$. See [Ts1] p. 253 for $\varphi_{\delta'}$, loc. cit. §4.3 for $N$ and $\varphi$, and see loc. cit. Remark 4.3.9 for $N$.

The following lemma plays a key role in our construction of $\alpha$, where we do not need to assume $0 \leq r \leq p - 2$ (compare with the assumption (+) in [La] p. 191).

Lemma 9.7  (1) There exists a long exact sequence

$$\cdots \rightarrow H^i_{\text{cont-cr}}((X, M)/W)_{Q_p} \rightarrow H^i_{\text{crys}}((X, M)/(\delta', M_{\delta'}))_{Q_p} \rightarrow H^i_{\text{cont-cr}}((X, M)/W)_{Q_p} \rightarrow \cdots$$

$$N \rightarrow H^i_{\text{crys}}((X, M)/(\delta', M_{\delta'}))_{Q_p} \rightarrow H^{i+1}_{\text{cont-cr}}((X, M)/W)_{Q_p} \rightarrow \cdots$$

and the image of $\partial$ agrees with $H^{i+1}_{\text{cont-cr}}((X, M)/W)_{Q_p}$.

(2) There is a commutative diagram whose lower row is exact

$$\begin{array}{ccc}
D^i & \longrightarrow & H^1_{\text{cont-cr}}((X, M)/W)_{Q_p}^0 \\
N & \downarrow & \delta \\
D^i & \longrightarrow & H^1(K, \mathcal{Y} \otimes_{Q_p} B_{\text{crys}}) \\
\end{array}$$

Here the right vertical arrow is the composite of (2)–(4) in (9.5.1), and the left vertical arrow is the specialization maps with $t \mapsto 0$ (cf. [Ts1] (4.4.4)).

Proof. (1) follows from Proposition A.2.4 and Corollaries A.3.2 (1) and A.3.4 below. As for (2), the exactness of the lower row has been explained in the construction of $\delta$. See Corollary A.4.5 below for the commutativity of the square.

Corollary 9.8  The composite map (9.5.1) factors as follows:

$$H^{i+1}_{\text{syn}}((X, M), \mathcal{Y}_{Q_p}(r))^0 \longrightarrow D^i/N D^i \delta \longrightarrow H^1(K, \mathcal{Y} \otimes_{Q_p} B_{\text{crys}}).$$

We define $\alpha$ as the first arrow of this decomposition.
Commutativity of the diagram (9.2.1). We first prove that the square (A) in (9.2.1) is commutative. By the construction of $\alpha$ and $\delta$, it is enough to show

**Theorem 9.9** The following square is commutative:

$$
\begin{array}{c}
H^{i+1}_\text{syn}(X, M), \mathcal{S}_p(r))_0 \xrightarrow{\varphi} F^1 H^{i+1}(X, \tau_{\leq r}, R_j \mathbb{Q}_p(r)) \\
\downarrow (9.5.1) \\
H^1(K, \mathcal{V}^i \otimes \mathbb{Q}_p B_{\text{crys}}) \xrightarrow{B_{\text{crys}} \leftarrow \mathbb{Q}_p(r)} H^1(K, \mathcal{V}^i(r)),
\end{array}
$$

where the right vertical arrow is the top arrow in (9.2.1).

**Proof.** Put $d := \dim(X_K)$. We define a $G_K$-homomorphism

$$
\beta^{i,r} : \mathcal{V}^i(r) \longrightarrow \begin{cases} H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}(r - d) & \text{(if } r < d) \\ H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p} & \text{(if } r \geq d) \end{cases}
$$

as the following composite map for $r \geq d$:

$$
\mathcal{V}^i(r) \xrightarrow{9.3.2} H^{i+1}_\text{syn}(X, M), \mathcal{S}_p(r))_0 \xrightarrow{9.5.1(1)} H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p},
$$

and as the following map for $r < d$:

$$
\mathcal{V}^i(r) \simeq \mathcal{V}^i(d) \otimes_{\mathbb{Q}_p} \mathbb{Q}_p(r - d) \xrightarrow{\beta^{i,d} \otimes \text{id}} H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}(r - d).
$$

We next define a homomorphism

$$
\gamma^{i,r} : H^{i+1}_\text{syn}(X, M), \mathcal{S}_p(r))_0 \longrightarrow \begin{cases} H^1(K, H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}(r - d)) & \text{(if } r < d) \\ H^1(K, H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}) & \text{(if } r \geq d) \end{cases}
$$

as the following composite map, if $r < d$:

$$
H^{i+1}_\text{syn}(X, M), \mathcal{S}_p(r))_0 \xrightarrow{(i)} H^1(K, H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}) \simeq H^1(K, H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}(r - d) \otimes_{\mathbb{Q}_p} \mathbb{Q}_p(d - r)) \xrightarrow{(ii)} H^1(K, H^i_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}(r - d)),
$$

where (i) is the composite of (1) and (2) in (9.5.1), and (ii) is induced by the inclusion $\mathbb{Q}_p(d - r) \hookrightarrow H^0_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}$ (cf. (A.6.5) below) and the cup product of crystalline cohomology. If $r \geq d$, then we define $\gamma^{i,r}$ as the composite of (1) and (2) in (9.5.1).
We prove the commutativity of (9.9.1) assuming \( r < d \). In this case, the following triangle commutes by Theorem A.6.7 below:

\[
H_{\text{syn}}^{i+1}((X, M), \mathscr{F}_p(r))^0 \xrightarrow{\gamma^{i, r}} H^1(K, \mathscr{F}^i(r)) \xrightarrow{\beta^{i, r}} H^1(K, H^1_{\text{crys}}(\overline{(X, M)}/W)_{Q_p}(r - d)),
\]  

(9.9.2)

where the left vertical arrow is the composite of the top horizontal and the right vertical arrows of (9.9.1). Moreover the following square commutes by the construction of the \( C_{\text{st}} \)-isomorphism (9.3.4) (compare with (9.3.5)):

\[
\begin{array}{ccc}
\gamma^{i, r} & \rightarrow & \beta^{i, r} \\
\downarrow & & \downarrow \\
H^1(K, \mathscr{F}^i(r)) & \rightarrow & H^1(K, \mathscr{F}^i(r)) \otimes_{Q_p} B_{\text{crys}}(Q_p(r) - d) \\
\end{array}
\]  

(9.9.3)

The commutativity of (9.9.1) follows from these commutative diagrams and the fact that the composite map (9.5.1) agrees with the composite of \( \gamma^{i, r} \) and the map

\[
H^1(K, H^1_{\text{crys}}(\overline{(X, M)}/W)_{Q_p}(r - d)) \rightarrow H^1(K, \mathscr{F}^i(r) \otimes_{Q_p} B_{\text{crys}}(Q_p(r)) -d)
\]

induced by the right vertical arrow and the bottom isomorphism in (9.9.3).

When \( r \geq d \), the following triangle commutes by Corollary A.6.3 below:

\[
H_{\text{syn}}^{i+1}((X, M), \mathscr{F}_p(r))^0 \xrightarrow{\gamma^{i, r}} H^1(K, \mathscr{F}^i(r)) \xrightarrow{\beta^{i, r}} H^1(K, H^1_{\text{crys}}((X, M)/W)_{Q_p}),
\]

where the left vertical arrow is defined in the same way as for that of (9.9.2). The commutativity of (9.9.1) follows from this diagram and the diagram (9.3.5). This completes the proof of Theorem 9.9.

Proposal 9.10 The triangle (B) in (9.2.1) is commutative.

Proof. There is a commutative diagram by the definition of \( \partial \) in Proposition A.2.4

\[
\begin{array}{ccc}
H^i_{\text{crys}}((X, M)/ (\mathscr{E}, M_{\mathscr{E}}))_{Q_p} & \xrightarrow{\partial} & D^i \\
\downarrow & & \downarrow \delta \wedge \\
H^i_{\text{cont}}((X, M)/ W)_{Q_p} & \xrightarrow{\partial} & D^{i+1}
\end{array}
\]

\[\text{Documenta Mathematica 18 (2013) 177–247}\]
where $\tilde{D}^{i+1} = \tilde{D}^{i+1}(Y)$ is as in the proof of Theorem 8.12, the left (resp. right) vertical arrow is as in Lemma 9.7 (1) (resp. given by the product with $d\log(t)$, cf. (8.9.1)), and the horizontal arrows are the specialization maps by $t \mapsto 0$. Therefore in view of the constructions of $\alpha$ and $\sigma'$, it is enough to check that the following diagram of canonical morphisms commutes in $D^+(Y_{\text{ét}}, \mathbb{Z}/p^n)$ for each $n \geq 0$:

\[
\begin{array}{c}
\tau \downarrow \\
\mathcal{F}_n(r)(X,M) \rightarrow \mathbb{Q}_p^{\geq r} \rightarrow W_n \mathbb{Q}_p^{r} \\
\sigma \downarrow \\
\mathbb{Q}_{Y/n}^{r-1}[-r] \rightarrow W_n \mathbb{Q}_p^{\geq r-1}[-1] \rightarrow W_n \mathbb{Q}_p[-1],
\end{array}
\]

where $\mathbb{Q}_{Y/n}^{r-1}$ is as in §A.5 below, and $s$ denotes the specialization map by $t \mapsto 0$. The right square commutes obviously in the category of complexes of sheaves.

As for the left square, we have only to show the commutativity on the diagram of the $r$-th cohomology sheaves because $W_n \mathbb{Q}_p^{\geq r-1}[-1]$ is concentrated in degrees $\geq r$ and $\mathcal{F}_n(r)(X,M)$ is concentrated in degrees $\leq r$ by (9.4.1). Since we have

\[
\mathcal{H}^r(\mathcal{F}_n(r)(X,M)) \simeq (R^r j_* \mathbb{Q}_p^{\geq r})||(Y)
\]

and the sheaf on the right hand side is generated by symbols (cf. the case $D = \emptyset$ of Theorem 3.3 (1)), one can check this commutativity of the diagram of sheaves by a straightforward computation on symbols using the compatibility in [Ts1] Proposition 3.2.4 (2).

**Proof of Theorem 9.1.** We have the following commutative diagram by (9.2.1):

\[
\begin{array}{c}
F^1 H^{i+1}(X, T) \rightarrow F^1 H^{i+1}(X, T \otimes \mathbb{Q}_p^r) \rightarrow E^1 \\
\alpha \downarrow \uparrow \downarrow \alpha' \\
H^1(K, \mathcal{F}^i(r)) \rightarrow D^1/N D^1 \\
\iota \downarrow \downarrow \downarrow \delta \\
H^1(K, \mathcal{F}^i \otimes \mathbb{Q}_p \mathcal{B}_{\text{crys}}) \\
\end{array}
\]

where the left triangle commutes obviously. The kernel of $\iota$ is $H^1_f(K, \mathcal{F}^i(r))$ by definition. The top row is a complex by the definitions of $\sigma'$ and $\Sigma_n(r)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]

by a simple diagram chase on this diagram. To obtain the second assertion, we repeat the same arguments for $\Phi^{2d-i,d-r+1}$, where we put $d := \dim(X_K)$. The map $\epsilon$ is injective by Theorem 8.12 and Conjecture 8.11 for $D^1$. We obtain the first assertion

\[
\Phi_i \subset H^1_f(K, \mathcal{F}^i(r))
\]
is injective by Conjecture 8.11 for $D^i$, Theorems 8.12 and 8.8 and the Poincaré duality between $D^i$ and $D^{2d-i}$ [Hy2]. Hence we have

$$\Phi^{2d-i,d-r+1} \subset H^1_f(K, \mathcal{R}^{2d-i}(d-r+1)).$$  \hfill (9.10.2)

The results (9.10.1) and (9.10.2) imply $\Phi^{i,r} = H^1_f(K, \mathcal{R}^i(r))$, because $\Phi^{i,r}$ and $\Phi^{2d-i,d-r+1}$ (resp. $H^1_f(K, \mathcal{R}^i(r))$ and $H^1_f(K, \mathcal{R}^{2d-i}(d-r+1))$) are the exact annihilators of each other under the non-degenerate pairing of the Tate duality

$$H^1_f(K, \mathcal{R}^i(r)) \times H^1_f(K, \mathcal{R}^{2d-i}(d-r+1)) \rightarrow \mathbb{Q}_p$$

by [Sa1] Corollary 10.6.1 (resp. [BK2] Proposition 3.8). \hfill \Box

10 \hskip 50pt \textbf{IMAGE OF P-ADIC REGULATORS}

In this section, we prove Theorem 1.1. We first review the definitions of the finite part of Galois cohomology [BK2] and the integral part of algebraic $K$-groups [Sch] over number fields.

Let $K$ be a number field and let $\mathcal{R}$ be a topological $G_K$-$\mathbb{Q}_p$-module which is finite-dimensional over $\mathbb{Q}_p$. Let $\mathfrak{o}$ be the integer ring of $K$. For a place $v$ of $K$, let $K_v$ (resp. $\mathfrak{o}_v$) be the completion of $K$ (resp. $\mathfrak{o}$) at $v$. The finite part $H^1_f(K, \mathcal{R}) \subset H^1(K, \mathcal{R})$ is defined as

$$H^1_f(K, \mathcal{R}) := \ker \left( H^1(K, \mathcal{R}) \rightarrow \prod_{v \text{ finite}} H^1(K_v, \mathcal{R}) \right),$$

where $v$ runs through all finite places of $K$, and $H^1_f(K_v, \mathcal{R})$ is defined as follows:

$$H^1_f(K_v, \mathcal{R}) := \begin{cases} \ker(H^1(K_v, \mathcal{R}) \rightarrow H^1(I_v, \mathcal{R})) & \text{if } \mathfrak{o}_v \not\subset \mathfrak{p}, \\ \ker(H^1(K_v, \mathcal{R}) \rightarrow H^1(K_v, \mathcal{R} \otimes \mathbb{Q}_p \text{Br}_\mathfrak{o}_v)) & \text{if } \mathfrak{o}_v \subset \mathfrak{p}, \end{cases}$$

where $I_v$ denotes the inertia subgroup of $G_K$. We next review the definition of the integral part of algebraic $K$-groups. Let $V$ be a proper smooth variety over the number field $K$. First fix a finite place $v$ of $K$. By de Jong’s alteration theorem [dJ], there is a proper generically finite morphism

$$\pi : V' \rightarrow V_v := V \otimes_K K_v$$

such that $V'$ has a projective regular model $X'$ with strict semistable reduction over the integer ring of some finite extension of $K_v$. The integral part $K_m(V_v)_{\mathfrak{o}_v} \subset K_m(V_v) \otimes \mathbb{Q}$ is the kernel of the composite map

$$K_m(V_v) \otimes \mathbb{Q} \xrightarrow{\pi^*} K_m(V') \otimes \mathbb{Q} \rightarrow \text{Image of } K_m(X') \otimes \mathbb{Q},$$

which is in fact independent of $X'$ ([Sch] §1). The integral part $K_m(V)_{\mathfrak{o}}$ is defined as

$$K_m(V)_{\mathfrak{o}} := \ker \left( K_m(V) \otimes \mathbb{Q} \rightarrow \prod_{v \text{ finite}} K_m(V_v) \otimes \mathbb{Q} \right),$$

$\text{Image of } K_m(X') \otimes \mathbb{Q}$.
where $v$ runs through all finite places of $K$. If $V$ admits a regular model which is proper flat over the integer ring of $K$, then $K_m(V)_\omega$ agrees with the image of the $K$-group of the model, i.e., the integral part considered by Beilinson. By these definitions of $H^i_\omega(K, V')$ and $K_{2r-i-1}(V)_\omega$, Theorem 1.1 is immediately reduced to Theorem 10.1 below, which is an analogue of Theorem 1.1 over local fields.

Let $\ell$ and $p$ be prime numbers. We change the setting slightly, and let $K$ be an $\ell$-adic local field, i.e., a finite extension of $\mathbb{Q}_\ell$. Let $O_K$ be the integer ring of $K$, and let $V$ be a proper smooth variety over $K$. Let $i$ and $r$ be integers with $2r \geq i + 1 \geq 1$.

There is a $p$-adic regulator map obtained from étale Chern character

$$\text{reg}_p : K_{2r-i-1}(V)_{O_K, \text{hom}} \to H^1(K, H^i(\mathbb{V}, \mathbb{Q}_p(r))),$$

where $\mathbb{V}$ denotes $V \otimes_K \mathbb{F}_p$, and $K_{2r-i-1}(V)_{O_K, \text{hom}}$ denotes the subspace of $K_{2r-i-1}(V)_{O_K}$ consisting of all elements which vanish in $H^{i+1}(\mathbb{V}, \mathbb{Q}_p(r))$ under the Chern character.

**Theorem 10.1** If $\ell = p$, assume that $r \leq p - 2$ and that Conjecture 8.11 holds for projective strict semistable varieties over $\mathbb{F}_p$ in degree $i$. Then $\text{Im}(\text{reg}_p)$ is contained in $H^1_\omega(K, H^i(\mathbb{V}, \mathbb{Q}_p(r)))$.

**Remark 10.2** When $\ell = p$, we need Conjecture 8.11 for the reduction of an alteration of $V$. When $\ell \neq p$, we do not need the monodromy-weight conjecture, but use Deligne’s proof of the Weil conjecture [D] to show that $\text{reg}_p$ is zero.

**Proof of Theorem 10.1.** We first reduce the problem to the case that $V$ has a regular model which is projective flat over $O_K$ with strict semistable reduction. By de Jong’s alteration theorem [dJ], there exists a proper generically finite morphism $\pi : V' \to V$ such that $V'$ has a projective regular model with strict semistable reduction over the integer ring $O_L$ of $L := \Gamma(V', \mathcal{O}_{V'})$. Then there is a commutative diagram

$$\begin{array}{ccc}
K_{2r-i-1}(V)_{O_K, \text{hom}} & \xrightarrow{\pi^*} & H^1(K, H^i(\mathbb{V}, \mathbb{Q}_p(r))) \\
\xrightarrow{\text{reg}_p} & & \xrightarrow{\pi^*} \\
K_{2r-i-1}(V')_{O_L, \text{hom}} & \xrightarrow{\text{reg}_p} & H^1(L, H^i(\mathbb{V}', \mathbb{Q}_p(r))) \\
\end{array}$$

where $\mathbb{V}'$ denotes $V' \otimes_L \mathbb{F}_p$, and the right (and the middle) vertical arrows are split injective by a standard argument using a corestriction map of Galois cohomology and a trace map of étale cohomology. By this diagram and the definition of $K_\omega(V)_{O_K}$, Theorem 10.1 for $V$ is reduced to that for $V'$. Thus we may assume that $V$ has a projective regular model $X$ with strict semistable reduction over $O_K$. Then the case $\ell \neq p$ follows from [Ne1] II Theorem 2.2 (cf. [D]). We prove the case $\ell = p$. Let $Y$ be the reduction of $X$. Put

$$H^{i+1}(X, \Omega_{\mathbb{Q}_p}(r)) := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} \lim_{n \to \infty} H^{i+1}(X, \Omega_n(r)),$$
and let $K_{2r−i−1}(X)_{\text{hom}}$ (resp. $H^{i+1}(X, \mathbb{Q}_p(r))^0$) be the kernel of the composite map

$$K_{2r−i−1}(X) \to K_{2r−i−1}(V) \xrightarrow{ch} H^{i+1}(V, \mathbb{Q}_p(r)) \to H^{i+1}(\overline{V}, \mathbb{Q}_p(r))$$

(resp. $H^{i+1}(X, \mathbb{Q}_p(r)) \to H^{i+1}(V, \mathbb{Q}_p(r)) \to H^{i+1}(\overline{V}, \mathbb{Q}_p(r))$).

There is a commutative diagram by Corollary 5.7

$$
\begin{array}{ccc}
K_{2r−i−1}(X)_{\text{hom}} & \rightarrow & K_{2r−i−1}(V)_{\text{O_K, hom}} \\
\downarrow & & \downarrow ch \\
H^{i+1}(X, \mathbb{Q}_p(r))^0 & \rightarrow & H^1(K, H^i(\overline{V}, \mathbb{Q}_p(r)))
\end{array}
$$

The image of the bottom arrow is contained in $H^1(K, H^i(\overline{V}, \mathbb{Q}_p(r)))$ by Theorem 9.1 and Conjecture 8.11 for $D^i = D^i(Y)$, which implies Theorem 10.1. This completes the proof of Theorems 10.1 and 1.1. □

A Continuous crystalline cohomology

In this appendix, we formulate continuous versions of crystalline and syntomic cohomology of log schemes, combining the methods of Jannsen, Kato and Tsuji ([J], [K2], [K3], [Ts1], [Ts2]). The results of this appendix have been used in §9 of this paper. See [K3] for the general framework of log structures and log schemes.

Let $p$ be a prime number, and let $K$ be a complete discrete valuation field of characteristic 0 whose residue field $k$ is a perfect field of characteristic $p$. Let $O_K$ be the integer ring of $K$. Put $W := W(k)$, $W_n := W_n(k) (n \geq 1)$ and $K_0 := \text{Frac}(W)$. Let $X$ be a regular scheme which is projective flat over $O_K$ with semistable reduction, and put

$$
X_K := X \otimes_{O_K} K, \quad Y := X \otimes_{O_K} k \\
X_{\overline{K}} := X_K \otimes_K \overline{K}, \quad \overline{Y} := Y \otimes_k \overline{K} \quad \text{and} \quad \overline{X} := X \otimes_{O_K} \overline{O_K},
$$

where $\overline{O_K}$ denotes the integral closure of $O_K$ in $\overline{K}$. Let $M$ be the log structure on $X$ associated with the normal crossing divisor $Y$. We endow $\overline{X}$ with a log structure $\overline{M}$ as follows. For a finite field extension $L/K$, put $S_L := \text{Spec}(O_L)$, and let $M_{S_L}$ be the log structure on $S_L$ associated with its closed point. We denote $(S_K, M_{S_K})$ simply by $(S, M_S)$, and define $(X_{O_L}, M_{O_L})$ by base-change in the category of log schemes

$$
(X_{O_L}, M_{O_L}) := (X, M) \times_{(S, M_S)} (S_L, M_{S_L}). \quad (A.0.1)
$$

We then define the log structure $\overline{M}$ on $\overline{X}$ as that associated with the pre-log structure

$$
\lim_{K \subset L \subset \overline{K}} M_{O_L | \overline{X}}, \quad (A.0.2)
$$
where \( L \) runs through all finite field extensions of \( K \) contained in \( \overline{K} \), \( M_{O_L} \mid \overline{K} \) denotes the topological inverse image of \( M_{O_L} \) onto \( \overline{K} \), and the inductive limit is taken in the category of étale sheaves of monoids on \( \overline{X} \).

For a log scheme \((Z, M_Z)\) and an integer \( n \geq 1\), we define

\[
(Z_n, M_{Z_n}) := (Z, M_Z) \times_{\text{Spec}(\mathbb{Z})} \text{Spec}(\mathbb{Z}/p^n),
\]

where we regarded \( \text{Spec}(\mathbb{Z}) \) and \( \text{Spec}(\mathbb{Z}/p^n) \) as log schemes by endowing them with the trivial log structures and the fiber product is taken in the category of log schemes.

We denote by \( \text{Mod}(\mathbb{Z}) \) and \( \text{Spec}(\mathbb{Z}/p^n) \) as log schemes by endowing them with the trivial log structures and the fiber product is taken in the category of log schemes.

For a scheme \( T \), \( \text{Shv}(T, \mathbb{Z}/p^*) \) denotes the category of the projective systems \( \{F_n\}_{n \geq 1} \) of \( \mathbb{Z}/p^n \)-sheaves on \( T \) such that \( F_n \) is a \( \mathbb{Z}/p^n \)-module for each \( n \geq 1 \). For a pro-finite group \( G \), \( \text{Mod}(G, \mathbb{Z}/p^*) \) denotes the category of the projective systems \( \{F_n\}_{n \geq 1} \) of discrete \( G \)-modules such that \( F_n \) is a \( \mathbb{Z}/p^n \)-module.

For a scheme \( T \), \( \text{Shv}(T, \mathbb{Z}/p^*) \) denotes the category of the projective systems \( \{F_n\}_{n \geq 1} \) of étale sheaves on \( T \) such that \( F_n \) is a \( \mathbb{Z}/p^n \)-sheaf for each \( n \geq 1 \). For a pro-finite group \( G \) acting on \( T \), \( \text{Shv}(T, G, \mathbb{Z}/p^*) \) denotes the category of the projective systems \( \{F_n\}_{n \geq 1} \) of étale \( G \)-sheaves on \( T \) such that \( F_n \) is a \( \mathbb{Z}/p^n \)-sheaf for each \( n \geq 1 \). We write \( D(T, \mathbb{Z}/p^*) \) (resp. \( D(T, G, \mathbb{Z}/p^*) \)) for the derived category of \( \text{Shv}(T, \mathbb{Z}/p^*) \) (resp. \( \text{Shv}(T, G, \mathbb{Z}/p^*) \)).

For an additive category \( \mathcal{E} \), we write \( \mathbb{Q} \otimes \mathcal{E} \) for the \( \mathbb{Q} \)-tensor category of \( \mathcal{E} \), i.e., the category whose objects are the same as \( \mathcal{E} \) and such that for objects \( A, B \in \mathcal{E} \), the group of morphisms \( \text{Hom}_{\mathbb{Q} \otimes \mathcal{E}}(A, B) \) is given by \( \mathbb{Q} \otimes \text{Hom}_{\mathcal{E}}(A, B) \). We often write \( \mathbb{Q} \otimes A \) for \( A \in \mathcal{E} \) regarded as an object of \( \mathbb{Q} \otimes \mathcal{E} \) to avoid confusions.

### A.1 Crystalline complexes

We construct the following objects:

\[
\begin{align*}
\mathcal{E}(X^*_\alpha, M_\alpha)/W_n \otimes_{\mathcal{E}(X^*_\alpha, M_\alpha)/(\mathcal{E}_\alpha, M_{\mathcal{E}_\alpha})} & \in D^+(Y_{\text{et}}, \mathbb{Z}/p^*) \\
\mathcal{E}(X^*_\alpha, \mathcal{M}_\alpha)/W_n \otimes_{\mathcal{E}(X^*_\alpha, \mathcal{M}_\alpha)/(\mathcal{E}_\alpha, M_{\mathcal{E}_\alpha})} & \in D^+(Y_{\text{et}}, G_{K-\mathbb{Z}/p^*}),
\end{align*}
\]

where \( W_n \) means \( \text{Spec}(W_n) \) endowed with the trivial log structure for each \( n \geq 1 \). See Definition 9.6 for \( (\mathcal{E}_\alpha, M_{\mathcal{E}_\alpha}) \). To construct \( \mathcal{E}(X^*_\alpha, M_\alpha)/W_n \), we fix an étale hypercovering \((X^*, M^*) \hookrightarrow (X, M)\) and a closed immersion \((X^*, M^*) \hookrightarrow (Z^*, M_{Z^*})\) of simplicial fine log schemes over \( W \) such that \((Z^*, M_{Z^*})\) is smooth over \( W \) for each \( i \in \mathbb{N} \) (cf. [HK] (2.18)). Put

\[
Y^* := X^* \otimes_{\mathcal{O}_{X^*}} k,
\]

which is an étale hypercovering of \( Y \). For \( n \geq 1 \), let \( (\mathcal{D}_n^*, M_{\mathcal{D}_n^*}) \) be the PD-envelope of \((X^*_n, M_{X^*_n}) \hookrightarrow (Z^*_n, M_{Z^*_n})\) with respect to the canonical PD-structure on \((p) \subset W_n\) ([K3] Definition 5.4), and we define a complex \( \mathcal{E}(X^*_n, M_{X^*_n})/W_n \) of sheaves on \( Y_{\text{et}}^* \) as

\[
\begin{align*}
\mathcal{O}_{\mathcal{D}_n^*} & \xrightarrow{d} \mathcal{O}_{\mathcal{D}_n^*} \otimes \mathcal{O}_{\mathcal{D}_n^*} \omega_{(Z^*_n, M_{Z^*_n})}/W_n \xrightarrow{d} \cdots \xrightarrow{d} \mathcal{O}_{\mathcal{D}_n^*} \otimes \mathcal{O}_{\mathcal{D}_n^*} \omega_{(Z^*_n, M_{Z^*_n})}/W_n \xrightarrow{d} \cdots,
\end{align*}
\]

where the first term is placed in degree 0 and \( \omega_{(Z^*_n, M_{Z^*_n})}/W_n \) denotes the \( q \)-th differential module of \((Z^*_n, M_{Z^*_n})\) over \( W_n \) cf. [K3] (1.7). See loc. cit. Theorem 6.2 for \( d \).
Regarding this complex as a complex of projective systems (with respect to $n \geq 1$) of sheaves on $Y_{\text{et}}$, we obtain a complex $E_{(X^\bullet, M^\bullet)}/W^\bullet$ of objects of $\text{Shv}(Y_{\text{et}}^\bullet, \mathbb{Z}/p^\bullet)$. We then define

$$E_{(X^\bullet, M^\bullet)}(V, M_S) := R\theta_v(E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)) \in D^+(V_{\text{et}}),$$

where $\theta : \text{Shv}(Y_{\text{et}}^\bullet, \mathbb{Z}/p^\bullet) \to \text{Shv}(Y_{\text{et}}^\bullet, \mathbb{Z}/p^\bullet)$ denotes the natural morphism of topoi. The resulting object $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ is independent of the choice of the pair $((X^\bullet, M^\bullet), (Z^\bullet, M_Z^\bullet))$ by a standard argument (cf. [K2] p. 212).

To construct $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$, we put $V := \text{Spec}(W[t])$, and define $M_V$ as the log structure on $V$ associated with the divisor $\{t = 0\}$. We regard $(X, M)$ as a log scheme over $(V, M_V)$ by the composite map

$$(X, M) \to (S, M_S) \to (V, M_V),$$

where the last map is given by $T \mapsto \pi$, the prime element of $O_K$ we fixed in Definition 9.6 to define $(\mathcal{E}_n, M_{\mathcal{E}_n})$. We then apply the same construction as for $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ to the morphism $(X, M) \to (V, M_V)$, i.e. fix an étale hypercovering $(X^\bullet, M^\bullet) \to (X, M)$ and a closed immersion $\iota^* : (X^\bullet, M^\bullet) \to (Z^\bullet, M_Z^\bullet)$ of simplicial log schemes over $(V, M_V)$ such that $(Z^\bullet, M_Z^\bullet)$ is smooth over $W$ for each $i \in \mathbb{N}$. We define $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ by replacing $\omega_{Z^\bullet, M_Z^\bullet}^\bullet(W^\bullet)$ with $\omega_{Z^\bullet, M_Z^\bullet}^\bullet(W^\bullet)$ in the above definition of $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$.

We construct $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ as follows. Fix an étale hypercovering $(X^\bullet, M^\bullet) \to (X, M)$ and for each finite extension $L/K$ contained in $K$, fix a closed immersion $(X^\bullet_{\text{et}}, M^\bullet_{\text{et}}) \hookrightarrow (Z^\bullet_L, M_Z^\bullet_L)$ of simplicial fine log schemes over $W$ such that $(Z^\bullet_L, M_Z^\bullet_L)$ is smooth over $W$ for each $i \in \mathbb{N}$ and $L/K$, and such that for finite extensions $L'/L$ there are morphisms $\tau_{L'/L} : (Z^\bullet_{L'}, M_Z^\bullet_{L'}) \to (Z^\bullet_L, M_Z^\bullet_L)$ satisfying transitivity. For a finite extension $L/K$, let $k_L$ be the residue field of $L$, and put

$$Y^\bullet_L := X^\bullet \otimes_{O_K} k_L \quad \text{and} \quad Y^\bullet := X^\bullet \otimes_{O_K} K,$

which are étale hypercoverings of $Y_L := Y \otimes_k k_L$ and $Y$, respectively. We define a complex $E_{(X^\bullet_{\text{et}}, M^\bullet_{\text{et}})}(V, M_S^\bullet)$ on $Y^\bullet_L$ applying the same construction as for $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ to the embedding $(X^\bullet_{\text{et}}, M^\bullet_{\text{et}}) \hookrightarrow (Z^\bullet_L, M_Z^\bullet_L)$, whose inverse image onto $Y^\bullet$ yields an inductive system of complexes of objects of $\text{Shv}(Y_{\text{et}}^\bullet, G_K \cdot \mathbb{Z}/p^\bullet)$ with respect to finite extensions $L/K$. We then define

$$E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet) := \lim_{\rightarrow} E_{(X^\bullet_{\text{et}}, M^\bullet_{\text{et}})}(V, M_S^\bullet),$$

where $\theta^\bullet : \text{Shv}(Y^\bullet_L, G_K \cdot \mathbb{Z}/p^\bullet) \to \text{Shv}(Y^\bullet_{\text{et}}, G_K \cdot \mathbb{Z}/p^\bullet)$ denotes the natural morphism of topoi. We construct $E_{(X^\bullet, M^\bullet)}(V, M_S^\bullet)$ applying similar arguments to the complexes $E_{(X^\bullet_{\text{et}}, M^\bullet_{\text{et}})}(V, M_S^\bullet)$.
We define the following objects of $\text{Mod}(\mathbb{Z}/p^*):$

\begin{align*}
H^i_{\text{crys}}((X_\bullet, M_\bullet)/W_\bullet) &:= R^i \Gamma(E_{(X_\bullet, M_\bullet)}/W_\bullet), \quad (A.1.1) \\
H^i_{\text{crys}}((X_\bullet, M_\bullet)/((\mathcal{E}_\bullet, M_{\mathcal{E}})_\bullet)) &:= R^i \Gamma(E_{(X_\bullet, M_\bullet)}/((\mathcal{E}_\bullet, M_{\mathcal{E}})_\bullet)), \quad (A.1.2) \\
H^i_{\text{crys}}((\overline{X}_\bullet, \overline{M}_\bullet)/W_\bullet) &:= R^i \mathcal{T}(E_{(\overline{X}_\bullet, \overline{M}_\bullet)}/W_\bullet), \quad (A.1.3) \\
H^i_{\text{crys}}((\overline{X}_\bullet, \overline{M}_\bullet)/((\mathcal{E}_\bullet, M_{\mathcal{E}})_\bullet)) &:= R^i \mathcal{T}(E_{(\overline{X}_\bullet, \overline{M}_\bullet)}/((\mathcal{E}_\bullet, M_{\mathcal{E}})_\bullet)), \quad (A.1.4)
\end{align*}

where $\Gamma$ and $\mathcal{T}$ denote the following left exact functors, respectively:

\begin{align*}
\Gamma &:= \Gamma(Y, -) : \text{Shv}(Y_{\text{et}}, \mathbb{Z}/p^*) \to \text{Mod}(\mathbb{Z}/p^*), \\
\mathcal{T} &:= \Gamma(Y, -) : \text{Shv}(Y_{\text{et}}, G_K\cdot\mathbb{Z}/p^*) \to \text{Mod}(G_K\cdot\mathbb{Z}/p^*). \quad (A.1.5)
\end{align*}

We define ‘naive’ crystalline cohomology groups

\begin{align*}
H^i_{\text{crys}}((X, M)/W), & \quad H^i_{\text{crys}}((X, M)/((\mathcal{E}, M_{\mathcal{E}}))), \\
H^i_{\text{crys}}((\overline{X}, \overline{M})/W) & \quad \text{and} \quad H^i_{\text{crys}}((\overline{X}, \overline{M})/((\mathcal{E}, M_{\mathcal{E}})))
\end{align*}

as the projective limit of (A.1.1)–(A.1.4), respectively.

**Remark A.1.6** Let $\pi_n : \text{Shv}(Y_{\text{et}}, \mathbb{Z}/p^n) \to \text{Shv}(Y_{\text{et}}, \mathbb{Z}/p^n)$ be the natural functor sending $\{\mathcal{F}_m\}_{m \geq 1}$ to $\mathcal{F}_n$. Since $\pi_n$ is exact, it extends to a triangulated functor $\pi_n : D^+(Y_{\text{et}}, \mathbb{Z}/p^n) \to D^+(Y_{\text{et}}, \mathbb{Z}/p^n)$, which sends $E_{(X_\bullet, M_\bullet)}/W_\bullet \mapsto E_{(X_\bullet, M_\bullet)}/W_\bullet$, an object computing the crystalline cohomology of $(X_\bullet, M_\bullet)/W_\bullet$, because $\pi_n$ is compatible with the gluing functor $\mathcal{T}$.

Moreover by [1] Proposition 1.1 (b), we have

\begin{align*}
H^i_{\text{crys}}((X_\bullet, M_\bullet)/W_\bullet) & \simeq \{H^i_{\text{crys}}((X_n, M_n)/W_n)\}_{n \geq 1}.
\end{align*}

We have similar facts for (A.1.2), (A.1.3) and (A.1.4) as well.

**A.2 Continuous crystalline cohomology**

We define continuous crystalline cohomology groups as follows:

\begin{align*}
H^i_{\text{cont-cr}}((X, M)/W) &:= R^i \left( \varprojlim \Gamma \right) (E_{(X_\bullet, M_\bullet)}/W_\bullet), \quad (A.2.1) \\
H^i_{\text{cont-cr}}((X, M)/((\mathcal{E}, M_{\mathcal{E}}))) &:= R^i \left( \varprojlim \Gamma \right) (E_{(X_\bullet, M_\bullet)}/((\mathcal{E}, M_{\mathcal{E}})_\bullet)), \quad (A.2.2)
\end{align*}

where $\Gamma$ is as in (A.1.5). Because $\Gamma$ has an exact left adjoint, it preserves injectives and there exists a spectral sequence

\[ E_{a,b}^2 = R^a \varprojlim \Gamma \left( H^b_{\text{crys}}((X_\bullet, M_\bullet)/W_\bullet) \right) \Rightarrow H_{\text{cont-cr}}^{a+b}((X, M)/W). \]

Because $R^a \varprojlim = 0$ for $a \geq 2$, this spectral sequence breaks up into short exact sequences

\[ 0 \to R^1 \varprojlim \Gamma \left( H^{i-1}_{\text{crys}} ((X_\bullet, M_\bullet)/W_\bullet) \right) \to H^i_{\text{cont-cr}}((X, M)/W) \to H^i_{\text{crys}}((X, M)/W) \to 0. \quad (A.2.3) \]

We have similar exact sequences for (A.2.2) by the same arguments.
There is a commutative diagram (see Definition 9.6 for $\mathcal{N}$)

\[
\begin{array}{c}
\lim \rightarrow & E(X, M^*)/W^n & \rightarrow & E(X, M^*)/(\mathcal{E}, M_{\mathcal{E}}) & \rightarrow & E(X, M^*)/W_n[1] \\
\end{array}
\]

in $D^+(Y_{\text{et}}, \mathbb{Z}/p^*)$. Consequently we obtain a long exact sequence

\[
\cdots \rightarrow H^{i}_{\text{cont-cr}}((X, M)/W) \rightarrow H^{i}_{\text{cont-cr}}((X, M)/(\mathcal{E}, M_{\mathcal{E}})) \rightarrow H^{i+1}_{\text{cont-cr}}((X, M)/W) \rightarrow \cdots.
\]

Proof. The assertion follows from the same arguments as in the proof of [K4] Lemma 4.2 with $\mathcal{F} = \mathcal{O}^{\text{cris}}$.

There is a commutative diagram (see Definition 9.6 for $\mathcal{N}$)

\[
\begin{array}{c}
H^{i}_{\text{cont-cr}}((X, M)/(\mathcal{E}, M_{\mathcal{E}})) & \rightarrow & H^{i}_{\text{cont-cr}}((X, M)/(\mathcal{E}, M_{\mathcal{E}})) \\
\downarrow & & \downarrow \\
H^{i}_{\text{cris}}((X, M)/(\mathcal{E}, M_{\mathcal{E}})) & \rightarrow & H^{i}_{\text{cris}}((X, M)/(\mathcal{E}, M_{\mathcal{E}})).
\end{array}
\]

We will show later that the vertical arrows are bijective in Corollary A.3.2 (1) below.

A.3 Comparison of projective systems of crystalline cohomology

We recall here the following comparison facts on projective systems of crystalline cohomology groups, which will be useful later. Note that for $A_* \in \text{Mod}(\mathbb{Z}/p^*)$, both $\lim A_*$ and $R^1 \lim A_*$ have finite exponents if $\mathbb{Q} \otimes (A_*) \simeq 0$ in $\mathbb{Q} \otimes \text{Mod}(\mathbb{Z}/p^*)$.

Proposition A.3.1 Let $i$ be a non-negative integer, and put $D^n_i := \mathbb{Q}(Y, \mathbb{W}_n \omega^n_\bullet)$.

Let $P_\bullet$ be the ring defined in [Ts1] §1.6, and put $R_{\mathcal{E}_n} := \Gamma(\mathcal{E}_n, \mathcal{O}_{\mathcal{E}_n})$.

1. There is an isomorphism in $\mathbb{Q} \otimes \text{Mod}(\mathbb{Z}/p^*)$

\[
\mathbb{Q} \otimes \{H^i_{\text{cris}}((X_*, M_*)/(\mathcal{E}, M_{\mathcal{E}}))\} \simeq \mathbb{Q} \otimes \{R_{\mathcal{E}_n} \otimes \mathbb{W}_n D^n_i\}_{n \geq 1}
\]

and $R^1 \lim H^i_{\text{cris}}((X_*, M_*)/(\mathcal{E}, M_{\mathcal{E}}))$ has a finite exponent.

2. There is an isomorphism in $\mathbb{Q} \otimes \text{Mod}(G_K \cdot \mathbb{Z}/p^*)$

\[
\mathbb{Q} \otimes \{H^i_{\text{cris}}((\overline{X_*, M_*)}/(\mathcal{E}, M_{\mathcal{E}}))\} \simeq \mathbb{Q} \otimes \{P_n \otimes \mathbb{W}_n D^n_i\}_{n \geq 1}
\]

and $R^1 \lim H^i_{\text{cris}}((\overline{X_*, M_*)}/(\mathcal{E}, M_{\mathcal{E}}))$ has a finite exponent.

3. There is an isomorphism in $\mathbb{Q} \otimes \text{Mod}(G_K \cdot \mathbb{Z}/p^*)$

\[
\mathbb{Q} \otimes \{H^i_{\text{cris}}((\overline{X_*, M_*)}/\mathbb{W}_n)\} \simeq \mathbb{Q} \otimes \{(P_n \otimes \mathbb{W}_n D^n_i)^N = 0\}_{n \geq 1}
\]

and $R^1 \lim H^i_{\text{cris}}((\overline{X_*, M_*)}/\mathbb{W}_n)$ has a finite exponent. Here $N$ acts on $P_n \otimes \mathbb{W}_n D^n_i$ by $N_{P_n} \otimes 1 + 1 \otimes N$ and $N_{P_n}$ denotes the monodromy operator on $P_n$, cf. [Ts1] p. 253.
Proof. (1) The first assertion follows from [HK] Lemma 5.2 (see also (*) in the proof of [Ts1] Proposition 4.4.6). To show the second assertion, we check that the projective system \( \{ R_{\mathfrak{d}_n} \otimes_{W_n} D_n \}_{n \geq 1} \) satisfies the Mittag-Leffler condition. Indeed, \( D_n \) is finitely generated over \( W_n \), and the projection \( R_{\mathfrak{d}_{n+1}} \to R_{\mathfrak{d}_n} \) is surjective by the presentation

\[
R_{\mathfrak{d}_n} = W[t, t^{\nu}/\nu! \ (\nu \geq 1)] \otimes_W W_n \quad (e := [K : K_0])
\]

obtained from the definition of \( (\mathfrak{d}_n, M_{\mathfrak{d}_n}) \) (see the proof of [Ts1] Proposition 4.4.6).

(2) The first assertion follows from that of (1) and [Ts1] Proposition 4.5.4. The second assertion follows from the fact that \( \{ P_n \otimes_{W_n} D_n \}_{n \geq 1} \) satisfies the Mittag-Leffler condition. Indeed, the natural projection \( P_{n+1} \to P_n \) is surjective (loc. cit. Lemma 1.6.7) and \( D_n \) is finitely generated over \( W_n \).

(3) See the proof of loc. cit. Proposition 4.5.6 for the first assertion. We show the second assertion. Note that \( P_n \) is flat over \( W_n \), because \( R_{\mathfrak{d}_n} \) is flat over \( W_n \) and \( P_n \) is flat over \( R_{\mathfrak{d}_n} \) by the above presentation of \( R_{\mathfrak{d}_n} \) and loc. cit. Proposition 4.1.5. Let \( \{ D_n \}_{n \geq 1} \) be a projective system of \( W \)-modules such that \( D_n \) is finitely generated over \( W_n \) for each \( n \), and let \( N : \{ D_n \}_{n \geq 1} \to \{ D_n \}_{n \geq 1} \) be a nilpotent \( W \)-endomorphism. Our task is to show that

\[
R^1 \lim \{ (P_n \otimes_{W_n} D_n)^{N=0} \}_{n \geq 1} = 0.
\]

Consider a short exact sequence of projective systems

\[
0 \to \{ (D_n)^{N=0} \}_{n \geq 1} \to \{ D_n \}_{n \geq 1} \to \{ N(D_n) \}_{n \geq 1} \to 0.
\]

Note that \( (D_n)^{N=0} \) and \( N(D_n) \) are finitely generated over \( W_n \) for each \( n \). Let \( b \) be the minimal integer for which \( N^b = 0 \) on \( \{ D_n \}_{n \geq 1} \). By [K4] Lemma 4.3 and the flatness of \( P_n \) over \( W_n \), we have a short exact sequence for each \( n \geq 1 \)

\[
0 \to (P_n \otimes_{W_n} (D_n)^{N=0})^{N=0} \to (P_n \otimes_{W_n} D_n)^{N=0} \to (P_n \otimes_{W_n} N(D_n))^{N=0} \to 0,
\]

which yields a short exact sequence of projective systems with respect to \( n \geq 1 \). Since \( N^{b-1} = 0 \) on \( \{ N(D_n) \}_{n \geq 1} \), we may assume \( b = 1 \) by induction on \( b \geq 1 \). Now let \( B_n \) be as in [Ts1] §1.6 and let \( A_{\text{cris}} \) be as in loc. cit. §1.1. Then we have isomorphisms

\[
(P_n \otimes_{W_n} D_n)^{N=0} \overset{(1)}{\cong} (P_n)^{N=0} \otimes_{W_n} D_n \overset{(2)}{\cong} B_n \otimes_{W_n} D_n \overset{(3)}{=} (A_{\text{cris}}/p^n) \otimes_{W_n} D_n,
\]

where (1) follows from the assumption \( b = 1 \) and the flatness of \( P_n \) over \( W_n \). The isomorphism (2) (resp. (3)) follows from loc. cit. Corollary 1.6.6 (resp. the definition of \( B_n \) in loc. cit. §1.6). Thus \( R^1 \lim \{ (P_n \otimes_{W_n} D_n)^{N=0} \}_{n \geq 1} \) is zero, and we obtain the assertion. \( \square \)

Corollary A.3.2. (1) For \( i \geq 0 \), we have

\[
H^i_{\text{cris}}((X, M)/(\mathfrak{d}, M_{\mathfrak{d}}))_{\mathbb{Q}_p} \simeq H^i_{\text{cont}-\text{cris}}((X, M)/(\mathfrak{d}, M_{\mathfrak{d}}))_{\mathbb{Q}_p}.
\]
(2) The torsion subgroups of $H^i_{\text{crys}}((X, M)/(\mathcal{E}, M_\mathcal{E}))$ and $H^i_{\text{crys}}((X, M)/W)$ have finite exponents for any $i \geq 0$.

**Proof.** (1) follows from Proposition A.3.1 (1) and the remark after (A.2.3). Since $\varprojlim_{n \geq 1} P_n$ is $p$-torsion free, the assertion (2) follows from the isomorphisms in Proposition A.3.1 (3). □

**Remark A.3.3** If $K$ is absolutely unramified, then we have

$$H^i_{\text{crys}}((X_n, M_n)/W_n) \simeq \mathbb{H}^i(Y, W_n \otimes \mathbb{F}_p),$$

which is finitely generated over $W_n$ by Theorem 8.8 (2) and (8.10.1) (see also [Hy2] (1.4.3), (2.4.2)). Consequently, the projective system $H^i_{\text{crys}}((X, M)/W)$ satisfies the Mittag-Leffler condition and we obtain a long exact sequence

$$\cdots \rightarrow H^i_{\text{crys}}((X, M)/W)_p \rightarrow H^i_{\text{crys}}((X, M)/(\mathcal{E}, M_\mathcal{E}))[p] \rightarrow H^{i+1}_{\text{crys}}((X, M)/W)_p \rightarrow \cdots,$$

which removes the assumption $(*$) in [La] p. 191. On the other hand, the author does not know if $H^i_{\text{crys}}((X, M)/W)$ satisfies the Mittag-Leffler condition even up to torsion, when $K$ is not absolutely unramified.

The following corollary has been used in the proof of Lemma 9.7 (1):

**Corollary A.3.4** In the following commutative diagram of canonical maps, the arrows (3) and (4) are injective:

$$
\begin{array}{ccc}
H^i_{\text{cont-cr}}((X, M)/W)_p & \xrightarrow{(1)} & H^i_{\text{crys}}((X, M)/(\mathcal{E}, M_\mathcal{E}))[p] \\
\downarrow (2) & & \downarrow (3) \\
H^i_{\text{crys}}((X, M)/W)_p & \xrightarrow{(4)} & H^i_{\text{crys}}((X, M)/(\mathcal{E}, M_\mathcal{E}))[p].
\end{array}
$$

In particular, the kernel of (1) agrees with that of (2).

**Proof.** The injectivity of (3) follows from Proposition A.3.1 (1) and (2) and the injectivity of the natural maps $R_{E_n} \rightarrow P_n$ for $n \geq 1$ ([Ts1] Proposition 4.1.5). The injectivity of (4) follows from Proposition A.3.1 (2) and (3). □

### A.4 Continuous-Galois crystalline cohomology

We define the continuous-Galois crystalline cohomology as follows:

$$H^i_{\text{cG-cr}}((X, M)/W) := R^i \left( \varprojlim_{n \geq 1} \Gamma_{\text{Gal}}(\overline{\mathbb{F}}_q) \right) \left( \mathcal{E}_{(X, M_n)} / W_n \right).$$
where $\overline{T}$ is as in (A.1.6), and $\Gamma_{\text{Gal}}$ denotes the functor taking $G_K$-invariant subgroups:

$$\Gamma_{\text{Gal}} := \Gamma(G_K, -) : \text{Mod}(G_K, \mathbb{Z}/p^*) \rightarrow \text{Mod}(\mathbb{Z}/p^*).$$

There is a natural map

$$H^i_{\text{cont-cris}}((X, M)/W) \rightarrow H^i_{\text{crys}}((X, M)/W) \quad (A.4.1)$$

by definition.

**Theorem A.4.2** There exists a Hochschild-Serre spectral sequence

$$E^2_{a,b} = H^a(K, H^b_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}) \Rightarrow H^{a+b}_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}.$$

**Proof.** Because $\overline{T}$ has an exact left adjoint functor, it preserves injectives and there exists a spectral sequence

$$E^2_{a,b} = H^a(K, H^b_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}) \Rightarrow H^{a+b}_{\text{crys}}((X, M)/W),$$

where $H^a(K, \{F_n\}_{n\geq 1})$ for a projective system $\{F_n\}_{n\geq 1}$ of discrete $G_K$-modules denotes the continuous Galois cohomology of $G_K$ in the sense of Jannsen [J] §2. We show that the canonical map

$$\alpha^{a,b} : H^a(K, H^b_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}) \rightarrow H^a(K, H^{b}_{\text{crys}}((X, M)/W))_{\mathbb{Q}_p}$$

(see the proof of loc. cit. Theorem 2.2) is bijective for $a, b \geq 0$. Put

$$L^b_n := \{p_n \otimes \mathbb{Z}_p \lim_{\leftarrow} L_n\} = B^+_{\text{st}} \otimes_{K_0} D^b_n,$$

$$T^b_n := H^b_{\text{crys}}((X, M)/W_n)$$

and $T^b := H^b_{\text{crys}}((X, M)/W)_{\mathbb{Q}_p}$.

Since the torsion part of $\lim_{\leftarrow} L^b_n$ has a finite exponent, the canonical map

$$\beta^{a,b} : H^a(K, L^b) \rightarrow H^a(K, L^b)_{\mathbb{Q}_p} \quad (A.4.3)$$

is bijective by loc. cit. Theorem 5.15 (c). We have a short exact sequence of objects in $\mathbb{Q} \otimes \text{Mod}(G_K, \mathbb{Z}/p^*)$

$$0 \rightarrow \mathbb{Q} \otimes (T^b_n) \rightarrow \mathbb{Q} \otimes (L^b_n) \rightarrow \mathbb{Q} \otimes (L^b) \rightarrow 0$$

and a short exact sequence of topological $G_K$-modules

$$0 \rightarrow T^b \rightarrow L^b \rightarrow L^b \rightarrow 0 \quad (A.4.4)$$

by Proposition A.3.1 (3) and [K4] Lemma 4.3. These exact sequences yield a commutative diagram with exact rows

$$\cdots \rightarrow H^{n-1}(K, L^b) \rightarrow H^n(K, T^b) \rightarrow H^n(K, L^b) \rightarrow H^n(K, L^b) \rightarrow \cdots$$

$$\downarrow \alpha^{n-1,b} \quad \downarrow \alpha^{n,b} \quad \downarrow \beta^{n-1,b} \quad \downarrow \beta^{n,b}$$

$$\cdots \rightarrow H^{n-1}(K, L^b)_{\mathbb{Q}_p} \rightarrow H^n(K, T^b_{\mathbb{Q}_p}) \rightarrow H^n(K, L^b)_{\mathbb{Q}_p} \rightarrow H^n(K, L^b)_{\mathbb{Q}_p} \rightarrow \cdots,$$

where the arrows $\beta^{n-1,b}$ and $\beta^{n,b}$ are bijective by (A.4.3). Hence the assertion follows from the five lemma. \qed
Corollary A.4.5 Put

\[ H^i_{\text{cont-cr}}((X, M)/W)^0_{Q_p} := \text{Ker}(H^i_{\text{cont-cr}}((X, M)/W)_{Q_p} \to H^{i+1}_{\text{crys}}((\mathcal{X}, \mathcal{M})/W)_{Q_p}). \]

Then the canonical homomorphism

\[ H^i_{\text{cont-cr}}((X, M)/W)^0_{Q_p} \to H^1(K, H^i_{\text{crys}}((\mathcal{X}, \mathcal{M})/W)_{Q_p}), \]

obtained from (A.4.1) and an edge homomorphism of the spectral sequence in Theorem A.4.2, fits into a commutative diagram

\[
\begin{array}{ccc}
H^i_{\text{crys}}((X, M)/(\mathcal{E}, M_\xi))_{Q_p} & \xrightarrow{\partial} & H^{i+1}_{\text{cont-cr}}((X, M)/W)^0_{Q_p} \\
\downarrow & & \downarrow \\
(B^+_{\text{st}} \otimes_{K_o} D^+)^{G_K} & \xrightarrow{(-1)^{i+1} \delta} & H^1(K, H^i_{\text{crys}}((\mathcal{X}, \mathcal{M})/W)_{Q_p}),
\end{array}
\]

where \( \partial \) is the connecting map induced by that in Proposition A.2.4 (see Corollary A.3.4 for the existence and the surjectivity), and \( \delta \) denotes the connecting map of continuous Galois cohomology associated with (A.4.4) with \( b = i \). The left vertical arrow is obtained from Proposition A.3.1 (2).

**Proof.** The assertion follows from Proposition A.3.1 (2) and a simple computation on boundary maps arising from the distinguished triangle

\[
\text{R}^T(E_{(\mathcal{X}, \mathcal{M})}/W) \xrightarrow{\text{can}} \text{R}^T(E_{(\mathcal{X}, \mathcal{M})}/(\mathcal{E}, M_\xi)) \\
\xrightarrow{\nu} \text{R}^T(E_{(\mathcal{X}, \mathcal{M})}/(\mathcal{E}, M_\xi)) \xrightarrow{\Phi^\wedge} \text{R}^T(E_{(\mathcal{X}, \mathcal{M})}/W)[1]
\]

in \( D^+(\text{Mod}(G_K, \mathbb{Z}/p^\bullet)) \) (a variant of Proposition A.2.4). The sign \((-1)^{i+1}\) in the diagram arises from the difference of the orientations between this distinguished triangle and (A.4.4), and the fact that the construction of connecting morphisms associated with short exact sequences of complexes commutes with the shift functor \([i]\) up to the sign \((-1)^i\). The details are straightforward and left to the reader. \( \square \)

### A.5 Syntomic complexes

We construct the following objects for \( r \geq 0 \):

\[
\mathcal{S}^\wedge(r)_{(X, M)} \in D^+(Y_{\text{et}}, \mathbb{Z}/p^\bullet) \quad \text{and} \quad \mathcal{S}^\wedge(r)_{(\mathcal{X}, \mathcal{M})} \in D^+(Y_{\text{et}}, G_K, \mathbb{Z}/p^\bullet),
\]

and the following objects for \( 0 \leq r \leq p - 1 \):

\[
\mathcal{S}(r)_{(X, M)} \in D^+(Y_{\text{et}}, \mathbb{Z}/p^\bullet) \quad \text{and} \quad \mathcal{S}(r)_{(\mathcal{X}, \mathcal{M})} \in D^+(Y_{\text{et}}, G_K, \mathbb{Z}/p^\bullet).
\]

**Definition A.5.1** Let \((T, M_T)\) be a log scheme over \( \mathbb{Z}_p \). A Frobenius endomorphism \( \varphi : (T, M_T) \to (T, M_T) \) is a morphism over \( \mathbb{Z}_p \) such that \( \varphi \otimes \mathbb{Z}/p : (T_1, M_{T_1}) \to (T_1, M_{T_1}) \) is the absolute Frobenius endomorphism in the sense of [K3] Definition 4.7.
To construct the objects $\mathcal{S}_r^\bullet (X, M)$ and $\mathcal{S}_r^\bullet (X, M)$, we fix an étale hypercovering $(X^*, M^*) \to (X, M)$ and a closed immersion $(X^*, M^*) \hookrightarrow (Z^*, M_{Z^*})$ of simplicial fine log schemes over $W$ such that $(Z^*, M_{Z^*})$ is smooth over $W$ and has a Frobenius endomorphism for each $i \in \mathbb{N}$. Let $n \geq 1$ be an integer, and let $(\mathcal{S}_n^*, M_{\mathcal{S}_n}^*)$ be the PD-envelope of $(X_n^*, M_n^*)$ in $(Z_n^*, M_{Z_n^*})$ with respect to the canonical PD-structure on $(p) \subset W_n$. For $i \geq 1$, let $\mathcal{J}^i \subset \mathcal{O}_{\mathcal{S}_n^*}$ be the $i$-th divided power of the ideal $\mathcal{J} = \text{Ker}(\mathcal{O}_{\mathcal{S}_n^*} \to \mathcal{O}_{X_n^*})$. For $i \leq 0$, put $\mathcal{J}^i := \mathcal{O}_{\mathcal{S}_n^*}$. Let $\mathcal{J}^{[r]}_{(X_n^*, M_n^*)}/W_n$ be the complex of sheaves on $Y_{et}^*$

$$\mathcal{J}^{[r]} \xrightarrow{d_i} \mathcal{J}^{[r-i]} \otimes_{\mathcal{O}_{Z_n^*}} \omega_{(Z_n^*, M_{Z_n^*})}/W_n \xrightarrow{d_1} \cdots \xrightarrow{d_i} \mathcal{J}^{[r-q]} \otimes_{\mathcal{O}_{Z_n^*}} \omega_{(Z_n^*, M_{Z_n^*})}/W_n \xrightarrow{d_1} \cdots ,$$

where $\mathcal{J}^{[r]}$ is placed in degree 0. See [Ts2] Corollary 1.10 for $d$. The complex $\mathcal{E}_{(X_n^*, M_n^*)}/W_n$ we considered in §A.1 agrees with $\mathcal{J}^{[r]}_{(X_n^*, M_n^*)}/W_n$. We define a complex $\mathcal{S}_n^\bullet (r)(X^*, M^*)$ on $Y_{et}^*$ as the mapping fiber of the homomorphism

$$p^r - \varphi_n^r : \mathcal{J}^{[r]}_{(X_n^*, M_n^*)} \to \mathcal{E}_{(X_n^*, M_n^*)}$$

For $0 \leq r \leq p - 1$, the Frobenius endomorphism on $(Z_{n+1}^*, M_{Z_{n+1}^*})$ induces a homomorphism of complexes

$$f_r := p^r - \varphi_{n+r}^r : \mathcal{J}^{[r]}_{(X_n^*, M_n^*)}/W_n \to \mathcal{E}_{(X_n^*, M_n^*)}/W_n$$

(cf. [Ts2] p. 540). We define a complex $\mathcal{S}_n^\bullet (r)(X^*, M^*)$ on $Y^*_{et}$ as the mapping fiber of the homomorphism

$$1 - f_r : \mathcal{J}^{[r]}_{(X_n^*, M_n^*)} \to \mathcal{E}_{(X_n^*, M_n^*)}$$

Regarding $\mathcal{S}_n^\bullet (r)(X^*, M^*)$ and $\mathcal{S}_n^\bullet (r)(X^*, M^*)$ as complexes of projective systems (on $n \geq 1$) of sheaves on $Y_{et}^*$, we define

$$\mathcal{S}_r^\bullet (X, M) := R\theta_*(\mathcal{S}_r^\bullet (r)(X^*, M^*)) \quad (r \geq 0),$$

$$\mathcal{S}_r^\bullet (X, M) := R\theta_*(\mathcal{S}_r^\bullet (r)(X^*, M^*)) \quad (0 \leq r \leq p - 1),$$

where $\theta : \text{Shv}(Y_{et}^*, \mathbb{Z}/p^*) \to \text{Shv}(Y_{et}^*, \mathbb{Z}/p^*)$ denotes the natural morphism of topoi. The resulting objects are independent of the pair $((X^*, M^*), (Z^*, M_{Z^*}))$ (cf. [K2] p. 212).

We construct $\mathcal{S}_r^\bullet (r)(X_{\mathcal{S}_n^*})$ for $r \geq 0$ and $\mathcal{S}_r^\bullet (r)(X_{\mathcal{S}_n^*})$ for $0 \leq r \leq p - 1$ as follows. Fix an étale hypercovering $(X^*, M^*) \to (X, M)$ and for each finite extension $L/K$ contained in $\mathcal{R}$, fix a closed immersion $(X_{O_L^*, M_{O_L}}^*) \hookrightarrow (Z_{L}^*, M_{Z_L^*})$ of simplicial fine log schemes over $W$ such that $(Z_L^*, M_{Z_L^*})$ is smooth over $W$ for each $i \in \mathbb{N}$ and $L/K$, such that $Z_L^*$ has a Frobenius endomorphism for each $i \in \mathbb{N}$ and $L/K$, and such that for finite extensions $L'/L$ there are morphisms $\tau_{L'/L} : (Z_{L^*}, M_{Z_{L}}) \to (Z_{L'}^*, M_{Z_{L}^*})$ which satisfy transitivity and compatibility with Frobenius morphisms. For a finite extension $L/K$, we define $Y^*_{L}$ in a similar way as in §A.1. We define complexes
which satisfy

\[ \text{Let } a \text{ with } a \in \mathbb{Z} \text{ satisfy} \]

\( \text{For } \theta \in \mathbb{Z}, \text{ we define} \)

\[ \text{Theorem A.5.6 ([Ts1] \S 3.1, [K4] Theorem 5.4) For } r \geq 0, \text{ there exists a} \]

\[ \text{compatible with product structures} \]

\[ \text{If } r \leq p - 2, \text{ then } \eta^*_r \text{ factors through an isomorphism} \]

\[ \text{Documenta Mathematica 18 (2013) 177–247} \]
Proof. We define \( \eta^*_p \) applying the arguments in [Ts1] §3.1 in the category of \( \mathbb{Z}/p^\bullet \)-sheaves. If \( r \leq p - 2 \), then we have \( \mathbb{Z}/p^\bullet(r)^* = \mu_{p^r}^\infty \) and \( \eta^*_p \) factors through a morphism \( \eta^*_p : \mathcal{A}(r)(\mathcal{X}, \mathcal{M}) \to \mathcal{T} H^\infty_{\text{cont}} \mu_{p^r}^\infty \) by the construction of \( \eta^*_p \) (loc. cit. (3.1.11)). The morphism \( \eta^*_p \) induces an isomorphism as claimed, because \( \mathcal{A}(r)(\mathcal{X}, \mathcal{M}) \) is concentrated in \([0, r]\) and \( \eta^*_p \) induces isomorphisms on the \( q \)-th cohomology objects with \( 0 \leq q \leq r \) by [K4] Theorem 5.4.

We define

\[
H^i_{\text{syn}}((X, M), \mathcal{A}(r)) := R^i \Gamma(\mathcal{A}(r)(X, M)), \\
H^i_{\text{syn}}((X, M), \mathcal{Z}_p(r)) := \varprojlim H^i_{\text{syn}}((X, M), \mathcal{A}(r)), \\
H^i_{\text{syn}}((X, M), \mathcal{F}_p(r)) := Q_p \otimes \mathbb{Z}_p H^i_{\text{syn}}((X, M), \mathcal{A}(r)), \\
H^i_{\text{syn}}((X, M), \mathcal{F}_p(r)) := Q_p \otimes \mathbb{Z}_p \varprojlim R^i \mathcal{T}(\mathcal{A}(r)(\mathcal{X}, \mathcal{M})).
\]

where \( \Gamma \) and \( \mathcal{T} \) are as in (A.1.5) and (A.1.6), respectively.

A.6 CONTINUOUS(-GAOIS) SYNTOMIC COHOMOLOGY

We assume \( r \leq p - 2 \) in what follows. For \( i \geq 0 \), we define the continuous syntomic cohomology as follows:

\[
H^i_{\text{cont-syn}}((X, M), \mathcal{Z}_p(r)) := R^i \left( \varprojlim \Gamma \right) (\mathcal{A}(r)(X, M)).
\]

Similarly, we define the continuous-Galois syntomic cohomology as follows:

\[
H^i_{\text{G-cont-syn}}((X, M), \mathcal{F}_p(r)) := R^i \left( \varprojlim \Gamma_{\text{Gal}} \right) (\mathcal{A}(r)(\mathcal{X}, \mathcal{M})).
\]

We put

\[
H^i_{\text{cont-syn}}((X, M), \mathcal{F}_p(r)) := Q_p \otimes \mathbb{Z}_p H^i_{\text{cont-syn}}((X, M), \mathcal{Z}_p(r)).
\]

PROPOSITION A.6.1 Let \( i \geq 0 \) be an integer.

1. Let \( \eta : H^i_{\text{syn}}((X, M), \mathcal{F}_p(r)) \to H^i(X, M, \mathcal{A}(r)) \) be as in Lemma 9.5. Then the kernel of the composite map

\[
H^i_{\text{cont-syn}}((X, M), \mathcal{F}_p(r)) \to H^i_{\text{syn}}((X, M), \mathcal{F}_p(r)) \xrightarrow{\eta} H^i(X, M, \mathcal{A}(r))
\]

agrees with that of the composite map

\[
H^i_{\text{cont-syn}}((X, M), \mathcal{F}_p(r)) \to H^i_{\text{syn}}((X, M), \mathcal{F}_p(r)) \to H^i_{\text{crys}}((X, \mathcal{M})/W)_{\mathbb{Q}_p},
\]

which we denote by \( H^i_{\text{cont-syn}}((X, M), \mathcal{F}_p(r))^{(0)} \), in what follows.

2. If \( K \) is a \( p \)-adic local field (i.e., \( k \) is finite), then we have

\[
H^i_{\text{cont-syn}}((X, M), \mathcal{Z}_p(r)) \xrightarrow{\sim} H^i_{\text{syn}}((X, M), \mathcal{Z}_p(r)).
\]

In particular, we have the following canonical map in this case:

\[
H^i_{\text{syn}}((X, M), \mathcal{Z}_p(r)) \to H^i_{\text{cont-cr}}((X, M)/W).
\]
(3) If \( r \geq d := \dim(X_K) \), then we have
\[
H_\text{crys}^{i}( (X, M) , \mathcal{Z}_p(r) ) \rightarrow H_{\text{cont}}^{i}(X_K, \mathbb{Z}_p(r)),
\]
where \( H_{\text{cont}}^{*}(X_K, \mathbb{Z}_p(r)) \) denotes the continuous étale cohomology \([J]\).

**Proof.** (1) The assertion immediately follows from Lemma 9.5.
(2) There is a short exact sequence analogous to (A.2.3)
\[
0 \rightarrow R^{1}\lim_{\rightarrow} H_{\text{syn}}^{i-1}( (X, M), \mathcal{Z}_p(r) ) \rightarrow H_{\text{cont}}^{i}( (X, M), \mathcal{Z}_p(r) ) \rightarrow H_{\text{syn}}^{i}( (X, M), \mathcal{Z}_p(r) ) \rightarrow 0.
\]
Since \( X \) is proper over \( k \) and \( k \) is finite by assumption, \( H_{\text{syn}}^{i-1}( (X, M), \mathcal{Z}_p(r) ) \) is finite for any \( i \), \( n \geq 1 \) by \([Ts1]\) Proposition 2.4.1. See also the remark in loc. cit., p. 263. The assertion follows from these facts.
(3) Since \( r \geq d \) by assumption, (A.5.7) implies \( \mathcal{Z}_p(r) \simeq \mathcal{T}' R_{\gamma}^{*} \mu_p^{\otimes r} \). Hence the assertion follows from the isomorphisms in \( D^{+}(\text{Mod}(G_{K-\mathbb{Z}/p}) \big) \)
\[
R\Gamma(X_{\mathbb{F}}, \mu_p^{\otimes r}) = R\Gamma(X, R_{\gamma}^{*} \mu_p^{\otimes r}) \rightarrow R\Gamma(Y, \tau^{*} R_{\gamma}^{*} \mu_p^{\otimes r}), \quad \text{(A.6.2)}
\]
where the last isomorphism is a consequence of the proper base-change theorem for the usual étale cohomology. \( \square \)

For \( i \geq 0 \), put
\[
H_{\text{syn}}^{i}( (X, M), \mathcal{Z}_p(r) ) := \text{Ker}(\eta : H_{\text{syn}}^{i}( (X, M), \mathcal{Z}_p(r) ) \rightarrow H_{\text{syn}}^{i}(X_K, \mathbb{Z}_p(r))),
\]
\[
H_{\text{cont}}^{i}( (X, M), \mathcal{Z}_p(r) ) := \text{Ker}(\eta : H_{\text{cont}}^{i}( (X, M), \mathcal{Z}_p(r) ) \rightarrow H_{\text{cont}}^{i}(X_K, \mathbb{Z}_p(r))).
\]
We have \( H_{\text{cont}}^{i}(X_K, \mathbb{Z}_p(r)) = H_{\text{cont}}^{i}(X_K, \mathbb{Q}_p(r)) \) when \( K \) is a \( p \)-adic local field. The following corollary is a consequence of Proposition A.6.1 (1), (2) and the covariant functoriality of Hochschild-Serre spectral sequences in coefficients (see also the diagram in the proof of Theorem A.6.7 below).

**Corollary A.6.3** Assume that \( K \) is a \( p \)-adic local field, and let \( e \) be the composite map
\[
e : H_{\text{syn}}^{i+1}( (X, M), \mathcal{Z}_p(r) ) \rightarrow H_{\text{cont}}^{i+1}(X_K, \mathbb{Q}_p(r)) \rightarrow H^{i}(K, H^{1}(X_{\mathbb{F}}, \mathbb{Q}_p(r))),
\]
where the last map is an edge homomorphism of the Hochschild-Serre spectral sequence (9.0.1). If \( r \geq d \), then \( e \) fits into a commutative diagram
\[
\begin{array}{ccc}
H_{\text{syn}}^{i+1}( (X, M), \mathcal{Z}_p(r) ) & \rightarrow & H_{\text{cont}}^{i+1}( (X, M)/W)_{\mathbb{Q}_p} \\
\downarrow e & & \downarrow \beta^{i,r} \\
H^{i}(K, H^{1}(X_{\mathbb{F}}, \mathbb{Q}_p(r))) & \rightarrow & H^{i}(K, H_{\text{syn}}^{1}(X_{\mathbb{F}}, (X, M)/W)_{\mathbb{Q}_p}),
\end{array}
\]
where the top arrow is obtained from Proposition A.6.1 (1) and (2), the right vertical arrow is the map in Corollary A.4.5 and \( \beta^{i,r} \) is as in the proof of Theorem 9.9.
We next construct a commutative diagram in $\mathbb{Q} \otimes D^+(\text{Mod}(G_K, \mathbb{Z}/p^\bullet))$ assuming $r < d$

$$
\begin{array}{ccc}
\mathbb{Q} \otimes R\Gamma(\overline{Y}, \mathcal{A}_r(r)(\overline{X_\bullet \mathcal{M}_\bullet})) & \xrightarrow{f^r} & \mathbb{Q} \otimes R\Gamma(X_{\overline{\Gamma}}, \mu^{\overline{\bullet}}) \\
\downarrow & & \downarrow g^r \\
\mathbb{Q} \otimes R\Gamma(X_{\overline{\Gamma}}, \mu^{\overline{\bullet}}) & \xrightarrow{h^r} & \mathbb{Q} \otimes (R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) \otimes \mathbb{Z}/p^*(r-d)'),
\end{array}
$$

which is a key ingredient of the commutative diagram (A) of §9 for the case $r < d$. See (A.5.5) for the isomorphism (1) and the product of crystalline complexes. We define $h^r$ as the composite morphism

$$
\begin{align*}
\mathbb{Q} \otimes R\Gamma(\overline{Y}, \mathcal{A}_r(r)(\overline{X_\bullet \mathcal{M}_\bullet})) & \xrightarrow{(A.5.3)} \mathbb{Q} \otimes R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) \\
\mathbb{Q} \otimes R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) & \xrightarrow{(A.5.2)} \mathbb{Q} \otimes \{ R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) \otimes \mathbb{Z}/p^*(d-r') \otimes \mathbb{Z}/p^*(r-d') \} \\
\mathbb{Q} \otimes \{ R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) \otimes \mathbb{Z}/p^*(d-r') \otimes \mathbb{Z}/p^*(r-d') \} & \rightarrow \mathbb{Q} \otimes \{ R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet}) \otimes \mathbb{Z}/p^*(r-d') \}.
\end{align*}
$$

where the last arrow is induced by the $p^{d-r}$-times of the composite map

$$
\begin{align*}
\mathbb{Q} \otimes \mathbb{Z}/p^*(d-r') & \xrightarrow{(1)} \mathbb{Q} \otimes H^0_{\text{syn}}((\overline{X_\bullet \mathcal{M}_\bullet}), \mathcal{A}_r(d-r)) \\
\mathbb{Q} \otimes H^0_{\text{syn}}((\overline{X_\bullet \mathcal{M}_\bullet}), \mathcal{A}_r(d-r)) & \xrightarrow{(A.5.2)} \mathbb{Q} \otimes H^0_{\text{crys}}((\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet)
\end{align*}
$$

(see (A.6.6) below for the isomorphism (1)) and the product of crystalline complexes. We define $f^r$ as the morphism induced by (A.5.7) and the isomorphisms in (A.6.2). To define $g^r$, we need an isomorphism

$$
\tilde{j}^d : \mathbb{Q} \otimes R\Gamma(\overline{Y}, \mathcal{A}_r(d)(\overline{X_\bullet \mathcal{M}_\bullet})) \simeq \mathbb{Q} \otimes R\Gamma(X_{\overline{\Gamma}}, \mathbb{Z}/p^*(d'))
$$

induced by $\tilde{n}_d^\circ$ in Theorem A.5.6 (cf. [Ts1] Theorem 3.3.2 (1)). We define

$$
\tilde{h}^d : \mathbb{Q} \otimes R\Gamma(\overline{Y}, \mathcal{A}_r(d)(\overline{X_\bullet \mathcal{M}_\bullet})) \rightarrow \mathbb{Q} \otimes R\Gamma(\overline{Y}, E_{(\overline{X_\bullet \mathcal{M}_\bullet})/W_\bullet})
$$

in the same way as $h^r$ (using (A.5.2) instead of (A.5.3)) and define $g^d := p^d \cdot (\tilde{h}^d \circ (\tilde{j}^d)^{-1})$. Finally we define $g^r$ as the composite of the natural map

$$
R\Gamma(X_{\overline{\Gamma}}, \mu^{\overline{\bullet}}) \rightarrow R\Gamma(X_{\overline{\Gamma}}, \mathbb{Z}/p^*(d')) \otimes \mathbb{Z}/p^*(r-d')
$$

and $g^d \circ \text{id}$. The above diagram is commutative by the definition of $g^r$ and the compatibility of $\eta_\delta^\circ$ with products (cf. [Ts1] §3.1). Now we prove

**Theorem A.6.7** Assume that $K$ is a $p$-adic local field (i.e., $k$ is finite). Then the diagram (9.9.2) commutes for $r < d$. 

*Documenta Mathematica* 18 (2013) 177–247
Proof. We first note the isomorphisms

\[ H^{i+1}_{\text{cont-syn}}((X, M), \mathcal{F}_{p^*}(r)) \xrightarrow{\sim} H^{i+1}_{\text{syn}}((X, M), \mathcal{F}_{p^*}(r)), \]
\[ H^{i+1}_{\text{cont}}(X_K, \mathbb{Q}_p(r)) \xrightarrow{\sim} H^{i+1}(X_K, \mathbb{Q}_p(r)) \]

by the assumption that \( k \) is finite (cf. Proposition A.6.1 (2)). For integers \( m \geq 0 \) and \( s < 0 \), put

\[ H^m_{\text{crys}}((X, M)/W; s) := R^m(\lim_{\to} \Gamma_{g_0}) \{ RF(\mathcal{Y}, \mathbb{Z}/p^{s+1}) \otimes \mathbb{Z}/p^s(s') \}, \]
\[ H^m_{\text{crys}}((X, M)/W; s)_{\mathbb{Q}_p} := \text{Ker}(H^m_{\text{crys}}((X, M)/W; s)_{\mathbb{Q}_p} \to H^m_{\text{crys}}((X, \bar{M})/W)_{\mathbb{Q}_p}(s)). \]

By (A.6.4), there is a commutative diagram

\[
\begin{array}{ccc}
H^{i+1}_{\text{syn}}((\bar{X}, \bar{M}), \mathcal{F}_{p^*}(r)) & \xrightarrow{f^*} & H^{i+1}(X_{\mathbb{Q}_p}(r))_{\mathbb{Q}_p} \\
\downarrow{h^*} & & \downarrow{g^*} \\
H^{i+1}(X_{K'}, \mathbb{Q}_p(r))_{\mathbb{Q}_p} & \xrightarrow{\gamma^*} & H^{i+1}_{\text{cont}}((X, \bar{M})/W)_{\mathbb{Q}_p}(r - d),
\end{array}
\]

where the bottom arrow is the same as \( \beta^{i+1,r} \). By this diagram we obtain the arrows \((g^*)^0\) and \((h^*)^0\) in the following commutative diagram:

\[
\begin{array}{ccc}
H^{i+1}_{\text{syn}}((X, M), \mathcal{F}_{p^*}(r))^0 & \xrightarrow{(f^*)^0} & H^{i+1}_{\text{cont}}(X, \mathbb{Q}_p(r))^0 \\
\downarrow{(h^*)^0} & & \downarrow{(g^*)^0} \\
H^{i+1}(X_{K'}, \mathbb{Q}_p(r))^0 & \xrightarrow{\gamma^*} & H^{i+1}_{\text{crys}}((X, \bar{M})/W; r - d)^0_{\mathbb{Q}_p} \\
\downarrow{\text{edge}} & & \downarrow{\text{edge}} \\
H^1(K, H^i(X_{\mathbb{Q}_p}, \mathbb{Z}/p^*)_{\mathbb{Q}_p}) & \xrightarrow{g^*} & H^1(K, H^i_{\text{crys}}((\bar{X}, \bar{M})/W; r - d))^0_{\mathbb{Q}_p} \\
\downarrow{\text{edge}} & & \downarrow{\text{edge}} \\
H^1(K, H^i(X_{\mathbb{Q}_p}, \mathbb{Q}_p(r))) & \xrightarrow{\beta^i,r} & H^1(K, H^i_{\text{crys}}((\bar{X}, \bar{M})/W)_{\mathbb{Q}_p}(r - d)),
\end{array}
\]

where the top triangle is induced by (A.6.4) and the central square commutes by the functoriality of Hochschild-Serre spectral sequences. The arrows \( c \) and \( c' \) are canonical maps, and the bottom square commutes by the definitions of \( \beta^{i,r} \) and \( g^* \). The map \( c \) is bijective by [J] Theorem 5.15 (c) and the finiteness of \( H^i(X_{\mathbb{Q}_p}, \mathbb{Z}/p^*) \) for \( n \geq 1 \). The bijectivity of \( c' \) is obtained from a similar argument as for the proof of Theorem A.4.2. Moreover it is easy to see that the composite of the left column agrees with the left vertical arrow of (9.9.2), and that the composite of \( h^* \) and the right column agrees with \( \gamma^{i,r} \) in (9.9.2). The commutativity in question follows from these facts. \( \square \)

Factorial Cluster Algebras

Christof Geiß, Bernard Leclerc, and Jan Schröer

Received: October 13, 2011
Communicated by Edward Frenkel

Abstract. We show that cluster algebras do not contain non-trivial units and that all cluster variables are irreducible elements. Both statements follow from Fomin and Zelevinsky’s Laurent phenomenon. As an application we give a criterion for a cluster algebra to be a factorial algebra. This can be used to construct cluster algebras, which are isomorphic to polynomial rings. We also study various kinds of upper bounds for cluster algebras, and we prove that factorial cluster algebras coincide with their upper bounds.

1. Introduction and main results

1.1. Introduction. The introduction of cluster algebras by Fomin and Zelevinsky \cite{FZ1} triggered an extensive theory. Most results deal with the combinatorics of seed and quiver mutations, with various categorifications of cluster algebras, and with cluster phenomena occurring in various areas of mathematics, like representation theory of finite-dimensional algebras, quantum groups and Lie theory, Calabi-Yau categories, non-commutative Donaldson-Thomas invariants, Poisson geometry, discrete dynamical systems and algebraic combinatorics.

On the other hand, there are not many results on cluster algebras themselves. As a subalgebra of a field, any cluster algebra $A$ is obviously an integral domain. It is also easy to show that its field of fractions $\text{Frac}(A)$ is isomorphic to a field $K(x_1, \ldots, x_m)$ of rational functions. Several classes of cluster algebras are known to be finitely generated, e.g. acyclic cluster algebras \cite[Corollary 1.21]{BFZ} and also a class of cluster algebras arising from Lie theory \cite[Theorem 3.2]{GLS2}. Berenstein, Fomin and Zelevinsky gave an example of a cluster algebra which is not finitely generated. (One applies \cite[Theorem 1.24]{BFZ} to the example mentioned in \cite[Proposition 1.26]{BFZ}.) Only very little is known on further ring theoretic properties of an arbitrary cluster algebra $A$. Here are some basic questions we would like to address:

- Which elements in $A$ are invertible, irreducible or prime?
- When is $A$ a factorial ring?
- When is $A$ a polynomial ring?

In this paper, we work with cluster algebras of geometric type.

1.2. Definition of a cluster algebra. In this section we repeat Fomin and Zelevinsky’s definition of a cluster algebra.

A matrix $A = (a_{ij}) \in M_{n,n}(\mathbb{Z})$ is skew-symmetrizable (resp. symmetrizable) if there exists a diagonal matrix $D = \text{Diag}(d_1, \ldots, d_n) \in M_{n,n}(\mathbb{Z})$ with positive diagonal entries $d_1, \ldots, d_n$ such that $DA$ is skew-symmetric (resp. symmetric), i.e. $d_ia_{ij} = -d_ja_{ji}$ (resp. $d_ia_{ij} = d_ja_{ji}$) for all $i, j$.

Let $m, n$ and $p$ be integers with

$$m \geq p \geq n \geq 1 \quad \text{and} \quad m > 1.$$ 

Let $B = (b_{ij}) \in M_{m,n}(\mathbb{Z})$ be an $(m \times n)$-matrix with integer entries. By $B^\circ \in M_{n,n}(\mathbb{Z})$ we denote the principal part of $B$, which is obtained from $B$ by deleting the last $m - n$ rows.

Let $\Delta(B)$ be the graph with vertices $1, \ldots, m$ and an edge between $i$ and $j$ provided $b_{ij}$ or $b_{ji}$ is non-zero. We call $B$ connected if the graph $\Delta(B)$ is connected.
Throughout, we assume that $K$ is a field of characteristic 0 or $K = \mathbb{Z}$. Let $\mathcal{F} := K(X_1, \ldots, X_m)$ be the field of rational functions in $m$ variables.

A **seed** of $\mathcal{F}$ is a pair $(x, B)$ such that the following hold:

(i) $B \in M_{m,n}(\mathbb{Z})$,
(ii) $B$ is connected,
(iii) $B^\circ$ is skew-symmetrizable,
(iv) $x = (x_1, \ldots, x_m)$ is an $m$-tuple of elements in $\mathcal{F}$ such that $x_1, \ldots, x_m$ are algebraically independent over $K$.

For a seed $(x, B)$, the matrix $B$ is the **exchange matrix** of $(x, B)$. We say that $B$ has **maximal rank** if $\text{rank}(B) = n$.

Given a seed $(x, B)$ and some $1 \leq k \leq n$ we define the **mutation** of $(x, B)$ at $k$ as

$$
\mu_k(x, B) := (x', B'),
$$

where $B' = (b'_{ij})$ is defined as

$$
b'_{ij} := \begin{cases} 
-b_{ij} & \text{if } i = k \text{ or } j = k, \\
b_{ij} + \frac{|b_{ik}|b_{kj} + b_{ik}|b_{kj}|}{2} & \text{otherwise}, 
\end{cases}
$$

and $x' = (x'_1, \ldots, x'_m)$ is defined as

$$
x'_s := \begin{cases} 
x_k^{-1} \prod_{b_{ik} > 0} x_{ki}^{b_{ik}} + x_k^{-1} \prod_{b_{ik} < 0} x_{ki}^{-b_{ik}} & \text{if } s = k, \\
x_s & \text{otherwise}. 
\end{cases}
$$

The equality

$$
x_kx'_k = \prod_{b_{ik} > 0} x_{ki}^{b_{ik}} + \prod_{b_{ik} < 0} x_{ki}^{-b_{ik}}
$$

is called an **exchange relation**. We write

$$
\mu(x, B)(x_k) := x'_k
$$

and

$$
\mu_k(B) := B'.
$$

It is easy to check that $(x', B')$ is again a seed. Furthermore, we have $\mu_k\mu_k(x, B) = (x, B)$.

Two seeds $(x, B)$ and $(y, C)$ are **mutation equivalent** if there exists a sequence $(i_1, \ldots, i_t)$ with $1 \leq i_j \leq n$ for all $j$ such that

$$
\mu_{i_t} \cdots \mu_{i_2} \mu_{i_1}(x, B) = (y, C).
$$

In this case, we write $(y, C) \sim (x, B)$. This yields an equivalence relation on all seeds of $\mathcal{F}$. (By definition $(x, B)$ is also mutation equivalent to itself.)

For a seed $(x, B)$ of $\mathcal{F}$ let

$$
\mathcal{X}(x, B) := \bigcup_{(y, C) \sim (x, B)} \{y_1, \ldots, y_n\},
$$

**Factorial Cluster Algebras**

251

Documenta Mathematica 18 (2013) 249–274
where the union is over all seeds \((y, C)\) with \((y, C) \sim (x, B)\). By definition, the cluster algebra \(A(x, B)\) associated to \((x, B)\) is the \(L\)-subalgebra of \(F\) generated by \(X_{(x,B)}\), where

\[
L := K[x_{n+1}^{\pm 1}, \ldots, x_p^{\pm 1}, x_{p+1}, \ldots, x_m]
\]

is the localization of the polynomial ring \(K[x_{n+1}, \ldots, x_m]\) at \(x_{n+1} \cdots x_p\). (For \(p = n\) we set \(x_{n+1} \cdots x_p := 1\).) Thus \(A(x, B)\) is the \(K\)-subalgebra of \(F\) generated by

\[
\{x_{n+1}^{\pm 1}, \ldots, x_p^{\pm 1}, x_{p+1}, \ldots, x_m\} \cup X_{(x,B)}.
\]

The elements of \(X_{(x,B)}\) are the cluster variables of \(A(x, B)\).

We call \((y, C)\) a seed of \(A(x, B)\) if \((y, C) \sim (x, B)\). In this case, for any \(1 \leq k \leq n\) we call \((y_k, \mu_{(y,C)}(y_k))\) an exchange pair of \(A(x, B)\). Furthermore, the \(m\)-tuple \(y\) is a cluster of \(A(x, B)\), and monomials of the form \(y_1^{a_1} y_2^{a_2} \cdots y_m^{a_m}\) with \(a_i \geq 0\) for all \(i\) are called cluster monomials of \(A(x, B)\).

Note that for any cluster \(y\) of \(A(x, B)\) we have \(y_i = x_i\) for all \(n + 1 \leq i \leq m\). These \(m - n\) elements are the coefficients of \(A(x, B)\). There are no invertible coefficients if \(p = n\).

Clearly, for any two seeds of the form \((x, B)\) and \((y, B)\), there is an algebra isomorphism \(\eta: A(x, B) \to A(y, B)\) with \(\eta(x_i) = y_i\) for all \(1 \leq i \leq m\), which respects the exchange relations. Furthermore, if \((x, B)\) and \((y, C)\) are mutation equivalent seeds, then \(A(x, B) = A(y, C)\) and we have \(K(x_1, \ldots, x_m) = K(y_1, \ldots, y_m)\).

1.3. TRIVIAL CLUSTER ALGEBRAS AND CONNECTEDNESS OF EXCHANGE MATRICES. Note that we always assume \(m > 1\). For \(m = 1\) we would get the trivial cluster algebra \(A(x, B)\) with exactly two cluster variables, namely \(x_1\) and \(x_1' := \mu_{(x,B)}(x_1) = x_1^{-1}(1 + 1)\). In particular, for \(K \neq \mathbb{Z}\), both cluster variables are invertible in \(A(x, B)\), and \(A(x, B)\) is just the Laurent polynomial ring \(K[x_1^{\pm 1}]\).

Furthermore, for any seed \((x, B)\) of \(F\) the exchange matrix \(B\) is by definition connected. For non-connected \(B\) one could write \(A(x, B)\) as a product \(A(x_1, B_1) \times A(x_2, B_2)\) of smaller cluster algebras and study the factors \(A(x_i, B_i)\) separately. The connectedness assumption also ensures that there are no exchange relations of the form \(x_1 x_1' = 1 + 1\).

1.4. THE LAURENT PHENOMENON. It follows by induction from the exchange relations that for any cluster \(y\) of \(A(x, B)\), any cluster variable \(z\) of \(A(x, B)\) is of the form

\[
z = \frac{f}{g},
\]

where \(f, g \in \mathbb{N}[y_1, \ldots, y_m]\) are integer polynomials in the cluster variables \(y_1, \ldots, y_m\) with non-negative coefficients. For any seed \((x, B)\) of \(F\) let

\[
\mathcal{L}_x := K[x_1^{\pm 1}, \ldots, x_n^{\pm 1}, x_{n+1}^{\pm 1}, \ldots, x_p^{\pm 1}, x_{p+1}, \ldots, x_m]
\]
be the localization of $K[x_1,\ldots,x_m]$ at $x_1 x_2 \cdots x_p$, and let

$$\mathcal{L}_{x, Z} := \mathbb{Z}[x_1^{\pm 1}, \ldots, x_n^{\pm 1}, x_{n+1}, \ldots, x_m]$$

be the localization of $\mathbb{Z}[x_1,\ldots,x_m]$ at $x_1 x_2 \cdots x_n$. We consider $\mathcal{L}_x$ and $\mathcal{L}_{x,Z}$ as subrings of the field $F$. The following remarkable result, known as the \textit{Laurent phenomenon}, is due to Fomin and Zelevinsky and is our key tool to derive some ring theoretic properties of cluster algebras.

\textbf{Theorem 1.1} ([FZ1, Theorem 3.1], [FZ2, Proposition 11.2]). For each seed $(x, B)$ of $F$ we have

$$A(x, B) \subseteq \overline{A}(x, B) := \bigcap_{(y, C) \sim (x, B)} \mathcal{L}_y$$

and

$$X(x, B) \subset \bigcap_{(y, C) \sim (x, B)} \mathcal{L}_{y,Z}.$$ 

The algebra $\overline{A}(x, B)$ is called the \textit{upper cluster algebra} associated to $(x, B)$, compare [BFZ, Section 1].

1.5. Upper bounds. For a seed $(x, B)$ and $1 \leq k \leq n$ let $(x_k, B_k) := \mu_k(x, B)$. Berenstein, Fomin and Zelevinsky [BFZ] called

$$U(x, B) := \mathcal{L}_x \cap \bigcap_{k=1}^n \mathcal{L}_{x_k}$$

the \textit{upper bound} of $A(x, B)$. They prove the following:

\textbf{Theorem 1.2} ([BFZ, Corollary 1.9]). Let $(x, B)$ and $(y, C)$ be mutation equivalent seeds of $F$. If $B$ has maximal rank and $p = m$, then $U(x, B) = U(y, C)$. In particular, we have $\overline{A}(x, B) = U(x, B)$.

For clusters $y$ and $z$ of $A(x, B)$ define

$$U(y, z) := \mathcal{L}_y \cap \mathcal{L}_z.$$ 

1.6. Acyclic cluster algebras. Let $(x, B)$ be a seed of $F$ with $B = (b_{ij})$. Let $\Sigma(B)$ be the quiver with vertices $1,\ldots,n$, and arrows $i \to j$ for all $1 \leq i, j \leq n$ with $b_{ij} > 0$, compare [BFZ, Section 1.4]. So $\Sigma(B)$ encodes the sign-pattern of the principal part $B^\circ$ of $B$.

The seed $(x, B)$ and $B$ are called acyclic if $\Sigma(B)$ does not contain any oriented cycle. The cluster algebra $A(x, B)$ is \textit{acyclic} if there exists an acyclic seed $(y, C)$ with $(y, C) \sim (x, B)$.
1.7. Skew-symmetric exchange matrices and quivers. Let $B = (b_{ij})$ be a matrix in $M_{m,n}(\mathbb{Z})$ such that $B^\tau$ is skew-symmetric. Let $\Gamma(B)$ be the quiver with vertices 1, ..., $m$ and $b_{ij}$ arrows $i \rightarrow j$ if $b_{ij} > 0$, and $-b_{ij}$ arrows $j \rightarrow i$ if $b_{ij} < 0$. Thus given $\Gamma(B)$, we can recover $B$. In the skew-symmetric case one often works with quivers and their mutations instead of exchange matrices.

1.8. Main results. For a ring $R$ with 1, let $R^\times$ be the set of invertible elements in $R$. Non-zero rings without zero divisors are called integral domains. A non-invertible element $a$ in an integral domain $R$ is irreducible if it cannot be written as a product $a = bc$ with $b, c \in R$ both non-invertible. Cluster algebras are integral domains, since they are by definition subrings of fields.

Theorem 1.3. For any seed $(x, B)$ of $\mathcal{F}$ the following hold:

(i) We have $A(x, B) = \{ \lambda x_{n+1}^{a_{n+1}} \cdots x_p^{a_p} \mid \lambda \in K^\times, a_i \in \mathbb{Z} \}$.

(ii) Any cluster variable in $A(x, B)$ is irreducible.

For elements $a, b$ in an integral domain $R$ we write $a | b$ if there exists some $c \in R$ with $b = ac$. A non-invertible element $a$ in a commutative ring $R$ is prime if whenever $a | bc$ for some $b, c \in R$, then $a | b$ or $a | c$. Every prime element is irreducible, but the converse is not true in general. Non-zero elements $a, b \in R$ are associate if there is some unit $c \in R^\times$ with $a = bc$. An integral domain $R$ is factorial if the following hold:

(i) Every non-zero non-invertible element $r \in R$ can be written as a product $r = a_1 \cdots a_s$ of irreducible elements $a_i \in R$.

(ii) If $a_1 \cdots a_s = b_1 \cdots b_t$ with $a_i, b_j \in R$ irreducible for all $i$ and $j$, then $s = t$ and there is a bijection $\pi: \{1, \ldots, s\} \rightarrow \{1, \ldots, t\}$ such that $a_i$ and $b_{\pi(i)}$ are associate for all $1 \leq i \leq s$.

For example, any polynomial ring is factorial. In a factorial ring, all irreducible elements are prime.

Two clusters $y$ and $z$ of a cluster algebra $A(x, B)$ are disjoint if $\{y_1, \ldots, y_n\} \cap \{z_1, \ldots, z_n\} = \emptyset$.

The next result gives a useful criterion when a cluster algebra is a factorial ring.

Theorem 1.4. Let $y$ and $z$ be disjoint clusters of $A(x, B)$. If there is a subalgebra $U$ of $A(x, B)$, such that $U$ is factorial and

$\{y_1, \ldots, y_n, z_1, \ldots, z_n, x_{n+1}^{\pm 1}, \ldots, x_p^{\pm 1}, x_{p+1}, \ldots, x_m\} \subset U$,

then

$U = A(x, B) = U(y, z)$.

In particular, $A(x, B)$ is factorial and all cluster variables are prime.

We obtain the following corollary on upper bounds of factorial cluster algebras.
Corollary 1.5. Assume that $\mathcal{A}(x, B)$ is factorial.

(i) If $y$ and $z$ are disjoint clusters of $\mathcal{A}(x, B)$, then $\mathcal{A}(x, B) = U(y, z)$.

(ii) For any $(y, C) \sim (x, B)$ we have $\mathcal{A}(x, B) = U(y, C)$.

In Section 7 we apply the above results to show that many cluster algebras are polynomial rings. In Section 8 we discuss some further applications concerning the dual of Lusztig’s semicanonical basis and monoidal categorifications of cluster algebras.

1.9. Factoriality and maximal rank. In Section 6.1 we give examples of cluster algebras $\mathcal{A}(x, B)$, which are not factorial. In these examples, $B$ does not have maximal rank.

After we presented our results at the Abel Symposium in Balestrand in June 2011, Zelevinsky asked the following question:

Problem 1.6. Suppose $(x, B)$ is a seed of $\mathcal{F}$ such that $B$ has maximal rank. Does it follow that $\mathcal{A}(x, B)$ is factorial?

After we circulated a first version of this article, Philipp Lampe [La] discovered an example of a non-factorial cluster algebra $\mathcal{A}(x, B)$ with $B$ having maximal rank. With his permission, we explain a generalization of his example in Section 6.2.

2. Invertible elements in cluster algebras

In this section we prove Theorem 1.3(i), classifying the invertible elements of cluster algebras.

The following lemma is straightforward and well-known.

Lemma 2.1. For any seed $(x, B)$ of $\mathcal{F}$ we have

$$L_x^\times = \{\lambda x_1^{a_1} \cdots x_p^{a_p} | \lambda \in K^\times, a_i \in \mathbb{Z}\}.$$  

Theorem 2.2. For any seed $(x, B)$ of $\mathcal{F}$ we have

$$\mathcal{A}(x, B)^\times = \{\lambda x_{n+1}^{a_{n+1}} \cdots x_p^{a_p} | \lambda \in K^\times, a_i \in \mathbb{Z}\}.$$  

Proof. Let $u$ be an invertible element in $\mathcal{A}(x, B)$, and let $(y, C)$ be any seed of $\mathcal{A}(x, B)$. By the Laurent phenomenon Theorem 1.1 we know that $\mathcal{A}(x, B) \subseteq L_y$. It follows that $u$ is also invertible in $L_y$. Thus by Lemma 2.1 there are $a_1, \ldots, a_p \in \mathbb{Z}$ and $\lambda \in K^\times$ such that $u = \lambda M$, where

$$M = y_1^{a_1} \cdots y_k^{a_k} \cdots y_p^{a_p}.$$  

If all $a_i$ with $1 \leq i \leq n$ are zero, we are done. To get a contradiction, assume that there is some $1 \leq k \leq n$ with $a_k \neq 0$. 

Documenta Mathematica 18 (2013) 249–274
Let $y_k^*: =\mu_{(y,C)}(y_k)$. Again the Laurent phenomenon yields $b_1, \ldots, b_p \in \mathbb{Z}$ and $\nu \in K^\times$ such that

$$u = \nu y_1^{b_1} \cdots y_{k-1}^{b_{k-1}} (y_k^{*})^{b_k} y_{k+1}^{b_{k+1}} \cdots y_p^{b_p}.$$ 

Without loss of generality let $b_k \geq 0$. (Otherwise we can work with $u^{-1}$ instead of $u$.) If $b_k = 0$, we get

$$\lambda y_1^{a_1} \cdots y_k^{a_k} \cdots y_p^{a_p} = \nu y_1^{b_1} \cdots y_{k-1}^{b_{k-1}} y_{k+1}^{b_{k+1}} \cdots y_p^{b_p},$$

where $\lambda, \nu \in K^\times$. This is a contradiction, because $a_k \neq 0$ and $y_1, \ldots, y_m$ are algebraically independent, and therefore Laurent monomials in $y_1, \ldots, y_m$ are linearly independent in $\mathcal{F}$.

Next, assume that $b_k > 0$. By definition we have

$$y_k^* = M_1 + M_2$$

with

$$M_1 = y_k^{-1} \prod_{c_{ik} > 0} y_i^{c_{ik}} \quad \text{and} \quad M_2 = y_k^{-1} \prod_{c_{ik} < 0} y_i^{-c_{ik}},$$

where the products run over the positive, respectively negative, entries in the $k$th column of the matrix $C$.

Thus we get an equality of the form

$$(2) \quad u = \lambda M = \nu (y_1^{b_1} \cdots y_{k-1}^{b_{k-1}}) (M_1 + M_2) y_k^{b_k} (y_{k+1}^{b_{k+1}} \cdots y_p^{b_p}).$$

We know that $M_1 \neq M_2$. (Here we use that $m > 1$ and that exchange matrices are by definition connected. Otherwise, one could get exchange relations of the form $x_k x_k^i = 1 + 1$.) Thus the right-hand side of Equation $(2)$ is a non-trivial linear combination of $b_k + 1 \geq 2$ pairwise different Laurent monomials in $y_1, \ldots, y_m$. This is again a contradiction, since $y_1, \ldots, y_m$ are algebraically independent. \hfill \Box

**Corollary 2.3.** For any seed $(x, B)$ of $\mathcal{F}$ the following hold:

(i) Let $y$ and $z$ be non-zero elements in $\mathcal{A}(x, B)$. Then $y$ and $z$ are associate if and only if there exist $a_{n+1}, \ldots, a_p \in \mathbb{Z}$ and $\lambda \in K^\times$ with

$$y = \lambda x_1^{a_{n+1}} \cdots x_p^{a_p} z.$$ 

(ii) Let $y$ and $z$ be cluster variables of $\mathcal{A}(x, B)$. Then $y$ and $z$ are associate if and only if $y = z$.

**Proof.** Part (i) follows directly from Theorem 2.2. To prove (ii), let $y$ and $z$ be clusters of $\mathcal{A}(x, B)$. Assume $y_i$ and $z_j$ are associate for some $1 \leq i, j \leq n$. By (i) there are $a_{n+1}, \ldots, a_p \in \mathbb{Z}$ and $\lambda \in K^\times$ with $y_i = \lambda x_{n+1}^{a_{n+1}} \cdots x_p^{a_p} z_j$. By
Theorem 1.1 we know that there exist $b_1, \ldots, b_n \in \mathbb{Z}$ and a polynomial $f$ in $\mathbb{Z}[z_1, \ldots, z_m]$ with

$$y_i = \frac{f}{z_1^{b_1} \cdots z_n^{b_n}}$$

and $f$ is not divisible by any $z_1, \ldots, z_n$. The polynomial $f$ and $b_1, \ldots, b_n$ are uniquely determined by $y_i$. It follows that $\lambda \in \mathbb{Z}$ and $a_{n+1}, \ldots, a_p \geq 0$. But we also have $z_j = \lambda^{-1}x_{n+1}^{-a_{n+1}} \cdots x_p^{-a_p}y_i$. Reversing the role of $y_i$ and $z_j$ we get $-a_{n+1}, \ldots, -a_p \geq 0$ and $\lambda = \frac{y_i}{z_j}$. This implies $y_i = z_j$ or $-y_i = z_j$. By the remark at the beginning of Section 1.3 we know that $z_j = \frac{f}{g}$ for some $f, g \in \mathbb{N}[y_1, \ldots, y_m]$. Assume that $-y_i = z_j$. We get $z_j = -y_i = f/g$ and therefore $f + y_ig = 0$. This is a contradiction to the algebraic independence of $y_1, \ldots, y_m$. Thus we proved (ii).

We thank Giovanni Cerulli Irelli for helping us with the final step of the proof of Corollary 2.3(ii).

Two clusters $y$ and $z$ of a cluster algebra $A(x, B)$ are non-associate if there are no $1 \leq i, j \leq n$ such that $y_i$ and $z_j$ are associate.

**Corollary 2.4.** For clusters $y$ and $z$ of $A(x, B)$ the following are equivalent:

(i) The clusters $y$ and $z$ are non-associate.

(ii) The clusters $y$ and $z$ are disjoint.

**Proof.** Non-associate clusters are obviously disjoint. The converse follows directly from Corollary 2.3(ii).

3. Irreducibility of cluster variables

In this section we prove Theorem 1.3(ii). The proof is very similar to the proof of Theorem 2.2.

**Theorem 3.1.** Let $(x, B)$ be a seed of $F$. Then any cluster variable in $A(x, B)$ is irreducible.

**Proof.** Let $(y, C)$ be any seed of $A(x, B)$. We know from Theorem 2.2 that the cluster variables of $A(x, B)$ are non-invertible in $A(x, B)$.

Assume that $y_k$ is not irreducible for some $1 \leq k \leq n$. Thus $y_k = y_k' y_k''$ for some non-invertible elements $y_k'$ and $y_k''$ in $A(x, B)$. Since $y_k$ is invertible in $L_y$, we know that $y_k'$ and $y_k''$ are both invertible in $L_y$. Thus by Lemma 2.1 there are $a_s, b_i \in \mathbb{Z}$ and $\lambda, \lambda' \in K^\times$ with

$$y_k' = \lambda' y_1^{a_1} \cdots y_s^{a_s} \cdots y_p^{a_p}$$

and

$$y_k'' = \lambda'' y_1^{b_1} \cdots y_s^{b_s} \cdots y_p^{b_p}.$$ 

Since $y_k = y_k' y_k''$, we get $a_s + b_s = 0$ for all $s \neq k$ and $a_k + b_k = 1.$

Documenta Mathematica 18 (2013) 249–274
Assume that \( a_s = 0 \) for all \( 1 \leq s \leq n \) with \( s \neq k \). Then \( y'_k = \lambda' y_k^{a_k} y_{a_k+1}^{a+1} \cdots y_p^{a_p} \) and \( y''_k = \lambda'' y_k^{b_k} y_{b_k+1}^{b+1} \cdots y_p^{b_p} \). If \( a_k \leq 0 \), then \( y'_k \) is invertible in \( \mathcal{A}(x, B) \), and if \( a_k > 0 \), then \( y''_k \) is invertible in \( \mathcal{A}(x, B) \). In both cases we get a contradiction.

Next assume \( a_s \neq 0 \) for some \( 1 \leq s \leq n \) with \( s \neq k \). Let \( y^*_s := \mu_{(y, C)}(y_s) \). Thus we have

\[
y^*_s = M_1 + M_2
\]

with

\[
M_1 = y_s^{-1} \prod_{c_i > 0} y_i^{c_i} \quad \text{and} \quad M_2 = y_s^{-1} \prod_{c_i < 0} y_i^{-c_i},
\]

where the products run over the positive, respectively negative, entries in the \( s \)th column of the matrix \( C \).

Since \( s \neq k \), we see that \( y_k \) and therefore also \( y'_k \) and \( y''_k \) are invertible in \( \mathcal{L}_{\mu_{s}, (y, C)} \). Thus by Lemma 2.1 there are \( c_i, d_i \in \mathbb{Z} \) and \( \nu', \nu'' \in K^\times \) with

\[
y'_k = \nu' y_1^{c_1} \cdots y_{s-1}^{c_{s-1}} (y_s)^{c_s} y_{s+1}^{c_{s+1}} \cdots y_p^{c_p}
\]

and

\[
y''_k = \nu'' y_1^{d_1} \cdots y_{s-1}^{d_{s-1}} (y_s)^{d_s} y_{s+1}^{d_{s+1}} \cdots y_p^{d_p}.
\]

Note that \( c_s + d_s = 0 \). Without loss of generality we assume that \( c_s \geq 0 \). (If \( c_s < 0 \), we continue to work with \( y''_k \) instead of \( y'_k \).) If \( c_s = 0 \), we get

\[
y'_k = \lambda' y_1^{c_1} \cdots y_{s-1}^{c_{s-1}} y_s^{c_s} y_{s+1}^{c_{s+1}} \cdots y_p^{c_p} = \nu' y_1^{c_1} \cdots y_s^0 \cdots y_p^{c_p}.
\]

This is a contradiction, since \( a_s \neq 0 \) and \( y_1, \ldots, y_m \) are algebraically independent. If \( c_s > 0 \), then

\[
y'_k = \lambda' y_1^{c_1} \cdots y_{s-1}^{c_{s-1}} y_s^{c_s} y_{s+1}^{c_{s+1}} \cdots y_p^{c_p} = \nu' y_1^{c_1} \cdots y_{s-1}^{c_{s-1}} (y_s)^{c_s} y_{s+1}^{c_{s+1}} \cdots y_p^{c_p} = \nu' y_1^{c_1} \cdots y_{s-1}^{c_{s-1}} (M_1 + M_2)^{c_s} y_{s+1}^{c_{s+1}} \cdots y_p^{c_p}.
\]

We know that \( M_1 \neq M_2 \). Thus the Laurent monomial \( y_k \) is a non-trivial linear combination of \( c_s + 1 \geq 2 \) pairwise different Laurent monomials in \( y_1, \ldots, y_m \), a contradiction.

Note that the coefficients \( x_{p+1}, \ldots, x_m \) of \( \mathcal{A}(x, B) \) are obviously irreducible in \( \mathcal{L}_x \). Since \( \mathcal{A}(x, B) \subseteq \mathcal{L}_x \), they are also irreducible in \( \mathcal{A}(x, B) \).

4. Factorial cluster algebras

4.1. A factoriality criterion. This section contains the proofs of Theorem 4.4 and Corollary 4.5.

Theorem 4.1. Let \( y \) and \( z \) be disjoint clusters of \( \mathcal{A}(x, B) \), and let \( U \) be a factorial subalgebra of \( \mathcal{A}(x, B) \) such that

\[
\{y_1, \ldots, y_n, z_1, \ldots, z_m, x_{n+1}^{\pm1}, \ldots, x_p^{\pm1}, x_{p+1}, \ldots, x_m \} \subset U.
\]
Then we have

\[ U = \mathcal{A}(x, B) = U(y, z). \]

Proof. Let \( u \in U(y, z) = \mathcal{L}_y \cap \mathcal{L}_z \). Thus we have

\[ u = \frac{f}{y_1^{a_1} y_2^{a_2} \cdots y_p^{a_p}} = \frac{g}{z_1^{b_1} z_2^{b_2} \cdots z_p^{b_p}}, \]

where \( f \) is a polynomial in \( y_1, \ldots, y_m \), and \( g \) is a polynomial in \( z_1, \ldots, z_m \), and \( a_i, b_i \geq 0 \) for all \( 1 \leq i \leq p \). By the Laurent phenomenon it is enough to show that \( u \in U \).

Since \( y_i, z_i \in U \) for all \( 1 \leq i \leq m \), we get the identity

\[ f z_1^{b_1} z_2^{b_2} \cdots z_n^{b_n} \cdots z_{n+1}^{b_{n+1}} \cdots z_p^{b_p} = g y_1^{a_1} y_2^{a_2} \cdots y_n^{a_n} y_{n+1}^{a_{n+1}} \cdots y_p^{a_p} \]

in \( U \).

By Theorem 4.1 the cluster variables \( y_i \) and \( z_i \) with \( 1 \leq i \leq n \) are irreducible in \( \mathcal{A}(x, B) \). In particular, they are irreducible in the subalgebra \( U \) of \( \mathcal{A}(x, B) \). The elements \( y_n^{a_n+1} \cdots y_p^{a_p} \) and \( z_{n+1}^{b_{n+1}} \cdots z_p^{b_p} \) are units in \( U \). (Recall that \( x_i = y_i = z_i \) for all \( n+1 \leq i \leq m \).)

The clusters \( y \) and \( z \) are disjoint. Now Corollary 2.4 implies that the elements \( y_i \) and \( z_j \) are non-associate for all \( 1 \leq i, j \leq n \). Thus, by the factoriality of \( U \), the monomial \( y_1^{a_1} y_2^{a_2} \cdots y_n^{a_n} \) divides \( f \) in \( U \). In other words there is some \( h \in U \) with \( f = h y_1^{a_1} y_2^{a_2} \cdots y_n^{a_n} \). It follows that

\[ u = \frac{f}{y_1^{a_1} y_2^{a_2} \cdots y_p^{a_p}} = \frac{h y_1^{a_1} y_2^{a_2} \cdots y_n^{a_n}}{y_1^{a_1} y_2^{a_2} \cdots y_p^{a_p}} = \frac{h}{y_n^{a_n+1} \cdots y_p^{a_p}} = hy_n^{a_n+1} \cdots y_p^{a_p}. \]

Since \( h \in U \) and \( y_n^{a_n+1} \cdots y_p^{a_p} \in U \), we get \( u \in U \). This finishes the proof. \( \square \)

Corollary 4.2. Assume that \( \mathcal{A}(x, B) \) is factorial.

(i) If \( y \) and \( z \) are disjoint clusters of \( \mathcal{A}(x, B) \), then \( \mathcal{A}(x, B) = U(y, z) \).

(ii) For any \( (y, C) \sim (x, B) \) we have \( \mathcal{A}(x, B) = U(y, C) \).

Proof. Part (i) follows directly from Theorem 4.1. To prove part (ii), assume \( (y, C) \sim (x, B) \) and let \( u \in U(y, C) \). For \( 1 \leq k \leq n \) let \( (y_k, C_k) := \mu_k(y, C) \) and \( y_k^* := \mu_{(y, C)}(y_k) \). We get

\[ u = \frac{f}{y_1^{a_1} \cdots y_k^{a_k} \cdots y_p^{a_p}} = \frac{f_k}{y_1^{b_1} \cdots (y_k^*)^{b_k} \cdots y_p^{b_p}} \]

for a polynomial \( f \) in \( y_1, \ldots, y_k, \ldots, y_m \), a polynomial \( f_k \) in \( y_1, \ldots, y_k^*, \ldots, y_m \), and \( a_i, b_i \geq 0 \). This yields an equality

\[ f y_1^{b_1} \cdots (y_k^*)^{b_k} \cdots y_p^{b_p} = f_k y_1^{a_1} \cdots y_k^{a_k} \cdots y_p^{a_p} \]

in \( \mathcal{A}(x, B) \). Now we argue similarly as in the proof of Theorem 4.1. The cluster variables \( y_1, \ldots, y_n, y_1^*, \ldots, y_n^* \) are obviously pairwise different. Now
For \( k \leq 1 \) and \( y \) that follows that \( y \in A \) the existence of disjoint clusters in \( y \). Since \( u \in A(x, B) \), Equation 1 implies that \( y^{y_0} \) divides \( f \) in \( A(x, B) \). Since this holds for all \( 1 \leq k \leq n \), we get that \( y_{y_0}^1 \cdots y_{y_0}^{n_0} \) divides \( f \) in \( A(x, B) \). It follows that \( u \in A(x, B) \).

4.2. EXISTENCE OF DISJOINT CLUSTERS. One assumption of Theorem 4.1 is the existence of disjoint clusters in \( A(x, B) \). We can prove this under a mild assumption. But it should be true in general.

**Proposition 4.3.** Assume that the cluster monomials of \( A(x, B) \) are linearly independent. Let \( (y, C) \) be a seed of \( A(x, B) \), and let 

\[
(z, D) := \mu_n \cdots \mu_2 \mu_1 (y, C).
\]

Then the clusters \( y \) and \( z \) are disjoint.

**Proof.** Set \( (y[0], C[0]) := (y, C) \), and for \( 1 \leq k \leq n \) let \( (y[k], C[k]) := \mu_k (y[k-1], C[k-1]) \) and \( (y_1[k], \ldots, y_m[k]) := y[k] \). We claim that 

\[
\{y_1[k], \ldots, y_k[k]\} \cap \{y_1, \ldots, y_n\} = \emptyset.
\]

For \( k = 1 \) this is straightforward. Thus let \( k \geq 2 \) and assume that our claim is true for \( k - 1 \). To get a contradiction, assume that \( y_k[k] = y_j \) for some \( 1 \leq j \leq n \). By the induction assumption we know that \( \{y_1[k], \ldots, y_{k-1}[k]\} \cap \{y_1, \ldots, y_n\} = \emptyset \), since \( y_i[k] = y_i[k-1] \) for all \( 1 \leq i \leq k - 1 \).

We have \( y[k] = (y_1[k], \ldots, y_k[k], y_{k+1}, \ldots, y_m) \).

Since \( y_1[k], \ldots, y_k[k], y_{k+1}, \ldots, y_m \) are algebraically independent and \( y_k[k] \neq y_k \), we get \( 1 \leq j \leq k - 1 \). Since \( (y[j], C[j]) = \mu_j (y[j-1], C[j-1]) \), it follows that \( (y[j-1], y_j[j]) \) is an exchange pair of \( A(x, B) \). Next, observe that \( y_k[k] = y_j = y_j[j-1] \) and \( y_j[k] = y_j[j] \). Thus \( y_j[j-1] \) and \( y_j[j] \) are both contained in \( \{y_1[k], \ldots, y_m[k]\} \), and therefore \( y_j[j-1]y_j[j] \) is a cluster monomial. The corresponding exchange relation gives a contradiction to the linear independence of cluster monomials.

Fomin and Zelevinsky [FZ3, Conjecture 4.16] conjecture that the cluster monomials of \( A(x, B) \) are always linearly independent. Under the assumptions that \( B \) has maximal rank and that \( B^2 \) is skew-symmetric, the conjecture follows from [DWZ, Theorem 1.7].

5. THE DIVISIBILITY GROUP OF A CLUSTER ALGEBRA

Let \( R \) be an integral domain, and let \( \text{Frac}(R) \) be the field of fractions of \( R \). Set \( \text{Frac}(R)^* := \text{Frac}(R) \setminus \{0\} \). The abelian group 

\[
G(R) := (\text{Frac}(R)^*/R^x, \cdot)
\]

is the divisibility group of \( R \).
For $g, h \in \text{Frac}(R)^*$ let $g \leq h$ provided $hg^{-1} \in R$. This relation is reflexive and transitive and it induces a partial ordering on $G(R)$.

Let $I$ be a set. The abelian group $(\mathbb{Z}(I), +)$ is equipped with the following partial ordering: We set $(x_i)_{i \in I} \leq (y_i)_{i \in I}$ if $x_i \leq y_i$ for all $i$. (By definition, the elements in $\mathbb{Z}(I)$ are tuples $(x_i)_{i \in I}$ of integers $x_i$ such that only finitely many $x_i$ are non-zero.)

There is the following well-known criterion for the factoriality of $R$, see for example [C, Section 2].

**Proposition 5.1.** For an integral domain $R$ the following are equivalent:

(i) $R$ is factorial.

(ii) There is a set $I$ and a group isomorphism

$$\phi: G(R) \to \mathbb{Z}(I)$$

such that for all $g, h \in G(R)$ we have $g \leq h$ if and only if $\phi(g) \leq \phi(h)$.

Not all cluster algebras $A(\mathbf{x}, B)$ are factorial, but at least one part of the above factoriality criterion is satisfied:

**Proposition 5.2.** For any seed $(\mathbf{x}, B)$ of $\mathcal{F}$ the divisibility group $G(A(\mathbf{x}, B))$ is isomorphic to $\mathbb{Z}(I)$, where

$I := \{ f \in K[x_1, \ldots, x_m] \mid f \text{ is irreducible and } f \not\equiv x_i \text{ for } n+1 \leq i \leq p \}/K^*$

is the set of irreducible polynomials unequal to any $x_{n+1}, \ldots, x_p$ in $K[x_1, \ldots, x_m]$ up to non-zero scalar multiples.

**Proof.** By the Laurent phenomenon and the definition of a seed we get

$$\text{Frac}(A(\mathbf{x}, B)) = \text{Frac}(\mathcal{Z}_\mathbf{x}) = K(x_1, \ldots, x_m).$$

Furthermore, by Theorem 2.2 we have

$$A(\mathbf{x}, B)^\times = \{ \lambda x_{n+1}^{a_{n+1}} \cdots x_p^{a_p} \mid \lambda \in K^*, a_i \in \mathbb{Z} \}.$$  

Any element in $K(x_1, \ldots, x_m)$ is of the form $f_1 \cdots f_m g_1^{-1} \cdots g_i^{-1}$ with $f_j, g_j$ irreducible in $K[x_1, \ldots, x_m]$. Using that the polynomial ring $K[x_1, \ldots, x_m]$ is factorial, and working modulo $A(\mathbf{x}, B)^\times$ yields the result. \qed

6. Examples of non-factorial cluster algebras

6.1. For a matrix $A \in M_{m,n}(\mathbb{Z})$ and $1 \leq i \leq n$ let $c_i(A)$ be the $i$th column of $A$.

**Proposition 6.1.** Let $(\mathbf{x}, B)$ be a seed of $\mathcal{F}$. Assume that $c_k(B) = c_s(B)$ or $c_k(B) = -c_s(B)$ for some $k \neq s$ with $b_{ks} = 0$. Then $A(\mathbf{x}, B)$ is not factorial.
Proof. Define \((y, C) := \mu_k(x, B)\) and \((z, D) := \mu_s(y, C)\). We get
\[ y_k = z_k = x_k^{-1}(M_1 + M_2), \]
where
\[ M_1 := \prod_{b_{ik} > 0} x_i^{b_{ik}} \quad \text{and} \quad M_2 := \prod_{b_{ik} < 0} x_i^{-b_{ik}}. \]
By the mutation rule, we have \(c_k(C) = -c_k(B)\), and since \(b_{ks} = 0\), we get \(c_s(C) = c_s(B)\). Since \(c_s(B) = c_k(B)\) or \(c_s(B) = -c_k(B)\), this implies that
\[ z_s = x_s^{-1}(M_1 + M_2). \]
The cluster variables \(x_k, x_s, z_k, z_s\) are pairwise different. Thus they are pairwise non-associate by Corollary 2.3(ii), and by Theorem 3.1 they are irreducible in \(A(x, B)\). Obviously, we have
\[ x_kz_k = x_sz_s. \]
Thus \(A(x, B)\) is not factorial. 

To give a concrete example of a cluster algebra, which is not factorial, assume \(m = n = p = 3\), and let \(B \in M_{m,n}(\mathbb{Z})\) be the matrix
\[
B = \begin{pmatrix}
0 & -1 & 0 \\
1 & 0 & -1 \\
0 & 1 & 0 
\end{pmatrix}.
\]
The matrix \(B\) obviously satisfies the assumptions of Proposition 6.1. Note that \(B = B^\circ\) is skew-symmetric, and that \(\Gamma(B)\) is the quiver
\[
3 \rightarrow 2 \rightarrow 1.
\]
Thus \(A(x, B)\) is a cluster algebra of Dynkin type \(A_3\). (Cluster algebras with finitely many cluster variables are classified via Dynkin types, for details see [FZ2].)

Define \((z, D) := \mu_3 \mu_1(x, B)\). We get \(z_1 = x_1^{-1}(1 + x_2)\), \(z_3 = x_3^{-1}(1 + x_2)\) and therefore \(x_1z_1 = x_3z_3\).

Clearly, the cluster variables \(x_1, x_3, z_1, z_3\) are pairwise different. Using Corollary 2.3(ii) we get that \(x_1, x_3, z_1, z_3\) are pairwise non-associate, and by Theorem 3.1 they are irreducible. Thus \(A(x, B)\) is not factorial.

6.2. The next example is due to Philipp Lampe. It gives a negative answer to Zelevinsky’s Question 1.6.

Proposition 6.2 (La). Let \(K = \mathbb{C}\), \(m = n = 2\) and
\[
B = \begin{pmatrix}
0 & -2 \\
2 & 0 
\end{pmatrix}.
\]
Then \(A(x, B)\) is not factorial.
The proof of the following result is a straightforward generalization of Lampe’s proof of Proposition 6.3.

**Proposition 6.3.** Let $(x, B)$ be a seed of $\mathcal{F}$. Assume that there exists some $1 \leq k \leq n$ such that the polynomial $X^d + Y^d$ is not irreducible in $K[X,Y]$, where $d := \gcd(b_{1k}, \ldots, b_{nk})$ is the greatest common divisor of $b_{1k}, \ldots, b_{nk}$. Then $\mathcal{A}(x, B)$ is not factorial.

**Proof.** Let $X^d + Y^d = f_1 \cdots f_t$, where the $f_j$ are irreducible polynomials in $K[X,Y]$. Since $X^d + Y^d$ is not irreducible in $K[X,Y]$, we have $t \geq 2$. Let $y_k := \mu_{(x,B)}(x_k)$. The corresponding exchange relation is

$$x_k y_k = \prod_{b_{ik} > 0} x_i^{b_{ik}} + \prod_{b_{ik} < 0} x_i^{-b_{ik}} = M^d + N^d = \prod_{j=1}^t f_j(M,N),$$

where

$$M := \prod_{b_{ik} > 0} x_i^{b_{ik}/d} \quad \text{and} \quad N := \prod_{b_{ik} < 0} x_i^{-b_{ik}/d}.$$

Clearly, each $f_j(M,N)$ is contained in $\mathcal{A}(x, B)$. To get a contradiction, assume that $\mathcal{A}(x, B)$ is factorial. By Theorem 2.2 none of the elements $f_j(M,N)$ is invertible in $\mathcal{A}(x, B)$. Since $\mathcal{A}(x, B)$ is factorial, each $f_j(M,N)$ is equal to a product $f_{1j} \cdots f_{aj,j}$, where the $f_{ij}$ are irreducible in $\mathcal{A}(x, B)$ and $a_j \geq 1$. By Theorem 3.1 the cluster variables $x_k$ and $y_k$ are irreducible in $\mathcal{A}(x, B)$. It follows that $a_1 + \cdots + a_t = 2$, since $\mathcal{A}(x, B)$ is factorial. This implies $t = 2$ and $a_1 = a_2 = 1$. In particular, $f_1(M,N)$ and $f_2(M,N)$ are irreducible in $\mathcal{A}(x, B)$, and we have $x_k y_k = f_1(M,N)f_2(M,N)$. For $j = 1, 2$ the elements $x_k$ and $f_j(M,N)$ cannot be associate, since $f_j(M,N)$ is just a $K$-linear combination of monomials in $\{x_1, \ldots, x_m\} \setminus \{x_k\}$. (Here we use Corollary 2.3(i) and the fact that $b_{kk} = 0$.) This is a contradiction to the factoriality of $\mathcal{A}(x, B)$. $\square$

Note that a polynomial of the form $X^d + Y^d$ is irreducible if and only if $X^d + 1$ is irreducible.

**Corollary 6.4.** Let $K = \mathbb{C}$, $m = n = 2$ and

$$B = \begin{pmatrix} 0 & -c \\ d & 0 \end{pmatrix}$$

with $c \geq 1$ and $d \geq 2$. Then $\mathcal{A}(x, B)$ is not factorial.

**Proof.** For $k = 1$ the assumptions of Proposition 6.3 hold. (We have $\gcd(0, d) = d$, and the polynomial $X^d + 1$ is not irreducible in $\mathbb{C}[X]$.) $\square$

**Corollary 6.5.** Let $m = n = 2$ and

$$B = \begin{pmatrix} 0 & -c \\ d & 0 \end{pmatrix}$$

with $c \geq 1$ and $d \geq 3$ an odd number. Then $\mathcal{A}(x, B)$ is not factorial.
Proof. For \( k = 1 \) the assumptions of Proposition 6.3 hold. (We have \( \gcd(0,d) = d \), and for odd \( d \) we have
\[
X^d + 1 = (X + 1) \left( \sum_{j=0}^{d-1} (-1)^j X^j \right).
\]
Thus \( X^d + 1 \) is not irreducible in \( K[X] \). \( \square \)

7. Examples of factorial cluster algebras

7.1. Cluster algebras of Dynkin type \( A \) as polynomial rings. Assume \( m = n + 1 = p + 1 \), and let \( B \in M_{m,n}(\mathbb{Z}) \) be the matrix
\[
B = \begin{pmatrix}
0 & -1 & 0 & -1 & \\
1 & 0 & -1 & \\
& 1 & 0 & -1 & \\
& & \\
& & & & \\
& & & & \\
& & & & \\
& & & & 1
\end{pmatrix}.
\]
Obviously, \( B^o \) is skew-symmetric, \( \Gamma(B) \) is the quiver
\[
\begin{aligned}
m &\longrightarrow \cdots \longrightarrow 2 \longrightarrow 1,
\end{aligned}
\]
and \( \mathcal{A}(x, B) \) is a cluster algebra of Dynkin type \( \mathbb{A}_n \). Note that \( \mathcal{A}(x, B) \) has exactly one coefficient, and that this coefficient is non-invertible.

Let \( (x[0], B[0]) := (x, B) \). For each \( 1 \leq i \leq m - 1 \) we define inductively a seed by
\[
(x[i], B[i]) := \mu_{m-i} \cdots \mu_2 \mu_1 (x[i-1], B[i-1]).
\]
For \( 0 \leq i \leq m - 1 \) set \( (x_1[i], \ldots, x_m[i]) := x[i] \).

For simplicity we define \( x_0[i] := 1 \) and \( x_{-1}[i] := 0 \) for all \( i \).

Lemma 7.1. For \( 0 \leq i \leq m - 2, 1 \leq k \leq m - 1 - i \) and \( 0 \leq j \leq i \) we have
\[
\mu_{(x[i], B[i])}(x_k[i]) = \frac{x_{k-1}[i] + x_{k+1}[i]}{x_k[i]} = \frac{x_{k-1+i}[i-j] + x_{k+1+i}[i-j]}{x_{k+j}[i-j]}.
\]

Proof. The first equality follows from the definition of \( (x[i], B[i]) \) and the mutation rule. The second equality is proved by induction on \( i \). \( \square \)

Corollary 7.2. For \( 0 \leq i \leq m - 2 \) we have
\[
\begin{aligned}
x_{i+2} &= x_1[i+1]x_{i+1} - x_i, \\
x_{i+1}[1] &= x_1[i+1]x_i[1] - x_{i-1}[1].
\end{aligned}
\]
Proof. Equation (5) follows from (4) for \( k = 1 \) and \( j = i \). The case \( k = 1 \) and \( j = i - 1 \) yields Equation (6).

\[\]

**Proposition 7.3.** The elements \( x_1[0], x_1[1], \ldots, x_1[m - 1] \) are algebraically independent and

\[ K[x_1[0], x_1[1], \ldots, x_1[m - 1]] = A(x, B). \]

In particular, the cluster algebra \( A(x, B) \) is a polynomial ring in \( m \) variables.

Proof. It follows from Equation (5) that

\[ x_1[i] \in K(x_1, \ldots, x_{i+1}) \setminus K(x_1, \ldots, x_i) \]

for all \( 1 \leq i \leq m - 1 \). Since \( x_1, \ldots, x_m \) are algebraically independent, this implies that \( x_1[0], x_1[1], \ldots, x_1[m - 1] \) are algebraically independent as well. Thus

\[ U := K[x_1[0], x_1[1], \ldots, x_1[m - 1]] \]

is a polynomial ring in \( m \) variables. In particular, \( U \) is factorial. Equation (5) implies that \( x_1, \ldots, x_m \in U \), and Equation (6) yields that \( x_1[1], \ldots, x_m[1] \in U \). Clearly, the clusters \( x \) and \( x[1] \) are disjoint. Thus the assumptions of Theorem 4.1 are satisfied, and we get \( U = A(x, B) \).

The cluster algebra \( A(x, B) \) as defined above has been studied by several people. It is related to a \( T \)-system of Dynkin type \( A_1 \) with a certain boundary condition, see [DK]. Furthermore, for \( K = \mathbb{C} \) the cluster algebra \( A(x, B) \) is naturally isomorphic to the complexified Grothendieck ring of the category \( C_n \) of finite-dimensional modules of level \( n \) over the quantum loop algebra of Dynkin type \( A_1 \), see [HL, N2]. It is well known, that \( A(x, B) \) is a polynomial ring. We just wanted to demonstrate how to use Theorem 4.1 in practise.

### 7.2. Acyclic cluster algebras as polynomial rings

Let \( C = (c_{ij}) \in M_{n,n}(\mathbb{Z}) \) be a generalized Cartan matrix, i.e. \( C \) is symmetrizable, \( c_{ii} = 2 \) for all \( i \) and \( c_{ij} \leq 0 \) for all \( i \neq j \).

Assume that \( m = 2n = 2p \), and let \( (x, B) \) be a seed of \( \mathcal{F} \), where \( B = (b_{ij}) \in M_{2n,n}(\mathbb{Z}) \) is defined as follows: For \( 1 \leq i \leq 2n \) and \( 1 \leq j \leq n \) let

\[
\begin{aligned}
  b_{ij} := &\begin{cases}
    0 & \text{if } i = j, \\
    -c_{ij} & \text{if } 1 \leq i < j \leq n, \\
    c_{ij} & \text{if } 1 \leq j < i \leq n, \\
    1 & \text{if } i = n + j, \\
    c_{i-n,j} & \text{if } n + 1 \leq i \leq 2n \text{ and } i - n < j, \\
    0 & \text{if } n + 1 \leq i \leq 2n \text{ and } i - n > j.
  \end{cases}
\end{aligned}
\]
Thus we have

\[
B = \begin{pmatrix}
0 & b_{12} & b_{13} & \cdots & b_{1n} \\
b_{21} & 0 & b_{23} & \cdots & b_{2n} \\
b_{31} & b_{32} & 0 & \ddots & : \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
b_{n1} & b_{n2} & \cdots & b_{n,n-1} & 0 \\
1 & -b_{12} & -b_{13} & \cdots & -b_{1n} \\
0 & 1 & -b_{23} & \cdots & -b_{2n} \\
0 & 0 & 1 & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

Clearly, \((x, B)\) is an acyclic seed. Namely, if \(i \rightarrow j\) is an arrow in \(\Sigma(B)\), then \(i < j\). Up to simultaneous reordering of columns and rows, each acyclic skew-symmetrizable matrix in \(M_{n,n}(\mathbb{Z})\) is of the form \(B^\circ\) with \(B\) defined as above. Note that \(A(x, B)\) has exactly \(n\) coefficients, and that all these coefficients are non-invertible.

For \(1 \leq i \leq n\) let

\[
(x[1], B[1]) := \mu_n \cdots \mu_2 \mu_1 (x, B)
\]

and \((x_1[1], \ldots, x_{2n}[1]) := x[1]\). Let \(B_0 := B\), and for \(1 \leq i \leq n\) let \(B_i := \mu_i(B_{i-1})\). Thus we have \(B_n = B[1]\). It is easy to work out the matrices \(B_i\) explicitly: The matrix \(B_i\) is obtained from \(B_{i-1}\) by changing the sign in the \(i\)th row and the \(i\)th column of the principal part \(B^\circ_{i-1}\). Furthermore, the \((n+i)\)th row of \(B_{i-1}\) gets replaced by

\[
(0, \ldots, 0, 1, -b_{i,i+1}, -b_{i,i+2}, \ldots, -b_{in})
\]

of \(B_{i-1}\) gets replaced by

\[
(-b_{1i}, -b_{2i}, \ldots, -b_{i,i-1}, -1, 0, \ldots, 0).
\]

If we write \(N_+\) (resp. \(N_-\)) for the upper (resp. lower) triangular part of \(B^\circ\), we get

\[
B = \begin{pmatrix}
1 & N_+ \\
\cdots & \cdots \\
N_- & 1 & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
0 & \cdots & \cdots & \cdots & 1
\end{pmatrix} \quad \text{and} \quad B[1] = \begin{pmatrix}
1 & N_+ \\
\cdots & \cdots \\
N_- & 1 & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
-N_- & -1 & \cdots & \cdots & \cdots
\end{pmatrix}.
\]

In particular, the principal part \(B^\circ\) of \(B\) is equal to the principal part \(B[1]^\circ\) of \(B[1]\).
Now the definition of seed mutation yields

\[(7)\quad x_k[1] = x_k^{-1}\left(x_{n+k} + \prod_{i=1}^{k-1} x_i[1]^{b_{ik}} \prod_{i=k+1}^{n} x_i^{-b_{ik}}\right)\]

for \(1 \leq k \leq n\).

**Proposition 7.4.** The elements \(x_1, \ldots, x_n, x_1[1], \ldots, x_n[1]\) are algebraically independent and

\[K[x_1, \ldots, x_n, x_1[1], \ldots, x_n[1]] = A(x, B).\]

In particular, the cluster algebra \(A(x, B)\) is a polynomial ring in \(2n\) variables.

**Proof.** By Equation (7) and induction we have

\[x_k[1] \in K[x_1, \ldots, x_{n+k}] \setminus K[x_1, \ldots, x_{n+k-1}]\]

for all \(1 \leq k \leq n\). It follows that \(x_1, \ldots, x_n, x_1[1], \ldots, x_n[1]\) are algebraically independent, and that the clusters \(x\) and \(x[1]\) are disjoint. Let \(U := K[x_1, \ldots, x_n, x_1[1], \ldots, x_n[1]]\).

Thus \(U\) is a polynomial ring in \(2n\) variables. In particular, \(U\) is factorial. It follows from Equation (7) that

\[(8)\quad x_{n+k} = x_k[1]x_k - \prod_{i=1}^{k-1} x_i[1]^{b_{ik}} \prod_{i=k+1}^{n} x_i^{-b_{ik}}.\]

This implies \(x_{n+k} \in U\) for all \(1 \leq k \leq n\). Thus the assumptions of Theorem 4.1 are satisfied, and we can conclude that \(U = A(x, B)\). \(\square\)

**Proposition 7.4** is a special case of a much more general result proved in [GLS2]. But the proof presented here is new and more elementary.

Next, we compare the basis

\[P_{GLS} := \{x[a] := x_1^{a_1} \cdots x_n^{a_n} x_1[1]^{a_{n+1}} \cdots x_n[1]^{a_{2n}} \mid a = (a_1, \ldots, a_{2n}) \in \mathbb{N}^{2n}\}\]

of \(A(x, B)\) resulting from Proposition 7.4 with a basis constructed by Berenstein, Fomin and Zelevinsky [BFZ]. For \(1 \leq k \leq n\) let

\[(9)\quad x'_k := \mu(x, B)(x_k) = x_k^{-1}\left(x_{n+k} \prod_{i=1}^{k-1} x_i^{b_{ik}} + \prod_{i=k+1}^{n} x_i^{-b_{ik}} \prod_{i=1}^{k-1} x_{n+i}^{-b_{ik}}\right)\]

and set

\[P_{BFZ} := \{x'[a] := x_1^{a_1} \cdots x_n^{a_n} x_1[1]^{a_{n+1}} \cdots x_n[1]^{a_{2n}} (x'_1)^{a_{2n+1}} \cdots (x'_n)^{a_{2n}} \mid a = (a_1, \ldots, a_{3n}) \in \mathbb{N}^{3n}, a_k a_{2n+k} = 0 \text{ for } 1 \leq k \leq n\}.\]

**Proposition 7.5** ([BFZ Corollary 1.21]). The set \(P_{BFZ}\) is a basis of \(A(x, B)\).
Note that the basis $P_{\text{GLS}}$ is constructed by using cluster variables from two seeds, namely $(x, B)$ and $\mu_n \cdots \mu_1(x, B)$, whereas $P_{\text{BFZ}}$ uses cluster variables from $n + 1$ seeds, namely $(x, B)$ and $\mu_k(x, B)$, where $1 \leq k \leq n$.

Now we insert Equation (8) into Equation (9) and obtain

\begin{equation}
(10) \quad x_k x'_k = \left( x_k[1] - \prod_{i=1}^{k-1} x_i[1]^{b_{ik}} \prod_{i=k+1}^{n} x_i^{b_{ik}} \right) \prod_{i=1}^{k-1} x_i^{b_{ik}} + \\
\prod_{i=k+1}^{n} x_i^{b_{ik}} \prod_{i=1}^{k-1} \left( x_i[1] - \prod_{j=1}^{i-1} x_j[1]^{b_{ij}} \prod_{j=i+1}^{n} x_j^{-b_{ij}} \right) b_{ik}.
\end{equation}

Then we observe that the right-hand side of Equation (10) is divisible by $x_k$ and that $x'_k$ is a polynomial in $x_1, \ldots, x_n, x_1[1], \ldots, x_n[1]$. Thus we can express every element of the basis $P_{\text{BFZ}}$ explicitly as a linear combination of vectors from the basis $P_{\text{GLS}}$.

One could use Equation (10) to get an alternative proof of Proposition 7.4 as pointed out by Zelevinsky [Z]. Vice versa, using Proposition 7.4 yields another proof that $P_{\text{BFZ}}$ is a basis.

As an illustration, for $n = 3$ the matrices $B_i$ look as follows:

\begin{align*}
B_0 &= \begin{pmatrix}
0 & b_{12} & b_{13} \\
b_{21} & 0 & b_{23} \\
b_{31} & b_{32} & 0 \\
1 & -b_{12} & -b_{13} \\
0 & 1 & -b_{23} \\
0 & 0 & 1
\end{pmatrix}, & B_1 &= \begin{pmatrix}
0 & -b_{12} & -b_{13} \\
b_{21} & 0 & b_{23} \\
b_{31} & b_{32} & 0 \\
-1 & 0 & 0 \\
0 & 1 & -b_{23} \\
0 & 0 & 1
\end{pmatrix}, \\
B_2 &= \begin{pmatrix}
0 & b_{12} & -b_{13} \\
b_{21} & 0 & -b_{23} \\
-b_{31} & -b_{32} & 0 \\
-1 & 0 & 0 \\
-b_{21} & -1 & 0 \\
0 & 0 & 1
\end{pmatrix}, & B_3 &= \begin{pmatrix}
0 & b_{12} & b_{13} \\
b_{21} & 0 & b_{23} \\
b_{31} & b_{32} & 0 \\
-1 & 0 & 0 \\
-b_{21} & -1 & 0 \\
-b_{31} & -b_{32} & -1
\end{pmatrix}.
\end{align*}

For example, for

\begin{equation}
B = B_0 = \begin{pmatrix}
0 & 2 & 0 \\
-2 & 0 & 1 \\
0 & -1 & 0 \\
1 & -2 & 0 \\
0 & 1 & -1 \\
0 & 0 & 1
\end{pmatrix}
\end{equation}
the quivers $\Gamma(B_0)$ and $\Gamma(B_3)$ look as follows:

$\Gamma(B_0)$: 

```
\[ \begin{array}{c}
5 & 4 & 1 & 2 & 3 & 6 \\
\searrow & \nearrow & \downarrow & \nearrow & \searrow & \downarrow \\
\end{array} \]
```

$\Gamma(B_3)$: 

```
\[ \begin{array}{c}
5 & 4 & 1 & 2 & 3 & 6 \\
\searrow & \nearrow & \downarrow & \nearrow & \searrow & \downarrow \\
\end{array} \]
```

The cluster algebra $A(x, B)$ is a polynomial ring in the 6 variables $x_1, x_2, x_3$ and

- $x_1[1] = \frac{x_2^2 + x_4}{x_1}$,
- $x_2[1] = \frac{x_1^2 x_3 + 2 x_2^3 x_4 + x_3 x_2^2 + x_1^3 x_2}{x_1^2 x_2}$,
- $x_3[1] = \frac{x_2^3 x_3 + 2 x_2^3 x_4 + x_3 x_2^2 + x_1^3 x_3 + x_1^2 x_2 x_6}{x_1^2 x_2 x_3}$.

7.3. Cluster algebras arising in Lie theory as polynomial rings.

The next class of examples can be seen as a fusion of the examples discussed in Sections 7.1 and 7.2. In the following we use the same notation as in [GLS 2].

Let $C \in M_{n,n}(\mathbb{Z})$ be a symmetric generalized Cartan matrix, and let $g$ be the associated Kac-Moody Lie algebra over $K = \mathbb{C}$ with triangular decomposition $g = n^- \oplus h \oplus n$, see [K].

Let $U(n)^*_gr$ be the graded dual of the enveloping algebra $U(n)$ of $n$. To each element $w$ in the Weyl group $W$ of $g$ one can associate a subalgebra $R(C_w)$ of $U(n)^*_gr$ and a cluster algebra $A(C_w)$, see [GLS 2]. Here $C_w$ denotes a Frobenius category associated to $w$, see [BIRS, GLS 2].

In [GLS 2] we constructed a natural algebra isomorphism

$$A(C_w) \rightarrow R(C_w).$$

This yields a cluster algebra structure on $R(C_w)$.

Let $i = (i_1, \ldots, i_r)$ be a reduced expression of $w$. In [GLS 2] we studied two cluster-tilting modules $V_i = V_{i_1} \oplus \cdots \oplus V_{i_r}$ and $T_i = T_{i_1} \oplus \cdots \oplus T_{i_r}$ in $C_w$, which are associated to $i$. These modules yield two disjoint clusters $(\delta_{V_1}, \ldots, \delta_{V_r})$ and $(\delta_{T_1}, \ldots, \delta_{T_r})$ of $R(C_w)$. The exchanges matrices are of size $r \times (r - n)$. In contrast to our conventions in this article, the $n$ coefficients are $\delta_{V_k} = \delta_{T_k}$ with $k^+ = r + 1$, where $k^+$ is defined as in [GLS 2], and none of these coefficients is invertible. Furthermore, we studied a module $M_i = M_{i_1} \oplus \cdots \oplus M_{i_r}$ in $C_w$, which yields cluster variables $\delta_{M_1}, \ldots, \delta_{M_r}$ of $R(C_w)$. (These do not form a cluster.) Using methods from Lie theory we obtained the following result.

**Theorem 7.6 ([GLS 2, Theorem 3.2]).** The cluster algebra $R(C_w)$ is a polynomial ring in the variables $\delta_{M_1}, \ldots, \delta_{M_r}$.
To obtain an alternative proof of Theorem 7.6, one can proceed as follows:

(i) Show that the cluster variables $\delta_{M_1}, \ldots, \delta_{M_r}$ are algebraically independent.

(ii) Show that for $1 \leq k \leq r$ the cluster variables $\delta_{V_k}$ and $\delta_{T_k}$ are polynomials in $\delta_{M_1}, \ldots, \delta_{M_r}$.

(iii) Apply Theorem 4.1.

Part (i) can be done easily using induction and the mutation sequence in [GLS2, Section 13]. Part (ii) is not at all straightforward.

Let us give a concrete example illustrating Theorem 7.6. Let $\mathfrak{g}$ be the Kac-Moody Lie algebra associated to the generalized Cartan matrix

$$C = \begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix},$$

and let $i = (2, 1, 2, 1, 2, 1, 2, 1)$. Then $\mathcal{A}(C_w) = \mathcal{A}(x, B_i)$, where $r = n + 2 = 8$, $x_7$ and $x_8$ are the (non-invertible) coefficients, and

$$B_i = \begin{pmatrix} 0 & 2 & -1 \\ -2 & 0 & 2 & -1 \\ 1 & -2 & 0 & 2 & -1 \\ 1 & -2 & 0 & 2 \\ 1 & -2 & 0 & \end{pmatrix}.$$

The principal part $B_i^\circ$ of $B_i$ is skew-symmetric, and the quiver $\Gamma(B_i)$ looks as follows:

![Quiver Diagram](image)

Define

$$(x[0], B[0]) := (x, B_i),$$

$$(x[1], B[1]) := \mu_5 \mu_3 \mu_1 (x[0], B[0]), \quad (x[2], B[2]) := \mu_6 \mu_4 \mu_2 (x[1], B[1]),$$

$$(x[3], B[3]) := \mu_3 \mu_1 (x[2], B[2]), \quad (x[4], B[4]) := \mu_4 \mu_2 (x[3], B[3]),$$

$$(x[5], B[5]) := \mu_1 (x[4], B[4]), \quad (x[6], B[6]) := \mu_2 (x[5], B[5]),$$

and for $0 \leq k \leq 6$ let $(x[k], \ldots, x[k]) := x[k]$.

Under the isomorphism $\mathcal{A}(C_w) \to \mathcal{R}(C_w)$ the cluster $x[0]$ of $\mathcal{A}(C_w) = \mathcal{A}(x, B_i)$ corresponds to the cluster $(\delta_{V_1}, \ldots, \delta_{V_8})$ of $\mathcal{R}(C_w)$, the cluster $x[6]$ corresponds...
to \((\delta_{T_1}, \ldots, \delta_{T_8})\), and we have
\[
\begin{align*}
x_1[0] &\mapsto \delta_{M_1}, \\
x_2[0] &\mapsto \delta_{M_2}, \\
x_1[2] &\mapsto \delta_{M_3}, \\
x_2[2] &\mapsto \delta_{M_4}, \\
x_1[4] &\mapsto \delta_{M_5}, \\
x_2[4] &\mapsto \delta_{M_6}, \\
x_1[6] &\mapsto \delta_{M_7}, \\
x_2[6] &\mapsto \delta_{M_8}.
\end{align*}
\]
By Theorem 7.6 we know that the cluster algebra \(A(x, B_1)\) is a polynomial ring in the variables \(x_1[0], x_2[0], x_1[2], x_2[2], x_1[4], x_2[4], x_1[6], x_2[6]\).

8. Applications

8.1. Prime elements in the dual semicanonical basis. As in Section 7.3 let \(C \in M_{n,n}(\mathbb{Z})\) be a symmetric generalized Cartan matrix, and let \(\mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}\) be the associated Lie algebra.

As before let \(W\) be the Weyl group of \(\mathfrak{g}\). To \(C\) one can also associate a preprojective algebra \(\Lambda\) over \(\mathbb{C}\), see for example [GLS2, R].

Lusztig [Lu] realized the universal enveloping algebra \(U(\mathfrak{n})\) of \(\mathfrak{n}\) as an algebra of constructible functions on the varieties \(\Lambda_d\) of nilpotent \(\Lambda\)-modules with dimension vector \(d \in \mathbb{N}^n\). He also constructed the semicanonical basis \(S\) of \(U(\mathfrak{n})\). The elements of \(S\) are naturally parametrized by the irreducible components of the varieties \(\Lambda_d\).

An irreducible component \(Z\) of \(\Lambda_d\) is called indecomposable if it contains a Zariski dense subset of indecomposable \(\Lambda\)-modules, and \(Z\) is rigid if it contains a rigid \(\Lambda\)-module \(M\), i.e. \(M\) is a module with \(\text{Ext}^1_{\Lambda}(M, M) = 0\).

Let \(S^*\) be the dual semicanonical basis of the graded dual \(U(\mathfrak{n})^*_{\text{gr}}\) of \(U(\mathfrak{n})\). The elements \(\rho_{Z}\) in \(S^*\) are also parametrized by irreducible components \(Z\) of the varieties \(\Lambda_d\). We call \(\rho_{Z}\) indecomposable (resp. rigid) if \(Z\) is indecomposable (resp. rigid). An element \(b \in S^*\) is called primitive if it cannot be written as a product \(b = b_1 b_2\) with \(b_1, b_2 \in S^* \setminus \{1\}\).

**Theorem 8.1** ([GLS1 Theorem 1.1]). If \(\rho_{Z}\) is primitive, then \(Z\) is indecomposable.

**Theorem 8.2** ([GLS2 Theorem 3.1]). For \(w \in W\) all cluster monomials of the cluster algebra \(\mathcal{R}(C_w)\) belong to the dual semicanonical basis \(S^*\) of \(U(\mathfrak{n})^*_{\text{gr}}\). More precisely, we have
\[
\{\text{cluster variables of } \mathcal{R}(C_w)\} \subseteq \{\rho_{Z} \in S^* \mid Z \text{ is indecomposable and rigid}\},
\]
\[
\{\text{cluster monomials of } \mathcal{R}(C_w)\} \subseteq \{\rho_{Z} \in S^* \mid Z \text{ is rigid}\}.
\]
Combining Theorems 8.1, 7.6 and 8.2 we obtain a partial converse of Theorem 8.1.

**Theorem 8.3.** The cluster variables in \(\mathcal{R}(C_w)\) are prime, and they are primitive elements of \(S^*\).

**Conjecture 8.4.** If \(\rho_{Z} \in S^*\) is indecomposable and rigid, then \(\rho_{Z}\) is prime in \(U(\mathfrak{n})^*_{\text{gr}}\).
8.2. Monoidal categorifications of cluster algebras. Let $\mathcal{C}$ be an abelian tensor category with unit object $I$. We assume that $\mathcal{C}$ is a Krull-Schmidt category, and that all objects in $\mathcal{C}$ are of finite length. Let $\mathcal{M}(\mathcal{C}) := K_0(\mathcal{C})$ be the Grothendieck ring of $\mathcal{C}$. The class of an object $M \in \mathcal{C}$ is denoted by $[M]$. The addition in $\mathcal{M}(\mathcal{C})$ is given by $[M] + [N] := [M \oplus N]$ and the multiplication is defined by $[M][N] := [M \otimes N]$. We assume that $[M \otimes N] = [N \otimes M]$.

The concept of a monoidal categorification of a cluster algebra was introduced in [HL]. Combining Proposition 8.5 with Theorem 3.1 we get the following result.

A monoidal categorification of a cluster algebra $\mathcal{A}(x, B)$ is an algebra isomorphism

$$\Phi : \mathcal{A}(x, B) \to \mathcal{M}_K(\mathcal{C}),$$

where $\mathcal{C}$ is a tensor category as above, such that each cluster monomial $y = y_1^{a_1} \cdots y_m^{a_m}$ of $\mathcal{A}(x, B)$ is mapped to a class $[S_y]$ of some simple object $S_y \in \mathcal{C}$. In particular, we have

$$[S_y] = [S_{y_1}]^{a_1} \cdots [S_{y_m}]^{a_m} = [S_{y_1}^{\otimes a_1} \otimes \cdots \otimes S_{y_m}^{\otimes a_m}].$$

For an object $M \in \mathcal{C}$ let $x_M$ be the element in $\mathcal{A}(x, B)$ with $\Phi(x_M) = [M]$.

The concept of a monoidal categorification of a cluster algebra was introduced in [HL] Definition 2.1. But note that our definition uses weaker conditions than in [HL].

An object $M \in \mathcal{C}$ is called invertible if $[M]$ is invertible in $\mathcal{M}_K(\mathcal{C})$. An object $M \in \mathcal{C}$ is primitive if there are no non-invertible objects $M_1$ and $M_2$ in $\mathcal{C}$ with $M \cong M_1 \otimes M_2$.

**Proposition 8.5.** Let $\Phi : \mathcal{A}(x, B) \to \mathcal{M}_K(\mathcal{C})$ be a monoidal categorification of a cluster algebra $\mathcal{A}(x, B)$. Then the following hold:

(i) The invertible elements in $\mathcal{M}_K(\mathcal{C})$ are

$$\mathcal{M}_K(\mathcal{C})^\times = \{ \lambda |I| | S_{x_1}^{a_1} \otimes \cdots \otimes S_{x_p}^{a_p} \mid \lambda \in K^\times, a_i \in \mathbb{Z} \}.$$

(ii) Let $M$ be an object in $\mathcal{C}$ such that the element $x_M$ is irreducible in $\mathcal{A}(x, B)$. Then $M$ is primitive.

**Proof.** Part (i) follows directly from Theorem 2.2. To prove (ii), assume that $M$ is not primitive. Thus there are non-invertible objects $M_1$ and $M_2$ in $\mathcal{C}$ with $M \cong M_1 \otimes M_2$. Thus in $\mathcal{M}_K(\mathcal{C})$ we have $[M] = [M_1][M_2]$. Since $\Phi$ is an algebra isomorphism, we get $x_M = x_{M_1}x_{M_2}$ with $x_{M_1}$ and $x_{M_2}$ non-invertible in $\mathcal{A}(x, B)$. Since $x_M$ is irreducible, we have a contradiction.

Combining Proposition 8.5 with Theorem 3.1 we get the following result.

**Documenta Mathematica** 18 (2013) 249–274
Corollary 8.6. Let $\Phi : A(x, B) \to \mathcal{M}_K(C)$ be a monoidal categorification of a cluster algebra $A(x, B)$. For each cluster variable $y$ of $A(x, B)$, the simple object $S_y$ is primitive.

Examples of monoidal categorifications of cluster algebras can be found in [HL][NI], see also [Le].

Acknowledgements. We thank Giovanni Cerulli Irelli, Sergey Fomin, Daniel Labardini Fragoso, Philipp Lampe and Andrei Zelevinsky for helpful discussions. We thank Giovanni Cerulli Irelli for carefully reading several preliminary versions of this article. The first author likes to thank the Max-Planck Institute for Mathematics in Bonn for a one year research stay in 2010/2011. The third author thanks the Sonderforschungsbereich/Transregio SFB 45 for financial support, and all three authors thank the Hausdorff Institute for Mathematics in Bonn for support and hospitality.

Large Parallel Volumes of Finite
and Compact Sets in d-Dimensional Euclidean Space

Jürgen Kampf and Markus Kiderlen

Received: January 10, 2012
Revised: June 18, 2012
Communicated by Lars Hesselholt

Abstract. The \( r \)-parallel volume \( V(C_r) \) of a compact subset \( C \) in
\( d \)-dimensional Euclidean space is the volume of the set \( C_r \) of all points
of Euclidean distance at most \( r > 0 \) from \( C \). According to Steiner’s
formula, \( V(C_r) \) is a polynomial in \( r \) when \( C \) is convex. For finite
sets \( C \) satisfying a certain geometric condition, a Laurent expansion
of \( V(C_r) \) for large \( r \) is obtained. The dependence of the coefficients
on the geometry of \( C \) is explicitly given by so-called intrinsic power
volumes of \( C \). In the planar case such an expansion holds for all finite
sets \( C \). Finally, when \( C \) is a compact set in arbitrary dimension, it is
shown that the difference of large \( r \)-parallel volumes of \( C \) and of its
convex hull behaves like \( cr^{d-3} \), where \( c \) is an intrinsic power volume
of \( C \).

2000 Mathematics Subject Classification: Primary 52A39; Secondary

Keywords and Phrases: Large parallel sets, Laurent expansion of par-
allel volume, Steiner formula, intrinsic power volume.

1 Introduction

In 1840, Jakob Steiner [10] showed that the \( r \)-parallel volume of certain compact
convex sets in \( \mathbb{R}^d \) are polynomials in \( r \geq 0 \) when \( d = 2 \) or \( d = 3 \). The
generalization to arbitrary dimensions is now known as the Steiner formula

\[
V_d(C_r) = \sum_{i=0}^{d} \kappa_i V_{d-i}(C)r^i, \quad r \geq 0.
\]

Both authors were supported by the Villum Foundation in the framework of the Centre
for Stochastic Geometry and Advanced Bioimaging, CSGB.
Here $C$ is any compact convex subset of $\mathbb{R}^d$, $C_r$ is the (outer) $r$-parallel set of $C$ consisting of all points of distance at most $r$ from $C$, $V_d$ is the Lebesgue measure, $\kappa_i$ denotes the volume of the $i$-dimensional Euclidean unit ball and $V_i(C)$ are the intrinsic volumes of $C$, which are defined by this relation. A possible proof of (1) uses the fact that the intrinsic volumes can be given explicitly in the case where the set $C$ is a convex polytope $P$:

$$V_i(P) = \sum_{F \in \mathcal{F}_i(P)} \gamma(F, P)V_i(F), \quad (2)$$

$i = 0, \ldots, d$. Here $\mathcal{F}_i(P)$ is the family of $i$-dimensional faces of $P$ and $\gamma(F, P)$ is the outer angle of $P$ at $F$ defined in Equation (13) below. There are numerous generalizations of the Steiner formula, for instance local versions [8, Chapter 4] and even Steiner-type results for arbitrary closed sets $C$; see [3]. Often, Steiner-type formulas are only valid for sufficiently small $r$, e.g. in the case of sets of positive reach [1]. In the present work we focus on $r$-parallel volumes for large $r$ and determine a Laurent series expansion or at least its leading coefficients. We discuss mainly the parallel volume of finite sets, which turns out to be already nontrivial, but Theorem 2, below, deals with compact sets $C \subseteq \mathbb{R}^d$. A first result for large parallel volumes has been obtained in [4] for compact sets $C \subseteq \mathbb{R}^d$, where it is shown that the volume of $C_r$ is close to the volume of its convex hull $\text{conv} C_r = (\text{conv} C)_r$. In fact, there is a constant $c = c(C)$ such that

$$0 \leq V_d(\text{conv} C_r) - V_d(C_r) \leq cr^{d-3} \quad (3)$$

for all sufficiently large $r$. In [4] an example set $C$ was given where this volume difference behaves like $r^{d-3}$, so the exponent here is best possible. Independently, a weaker version of (3) was shown in [7, Lemma 2], where $C$ was assumed to be an at most two-dimensional subset of the set $[0,1]^d$, $d \geq 3$, and the volume difference was shown to converge to zero faster than $r^{d-2}$. In [7] this was used to obtain an (incomplete) collection of asymptotic Miles-type formulas for the specific intrinsic volumes of stationary digitized Boolean models of balls. It was the original motivation for the present research to complete and generalize these results. One might even ask for similar asymptotic formulas for the specific intrinsic volumes of digitized standard random sets. (Standard random sets are stationary, a.s. locally polyconvex random sets, satisfying a certain integrability condition; see [9, Definition 9.2.1]). While the Boolean model case only requires (truncated) Laurent expansions for the volume of the set $C_r$, being the Minkowski sum of $C$ with the $r$-scaled Euclidean unit ball $B^d$, results for general standard random sets would require such expansions for the volume of the Minkowski sum of $C$ with an arbitrary $r$-scaled polyconvex set. In [6, Corollary 2.2] the first two leading coefficients of such a Laurent expansion are determined and [6, §5] discusses its application to the theory of random sets, including the calculation of the one-sided derivative of the contact distribution function at zero. However, higher order expansions in this general setting appear not to be known.

Documenta Mathematica 18 (2013) 275–295
Other applications of our expansions appear to be in reach. For example, in [4] formula (3) was used to examine the expected value of the parallel volume of Brownian paths, when the time is small, and to relate analytical properties of \( r \mapsto W(rK) \) to geometric properties of \( K \), where \( W \) denotes the Wills functional and \( K \) is a fixed compact set.

In the next section, the main results will be stated starting with the definition of functionals of finite subsets of \( \mathbb{R}^d \) capturing all geometric properties that are relevant when considering large parallel volumes. An optimal lower bound for the constant \( c \) in (3) will be given in Theorem 2. For finite sets \( C \), we obtain an explicit Laurent expansion in the case \( d = 2 \) in Proposition 1 and, under an additional condition on \( C \), in Theorem 5 for all \( d \geq 2 \). Section 3 provides proofs of the main results and discusses in particular the properties of the coefficients in the Laurent expansion.

2 Main results

The \( r \)-parallel volumes of one-dimensional compact sets are trivially affine functions for sufficiently large \( r \). We therefore assume \( d \geq 2 \) throughout the following. In the spirit of (2) define

\[
V_{i}^{(m)}(C) = \sum_{F \in \mathcal{F}_{i}(\text{conv} C)} \gamma(F, \text{conv} C) \int_{F} \frac{d(C \cap F, x)^{m-i}}{m!} \, dx,
\]

where \( i = 0, \ldots, d, m \geq i \), and \( C \) is a finite subset of \( \mathbb{R}^d \). We call the functionals \( V_{i}^{(m)} \) the intrinsic power volumes. Here, integration is understood with respect to \( i \)-dimensional Lebesgue measure in the affine hull of \( F \), and \( d(C \cap F, x) \) is the smallest Euclidean distance between \( x \) and a point in \( C \cap F \). Due to (2), we have

\[
V_{i}^{(i)}(C) = V_{i}(\text{conv} C)
\]

for all \( i = 0, \ldots, d \). The functionals \( V_{i}^{(m)} \), defined on the family of finite subsets of \( \mathbb{R}^d \), share many properties with usual intrinsic volumes (see Lemma 9) and are in particular independent of the dimension of the embedding space. The functional \( V_{i}^{(m)}(C) \), where the sum in (4) extends over all edges of \( \text{conv} C \), is given more explicitly in (17). In particular, if \( C \) is the set of vertices of a convex polytope,

\[
V_{i}^{(m)}(C) = \frac{1}{m!} \sum_{F \in \mathcal{F}_{i}(\text{conv} C)} \gamma(F, \text{conv} C) V_{i}^{m}(F)
\]

\( m \geq 1 \). In the case of planar finite sets, these (and the classical intrinsic volumes) are the only intrinsic power volumes that occur in a Laurent expansion of large parallel volumes.

Documenta Mathematica 18 (2013) 275–295
Proposition 1. Let $C \subseteq \mathbb{R}^2$ be a finite set and put $K = \text{conv} \ C$. Then

$$V_2(K_r) - V_2(C_r) = 2 \sum_{n=1}^{\infty} \frac{(2n-3)!!}{(2n)!!} V_1^{(2n+1)}(C) r^{-(2n-1)}$$

for all sufficiently large $r$. (The definition of the double factorial $n!!$ is recalled in Equation (12) below.)

Proposition 1 and Corollary 6 follow directly from Theorem 5 below. All other results in this section will be shown in Section 3. The leading coefficient of the Laurent expansion in Proposition 1 depends on $C$ through the intrinsic power volume $V_1^{(3)}(C)$. An analogue statement holds when $C$ is only assumed to be compact, and in all dimensions $d \geq 2$. To define $V_1^{(m)}(C)$, $m \geq 1$, also for compact $C \subseteq \mathbb{R}^d$, we choose for any $x \in \mathbb{R}^d$ two points $p_x^C$ and $q_x^C$ in $C$ with $x$ in the line segment $[p_x^C, q_x^C]$ and $C \cap [p_x^C, q_x^C] = \{p_x^C, q_x^C\}$, whenever such points exist and are unique up to permutation. Otherwise we put $p_x^C = q_x^C = x$. We then define

$$V_1^{(m)}(C) = \frac{1}{\kappa_{d-1}} \int_{\mathbb{R}^d} d\{p_x^C, q_x^C\} dx^{m-1} C_1(\text{conv} C, dx),$$

where $C_1(\text{conv} C, \cdot)$ is the first curvature measure of $\text{conv} C$. If $C$ is finite, then the definitions (4) and (6) coincide as will be shown in Remark 7.

Theorem 2. If $K$ is the convex hull of a compact set $C \subseteq \mathbb{R}^d$, then

$$\lim_{r \to \infty} \frac{V_d(K_r) - V_d(C_r)}{r^{d-3}} = \frac{\omega_{d-1}}{2} V_1^{(3)}(C).$$

Here $\omega_i$ is the surface area of the $(i-1)$-dimensional unit sphere in $\mathbb{R}^i$.

A natural question is whether the speed of convergence in Theorem 2 can be determined: is there an $\alpha > 0$ such that, for any compact $C \subseteq \mathbb{R}^d$, there is a constant $c = c(C)$ with

$$\left| \frac{V_d(K_r) - V_d(C_r)}{r^{d-3}} - \frac{\omega_{d-1}}{2} V_1^{(3)}(C) \right| \leq cr^{-\alpha}$$

for all sufficiently large $r$? The following proposition (with $f(r) = r^{-\alpha/2}$) shows that, already in $\mathbb{R}^2$, such a stability result cannot hold.

Proposition 3. Let $f : (0, \infty) \to (0, \infty)$ be a continuous bijective map with $\lim_{r \to \infty} f(r) = 0$. Then there is a compact set $C \subseteq \mathbb{R}^2$ and a number $c > 0$ such that

$$cf(r) \leq \left| \frac{V_2(K_r) - V_2(C_r)}{r^{-1}} - V_1^{(3)}(C) \right|$$

for all sufficiently large $r$. As usual, we have put $K = \text{conv} C$. 

Documenta Mathematica 18 (2013) 275–295
However, if the class of compact sets is replaced by the smaller class of all finite sets, a stability result with $\alpha = 1$ can be obtained. (That this speed of convergence is optimal for this class when $d \geq 3$ follows from Theorem 5 below.)

**Theorem 4.** Let $C \subseteq \mathbb{R}^d$ be finite and put $K = \text{conv} C$. Then there is a constant $c = c(C)$ such that

$$\left| \frac{V_d(K_r) - V_d(C_r)}{r^{d-3}} - \frac{\omega_{d-1}}{2} V_1^{(3)}(C) \right| \leq \frac{c}{r},$$

for sufficiently large $r$.

In the remainder of this section, $C$ will always be a finite subset of $\mathbb{R}^d$. Under the following condition on the facets (these are the $(d-1)$-dimensional faces) of $\text{conv} C$, we can also obtain a Laurent series expansion of infinite order in higher dimensions, generalizing Proposition 1.

**Condition (A).** For all facets $G$ of the polytope $K = \text{conv} C$ and all faces $F$ of $G$ we have

$$d(C \cap F, x) = d(C \cap G, x) \quad \text{for all } x \in F. \quad (9)$$

Clearly (9) holds whenever $F$ is a singleton or $F = G$. Hence Condition (A) must only be checked for faces $F$ of dimension between 1 and $d - 2$, and is in particular satisfied for all finite sets $C$ in $\mathbb{R}^2$. In $\mathbb{R}^3$, only edges $F \in \mathcal{F}_1(K)$ must be considered. In particular, if $C$ is the vertex set of a simplicial polytope in $\mathbb{R}^3$, Condition (A) is violated if and only if at least one facet of $\text{conv} C$ is a triangle with a strictly obtuse angle.

For instance, Condition (A) is fulfilled if $C \subseteq \mathbb{R}^d$ is the set of vertices of a rectangular cuboid. If $C$ is the set of the vertices of the standard simplex

$$S_d = \{(x_1, \ldots, x_d) \in \mathbb{R}^d : \sum_{i=1}^d x_i \leq 1, x_1, \ldots, x_d \geq 0 \}$$

in $\mathbb{R}^d$, Condition (A) is satisfied if and only if $d \in \{2, 3\}$. This can be shown as follows. We have already seen that Condition (A) is trivially fulfilled when $d = 2$, and it also holds for $d = 3$ as the triangles forming the facets of $S_3$ do not contain a strictly obtuse angle. For $d \geq 4$ the point $x = (1/3, 1/3, 1/3, 0, \ldots, 0) \in \mathbb{R}^d$ is contained in the face

$$F = \{(y_1, y_2, y_3, 0, \ldots, 0) \in \mathbb{R}^d : \sum_{i=1}^3 y_i = 1, y_1, y_2, y_3 \geq 0 \}$$

of the facet $G = S_{d-1} \times \{0\}$. Hence (9) is violated, as

$$d(C \cap F, x) = \sqrt{\frac{2}{3}} > \sqrt{\frac{1}{3}} = \|x - o\| = d(C \cap G, x).$$
If \( C \subseteq \mathbb{R}^d \) satisfies Condition (A), a Laurent expansion for large parallel volumes with explicit coefficients can be shown.

**Theorem 5.** Let \( K \) be the convex hull of a finite set \( C \subseteq \mathbb{R}^d \) that satisfies Condition (A). Then

\[
V_d(K_r) - V_d(C_r) = \sum_{n=3-d}^{\infty} a_n(C)r^{-n}
\]

for all sufficiently large \( r \) with coefficients

\[
a_n(C) = \min_{2(n+d-i)}(d-1,n+d-2) \left(\frac{-1}{(n+d-i)/2}\right) \left(\frac{-1}{n+2}\right) \kappa_{d-(n+2)}V_i^{(n+2)}(C)
\]

which vanish for all even positive \( n \).

As Condition (A) is satisfied for all planar finite sets, Proposition 1 is a direct consequence of Theorem 5. Indeed, in the case when \( n > 0 \) is odd and \( d = 2 \) the sum in the definition of \( a_n(C) \) consists only of one summand, namely

\[
a_n(C) = \left(\frac{-1}{n+3/2}\right) \kappa_2V_1^{(n+2)}(C) = 2 \frac{(n-2)!!}{(n+1)!!} V_1^{(n+2)}(C).
\]

Also for \( d = 3 \) the representation in Theorem 5 simplifies considerably. We get similarly as above

\[
a_0(C) = \left(\frac{-1}{1}\right) \kappa_2V_1^{(3)}(C) = \pi V_1^{(3)}(C),
\]

and

\[
a_n(C) = \left(\frac{-1}{n+3/2}\right) \kappa_2V_2^{(n+3)}(C) = 2 \frac{(n-2)!!}{(n+1)!!} V_2^{(n+3)}(C)
\]

for positive odd \( n \).

**Corollary 6.** Let \( K \) be the convex hull of a finite set \( C \subseteq \mathbb{R}^3 \) that satisfies Condition (A). Then, for all sufficient large \( r \),

\[
V_3(K_r) - V_3(C_r) = \pi V_1^{(3)}(C) + 2 \sum_{n=1}^{\infty} \frac{(2n-3)!!}{(2n)!!} V_2^{(2n+2)}(C) r^{-(2n-1)}.
\]

This section concludes by an example where Corollary 6 is applied to the vertex set

\[
C^d = \text{vert}([0,1]^d) = \bigcup_{F \in \mathcal{F}_d([0,1]^d)} F
\]
of the unit cube $[0,1]^d \subseteq \mathbb{R}^d$ for $d = 3$. It will be shown in Subsection 3.6 below, that (10) then becomes

$$V_3([0,1]^3) - V_3(C_r^3) = \frac{\pi}{4} + \sum_{n=1}^{\infty} b_n r^{-(2n-1)}$$

with

$$b_n = \frac{6}{(2n+1)(2n-1)(n+1)4^n} \sum_{i=0}^{n} \frac{(2i-1)!!}{i!}.$$ 

3 Proofs and auxiliary results

3.1 Notations and the intrinsic power volumes

The following subsection summarizes the notation and discusses basic properties of the intrinsic power volumes. For the reader’s convenience we repeat the most important concepts already named in the previous sections.

The Euclidean norm in $\mathbb{R}^d$ is denoted by $\| \cdot \|$, the closed Euclidean unit ball by $B^d$ and its boundary, the $(d-1)$-dimensional unit sphere by $S^{d-1}$. We write $A^C$, diam $A$, bd $A$, and relint $A$ for the complement, the diameter, the topological boundary, and the relative interior of a set $A \subseteq \mathbb{R}^d$, respectively. Let $d(A,x) = \inf_{y \in A} \|x-y\|$ be the distance of $x \in \mathbb{R}^d$ to $A \subseteq \mathbb{R}^d$. Let $[x,y]$ be the line segment with endpoints $x,y \in \mathbb{R}^d$. We denote the $m$-dimensional Hausdorff measure by $\mathcal{H}^m$ and use the volume of the Euclidean unit ball $\kappa_d = \mathcal{H}^d(B^d)$ and the surface area of the $(d-1)$-dimensional unit sphere $\omega_d = \mathcal{H}^{d-1}(S^{d-1})$. Often, we will write $V_d = \mathcal{H}^d$ for the usual Lebesgue measure. The double factorial of an integer $n \geq -1$ is defined to be

$$n!! = \begin{cases} n \cdot (n-2) \cdots 2, & \text{if } n > 0 \text{ is even}, \\ n \cdot (n-2) \cdots 1, & \text{if } n > 0 \text{ is odd}, \end{cases}$$

and the usual convention $(-1)!! = 0!! = 1$.

We recall some basic notions from convex geometry; see [8] for details. A convex body is a nonempty compact convex set in $\mathbb{R}^d$. For a convex body $K$ let $p(K,x)$ be the metric projection of $x \in \mathbb{R}^d$ onto $K$, that is the point in $K$ closest to $x$. Then $d(K,x) = \|x-p(K,x)\|$ is the distance between $x$ and $K$. If $x \not\in K$,

$$u(K,x) = \frac{x-p(K,x)}{d(K,x)} \in S^{d-1}$$

is the negative projection direction. A convex subset $F$ of a convex body $K$ is called face of $K$ if for any two points $x,y \in K$ with $x,y \in F$ we have $x,y \in F$. Let $\mathcal{F}_i(K)$ be the family of all $i$-dimensional faces of $K$, $i = 0, \ldots, d$. We denote the normal cone of $K$ at $F \in \mathcal{F}_i(K)$ by $N(K,F)$ and put $n(K,F) =$
Then \( n(K, F) = \{ u(K, x) \in S^{d-1} : x \notin K, p(K, x) \in \text{relint } F \} \).

For a polytope \( K \)

\[
\gamma(F, K) = \frac{\mathcal{H}^{d-i-1}(n(K, F))}{\omega_{d-i}}
\]

is the exterior angle of \( K \) at \( F \in \mathcal{F}(K) \), \( i = 0, \ldots, d-1 \). For completeness we set \( \gamma(K, K) = 1 \) if \( K \) is full-dimensional. We recall that the support measures \( \Theta_0(K, \cdot), \ldots, \Theta_{d-1}(K, \cdot) \) of \( K \) are the measures on \( \mathbb{R}^d \times S^{d-1} \) satisfying

\[
\mathcal{H}^d(\{ x \in \mathbb{R}^d \setminus K : d(K, x) \leq r, (p(K, x), u(K, x)) \in \eta \}) = \sum_{m=0}^{d-1} \binom{d-1}{m} r^{d-m} \omega_d \Theta_m(K, \eta)
\]

for all \( r \geq 0 \) and all Borel sets \( \eta \subseteq \mathbb{R}^d \times S^{d-1} \). More generally, for any measurable function \( f \geq 0 \) on \( \mathbb{R}^d \) we have

\[
\int_{\mathbb{R}^d \setminus K} f(x) \, dx = \sum_{m=0}^{d-1} \binom{d-1}{m} \int_{\mathbb{R}^d} \int_0^\infty f(x + su) \times
\]

\[
\times s^{d-m-1} \, ds \, \Theta_m(K, d(x, u)).
\]

The support measures are concentrated on the (generalized) normal bundle

\[
\mathcal{N}(K) = \{(p(K, y), u(K, y)) : y \notin K \} \subseteq (\text{bd } K) \times S^{d-1}.
\]

Their total mass is

\[
\Theta_m(K, \mathbb{R}^d \times S^{d-1}) = \omega_d \omega_m \binom{d-1}{m}^{-1} V_m(K).
\]

The area measures of \( K \) are the projections of the support measures to their second component:

\[
S_m(K, \omega) = \Theta_m(K, \mathbb{R}^d \times \omega)
\]

where \( \omega \) is a Borel set in \( S^{d-1} \). The curvature measures are their projections on the first component given by

\[
C_m(K, \beta) = \Theta_m(K, \beta \times S^{d-1})
\]

for Borel sets \( \beta \subseteq \mathbb{R}^d \). If \( K \) is a polytope, then

\[
\binom{d-1}{m} \Theta_m(K, \eta) = \sum_{F \in \mathcal{F}(K)} \int_F \int_{n(K, F)} 1_\eta(x, u) \, d\mathcal{H}^{d-m-1}(u) \, d\mathcal{H}^m(x)
\]

for any Borel set \( \eta \subseteq \mathbb{R}^d \times S^{d-1} \); see [8, (4.2.2)].
Remark 7. If $C$ is finite, then (16) implies
\[ C_1(\text{conv } C, \cdot) = \kappa_{d-1} \sum_{F \in F_1(\text{conv } C)} \gamma(F, \text{conv } C) \mathcal{H}^1(F \cap \cdot), \]
and thus, (6) coincides with the definition (4) when $i = 1$.

For a convex body $K \subseteq \mathbb{R}^d$ we call
\[ F_K(u) = \{ x \in K : \langle x, u \rangle = h_K(u) \} \]
the support set of $K$ in direction $u \in S^{d-1}$, where $h_K : S^{d-1} \to \mathbb{R}$ is the support function of $K$ and $\langle \cdot, \cdot \rangle$ denotes the Euclidean scalar product.

Lemma 8. Let $K \subseteq \mathbb{R}^d$ be a convex body and $m \in \{0, \ldots, d-2\}$. Set
\[ A_m = \{ u \in S^{d-1} : \dim F_K(u) \geq m + 1 \}. \]
Then $S_m(K, A_m) = 0$.

Proof. As a straight-forward generalization of [8, Theorem 2.2.9], we obtain
\[ \mathcal{H}^{d-m-1}(A_m) = 0. \]
By [8, Theorem 4.6.5] there is a constant $a$ such that
\[ S_m(K, \omega) \leq a \mathcal{H}^{d-m-1}(\omega) \]
for each $(\mathcal{H}^{d-m-1}, d-m-1)$-rectifiable set $\omega \subseteq S^{d-1}$, where we just want to mention that zero sets are always rectifiable and refer to [2, 3.2.14] for a complete definition. So, $S_m(K, A_m) = 0$.

We now summarize properties of the intrinsic power volumes as functionals on the family $\mathcal{E}$ of finite subsets $C$ of $\mathbb{R}^d$. In order to get a simplified expression for $V_i^{(m)}(C), m \geq 1$, we define the set
\[ F_1^*(C) = \{ [x,y] : x \neq y, [x,y] \cap C = \{ x,y \}, \]
there is $e \in F_1(\text{conv } C)$ with $[x,y] \subseteq e \}
of all refined edges of $\text{conv } C$, where every edge in $F_1(\text{conv } C)$ is partitioned into line segments such that exactly their endpoints are in $C$. Note that if $C = F_0(K)$ for a convex polytope $K$, then $F_1^*(C) = F_1(\text{conv } C)$, but in general this does not hold. For $C \in E$ and $e \in F_1^*(C)$ we put $N(\text{conv } C, e) = N(\text{conv } C, \tilde{e})$ and $\gamma(e, \text{conv } C) = \gamma(\tilde{e}, \text{conv } C)$, where $\tilde{e}$ is the unique edge of $\text{conv } C$ with $e \subseteq \tilde{e}$.

Lemma 9 (Properties of $V_i^{(m)}$). Let $i = 1, \ldots, d$, and $m \geq i$ be given.

(a) $V_i^{(i)}(C) = V_i(\text{conv } C)$ for any $C \in \mathcal{E}$. 

Documenta Mathematica 18 (2013) 275–295
(b) $V^{(m)}_i$ is homogeneous of degree $m$:

$$V^{(m)}_i(\alpha C) = \alpha^m V^{(m)}_i(C)$$

for all $\alpha \geq 0$ and all $C \in \mathcal{E}$.

(c) $V^{(m)}_i$ is motion invariant.

(d) $V^{(m)}_i$ is independent of the embedding space: Let $C$ be a finite set in $\mathbb{R}^{d'} \subseteq \mathbb{R}^d$ for some $d' < d$. Then $V^{(m)}_i(C)$ considered as a subset of $\mathbb{R}^{d'}$ coincides with $V^{(m)}_i(C)$ for the (lower-dimensional) subset $C$ of $\mathbb{R}^d$.

(e) Simplified expression for $V^{(m)}_1$: For finite $C \subseteq \mathbb{R}^d$ we have

$$V^{(m)}_1(C) = \sum_{F \in \mathcal{F}_1(\text{conv } C)} \gamma(F, \text{conv } C) V_1(F)^m.$$

Thus, $V^{(m)}_i$, as a functional on $\mathcal{E}$, has similar properties as the intrinsic volume on the family of convex bodies. However, in contrast to the latter, $V^{(m)}_i$ is in general not a valuation, i.e. it is not additive, and it is not continuous with respect to the Hausdorff metric. The properties (a)-(d) of Lemma 9 hold for arbitrary compact sets $C$ if $i = 1$.

3.2 Proof of Theorem 2

The proof of Theorem 2 is divided into a sequence of lemmas. Several times, the following analytical lemma will be needed. It can be shown using a Taylor expansion of order two.

**Lemma 10.** Let $n \in \mathbb{N}$, $0 \leq a \leq r$, and $f_n(r) = r^n - \sqrt{r^2 - a^2}$. Then

$$\frac{1}{2} a^2 r^{-1} \leq f_n(r) \leq \frac{1}{2} a^2 r^{-1} + \frac{\sqrt{2}}{4} a^4 r^{-3}, \quad \text{if } n = 1, \text{ and } a \leq \frac{r}{2},$$

$$\frac{3}{2} a^2 r - \frac{3\sqrt{2}}{8} a^4 r^{-1} \leq f_n(r) \leq \frac{3}{2} a^2 r, \quad \text{if } n = 3, \text{ and } a \leq \frac{r}{2},$$

$$\frac{n}{2} a^2 r^{n-2} - \frac{n(n-2)}{8} a^4 r^{n-4} \leq f_n(r) \leq \frac{n}{2} a^2 r^{n-2}, \quad \text{if } n \geq 4.$$

In short,

$$|f_n(r) - \frac{n}{2} a^2 r^{n-2}| \leq c_n a^4 r^{n-4} \quad (18)$$

where $c_2 = 0$ and $c_n = n(n-2)/8$ for $n \geq 4$. Inequality (18) also holds for $n = 1$ with $c_1 = \sqrt{2}/4$ and for $n = 3$ with $c_3 = 3\sqrt{2}/8$ if $0 \leq a \leq r/2$. In particular, the inequality $f_n(r) \leq na^2 r^{n-2}$, which is elementary for $n = 1$, holds for all $n$. 
For compact $C \subseteq \mathbb{R}^d$ we now show that the difference between the parallel volume of $K = \text{conv} \ C$ and the parallel volume of $C$ is approximately

$$I_C(r) = (d - 1) \int_{\mathbb{R}^d \times S^{d-1}} \int_0^\infty 1_{K \setminus C}(x + su) s^{d-2} ds \Theta_1(K, d(x, u)).$$

**Lemma 11.** Let $C \subseteq \mathbb{R}^d$ be a compact set and put $K = \text{conv} \ C$. Then there is a constant $c = c(C)$ with

$$0 \leq V_d(K_r) - V_d(C_r) - I_C(r) \leq c \cdot r^{d-4}$$

for all $r \geq \text{diam} \ C$.

**Proof.** Without loss of generality, we may assume that the diameter of $C$ is positive. If $x \in K_r \setminus C_r$, then due to $\text{ext} \ K := \bigcup_{F \in F_0(K)} F \subseteq C$, we have $p(K, x) / \notin \text{ext} \ K,$ (20) and an application of the Pythagorean theorem implies

$$d(K, x) > \sqrt{r^2 - (\text{diam} \ C)^2},$$

whenever $r \geq \text{diam} \ C$; see [5, Example 3.3 and Lemma 3.5]. Since $r \geq \text{diam} \ C$ implies $(K_r \setminus C_r) \cap K = 0$ and (20) together with Lemma 8 implies $\Theta_0(K, \{(p(K, x), u(K, x)) \mid x \in K_r \setminus C_r\}) = 0$, we get from (14) with $f = 1_{K_r \setminus C_r}$ that

$$V_d(K_r) - V_d(C_r) = V_d(K_r \setminus C_r)$$

$$= \sum_{m=1}^{d-1} \left( \frac{d-1}{m} \right) \int_{\mathbb{R}^d \times S^{d-1}} \int_0^\infty 1_{K_r \setminus C_r}(x + su) \times$$

$$\times s^{d-m-1} ds \Theta_m(K, d(x, u)).$$

(22)

The term on the right hand side of (22) corresponding to $m = 1$ is $I_C(r)$. We now consider the summands of the right hand side of (22) for which $m \geq 2$. For $d = 2$ no such summands exist. Since all these summands are non-negative for $d \geq 3$, the left inequality of the assertion is shown. The right inequality follows from the fact that – due to equations (21) and (15) and Lemma 10 – the right hand side of (22), without the summand for $m = 1$, is bounded from above by

$$\sum_{m=2}^{d-1} \left( \frac{d-1}{m} \right) \int_{\mathbb{R}^d \times S^{d-1}} \int_r^\infty s^{d-m-1} ds \Theta_m(K, d(x, u))$$

$$= \sum_{m=2}^{d-1} \omega_{d-m} \frac{1}{d-m} \left( r^{d-m} - (r^2 - (\text{diam} \ C)^2)^{(d-m)/2} \right) V_m(K)$$

$$\leq \sum_{m=2}^{d-1} \omega_{d-m}(\text{diam} \ C)^2 r^{d-m-2} V_m(K)$$

$$\leq cr^{d-4},$$

where $c = c(C)$.

**Documenta Mathematica 18 (2013) 275–295**
where \( c = \sum_{m=2}^{d-1} \omega_{d-m}(\text{diam } C)^{4-m} V_m(K) \).

An upper bound for \( I_C(r) \) is obtained easily.

**Lemma 12.** Let \( C \subseteq \mathbb{R}^d \) be a compact set and put \( K = \text{conv } C \). If \( r \geq 2(\text{diam } C) \), then

\[
I_C(r) \leq \frac{\omega_{d-1}}{2} V_1^{(3)}(C) r^{d-3}
\]

for \( d \geq 3 \) and

\[
I_C(r) \leq V_1^{(3)}(C) r^{-1} + \frac{\omega_2}{2} V_1^{(5)}(C) r^{-3}
\]

for \( d = 2 \).

**Proof.** Recall \( A_1 := \{ u \in S^{d-1} \mid \dim F_K(u) \geq 2 \} \). For any \( (x,u) \in ((bd K \setminus C) \times A_1) \cap N(K) \) the set \( F_K(u) \) is at most 1-dimensional due to \( x \notin A_1 \) and at least 1-dimensional due to \( x \notin C \). Thus we have \( p_x^C \neq x \) and \( q_x^C \neq x \), where \( p_x^C \) and \( q_x^C \) were defined before formula (6). Now

\[
1_{K \setminus C} (x+su) = 1_{\{ p_x^C \neq x \}} (x+su) \leq 1_{\{ p_x^C \neq x \}} (x+su)
\]

holds for all \((x,u) \in ((bd K \setminus C) \cap N(K) \) by Lemma 8. Setting \( a_x = d(\{ p_x^C \neq x \}, x) \), we get

\[
I_C(r) \leq (d-1) \int_{\mathbb{R}^d \times S^{d-1}} \int_0^\infty 1_{\{ p_x^C \neq x \}} (x+su) s^{d-2} ds \Theta_1(K, d(x,u))
\]

\[
= (d-1) \int_{\mathbb{R}^d \times S^{d-1}} \int_0^r \sqrt{r^2 - a_x^{d-1}} s^{d-2} ds \Theta_1(K, d(x,u))
\]

\[
= \int_{\mathbb{R}^d} \left( r^{d-1} - \sqrt{r^2 - a_x^{d-1}} \right) C_1(K, dx).
\]

Lemma 10 with \( n = d-1 \) and \( a = a_x \) yields

\[
I_C(r) \leq \frac{d-1}{2} \int_{\mathbb{R}^d} a_x^2 C_1(K, dx) r^{d-3}
\]

for \( d \geq 3 \), and

\[
I_C(r) \leq \frac{1}{2} \int_{\mathbb{R}^d} a_x^2 C_1(K, dx) r^{-1} + \frac{\omega_2}{2} \int_{\mathbb{R}^d} a_x^4 C_1(K, dx) r^{-3}
\]

for \( d = 2 \). In view of (6) this shows the assertion.

We now derive the corresponding asymptotic lower bound for \( I_C(r)^{-d/(d-3)} \).

**Lemma 13.** For any compact \( C \subseteq \mathbb{R}^d \) we have

\[
\liminf_{r \to \infty} \frac{I_C(r)}{r^{d-3}} \geq \frac{\omega_{d-1}}{2} V_1^{(3)}(C).
\]
Proof. Let $K$ be the convex hull of $C$. For $x \in \mathbb{R}^d$ set $\tau_x = (q^C_x - p^C_x) / \|q^C_x - p^C_x\|$ if $p^C_x \neq q^C_x$, and set $\tau_x = 0$, otherwise. The following arguments do not depend on the orientation of $\tau_x$. For $(x, u) \in \mathcal{N}(K)$, $\epsilon \geq 0$ and $\delta > 0$ we denote the indicator of the following event by $\zeta(x, u, \epsilon, \delta)$: for any $y \in C$ the implication

$$\langle x - y, u \rangle \leq \epsilon \implies \langle y, \tau_x \rangle < \langle p^C_x, \tau_x \rangle + \epsilon \text{ or } \langle y, \tau_x \rangle > \langle q^C_x, \tau_x \rangle - \delta$$

holds. Note that if $p^C_x = q^C_x$ (and in particular if $x \in C$), we have $\zeta(x, u, \epsilon, \delta) = 1$.

Fix $(x, u) \in \mathcal{N}(K)$ with $x \notin C$, and numbers $\delta > 0, \epsilon, s \geq 0$. Put

$$a_x = d((p^C_x, q^C_x), x) \leq \frac{\text{diam } C}{2}$$

and $r_x = \max\{(\text{diam } C)^2/(4\epsilon), (\text{diam } C)/2\}$. In order to find a lower bound for $I_C(r)$, we will first show the inequality

$$\zeta(x, u, \epsilon, \delta) \mathbf{1}_{\{\sqrt{r^2 - ((a_x - \delta)^+)^2} \leq s\}} \leq \mathbf{1}_{\{d(C, x + su) \geq r\}}, \quad (24)$$

for all $r \geq r_x$. So assume $\zeta(x, u, \epsilon, \delta) = 1$ and $\sqrt{r^2 - ((a_x - \delta)^+)^2} \leq s$. Let $y \in C$. If $\langle x - y, u \rangle \leq \epsilon$, then $\zeta(x, u, \epsilon, \delta) = 1$ implies

$$d(y, x + su)^2 \geq s^2 + \langle x - y, \tau_x \rangle^2 \geq s^2 + ((a_x - \delta)^+)^2 \geq r^2.$$ 

If $\langle x - y, u \rangle > \epsilon$, then

$$d(y, x + su)^2 \geq \langle x - y, u \rangle^2 + s^2 \geq \epsilon^2 + \sqrt{r^2 - ((a_x - \delta)^+)^2}^2 \geq r^2$$

for all $r \geq r_x$ by Lemma 10. So $d(C, x + su) \geq r$ for all $r \geq r_x$, which completes the proof of (24).

Now let $\epsilon, \delta > 0$. For all $r \geq r_x$ Lemma 8 and inequality (24) imply

$$I_C(r) = (d - 1) \int_{(bdK) \times A^C_1} \int_0^r \mathbf{1}_{\{d(C, x + su) \geq r\}} s^{d-2} ds \Theta_1(K, d(x, u))$$

$$\geq (d - 1) \int_{(bdK) \times A^C_1} \int_0^r \mathbf{1}_{\{d(C, x + su) \geq r\}} \zeta(x, u, \epsilon, \delta) s^{d-2} ds \Theta_1(K, d(x, u))$$

$$= \int_{(bdK) \times A^C_1} \zeta(x, u, \epsilon, \delta) \left(r^{d-1} - \sqrt{r^2 - ((a_x - \delta)^+)^2}^{d-1}\right) \Theta_1(K, d(x, u)).$$

Since

$$\lim_{r \to \infty} \frac{r^{d-1} - \sqrt{r^2 - ((a_x - \delta)^+)^2}^{d-1}}{r^{d-3}} = \frac{d-1}{2}((a_x - \delta)^+)$$

due to Lemma 10, Fatou’s lemma gives

$$\liminf_{r \to \infty} \frac{I_C(r)}{r^{d-3}} \geq \frac{d-1}{2} \int_{(bdK) \times A^C_1} \zeta(x, u, \epsilon, \delta) ((a_x - \delta)^+) \Theta_1(K, d(x, u)).$$
Now we first let $\epsilon \to 0$ using $\lim_{\epsilon \to 0} \zeta(x, u, \epsilon, \delta) = \zeta(x, u, 0, \delta)$, and the monotone convergence theorem. Since $\zeta(x, u, 0, \delta)((a_x - \delta)^+)^2 \leq (\text{diam } C)^2$, we can use the dominated convergence theorem to let $\delta \to 0$, and get

$$\lim_{r \to \infty} \inf_{r \to \infty} \frac{1}{r^{d-3}} \int_{(\text{bd } K) \times \mathcal{A}^C_1} \zeta(x, u, 0, \delta) a_x^2 \Theta_1(K, d(x, u)).$$

For all $(x, u) \in (\text{bd } K) \times \mathcal{A}^C_1$, we have $\lim_{\delta \to 0} \zeta(x, u, 0, \delta) = 1$, and (23) follows using (6) and Lemma 8.

Theorem 2 now follows directly from Lemmas 11, 12, and 13.

3.3 Proof of Proposition 3

Without loss of generality, may assume that $f(r) \geq \frac{1}{4}$ holds for all $r \in (0, \infty)$. Put $g : [0, 1] \to (-\infty, 0], x \mapsto -x/(6f^{-1}(x))$, and let $S = g(1) = 1$,

$$C = \{(x, g(x)) : x \in [0, 1]\} \cup \{(x, g(2 - x)) : x \in [1, 2]\} \cup \{(0, S), (2, S)\}$$

and

$$C^0 = \{(0, 0), (2, 0), (0, S), (2, S)\}.$$

For any $r \in \mathbb{R}$, large enough that $f(r) \leq 1/3$, we have $r \geq \frac{1}{f(r)} \geq 3$ and

$$V_2(C_r) - V_2(C_r^0) \geq \int_0^1 \left( \max\{y \in \mathbb{R} : (x, y) \in C_r\} - \max\{y \in \mathbb{R} : (x, y) \in C_r^0\} \right) dx$$

$$\geq \int_0^1 \left( \max\{y \in \mathbb{R} : \|\langle x, y \rangle - (f(r), g(f(r)))\| \leq r\} - \max\{y \in \mathbb{R} : (x, y) \in C_r^0\} \right) dx$$

$$= \int_0^1 \left( \sqrt{r^2 - (x - f(r))^2} + g(f(r)) - \sqrt{r^2 - x^2} \right) dx$$

$$\geq \int_0^1 \left( \frac{2xf(r) - f(r)^2}{2\sqrt{r^2 - (x - f(r))^2}} + g(f(r)) \right) dx$$

by using Lemma 10 with $r, a,$ and $n$ replaced by $\sqrt{r^2 - (x - f(r))^2}$, $\sqrt{2xf(r) - f(r)^2}$, and 1, respectively. Since $g(f(r)) = -\frac{f(r)}{6r}$, this integral can be estimated from below by

$$\int_0^1 \frac{2xf(r) - f(r)^2}{2r} - \frac{f(r)}{6r} dx = \frac{f(r)}{2r} - \frac{f(r)^2}{2r} - \frac{f(r)}{6r} \geq \frac{f(r)}{6r}.$$
Observing that $K = \text{conv} C = \text{conv} C^0$ and $V_1^{(3)}(C) = V_1^{(3)}(C^0)$ we conclude from Proposition 1 that there is a constant $c_1 \geq 0$ with

$$V_1^{(3)}(C) \frac{1}{r} - (V_2(K_r) - V_2(C_r))$$

$$= - (V_2((\text{conv} C^0)_r) - V_2(C^0_r)) + (V_2(C_r) - V_2(C^0_r))$$

$$\geq -\frac{c_1}{r^3} + \frac{f(r)}{6r}$$

$$\geq \frac{f(r)}{12r}$$

for all sufficiently large $r$. Hence

$$V_1^{(3)}(C) - \frac{V_2(K_r) - V_2(C_r)}{r^{-1}} \geq \frac{f(r)}{12}$$

for all sufficiently large $r$ and Proposition 3 is shown.

Remark 14. In order to show a statement analogous to Proposition 3 in higher dimensions, one can consider bodies of revolution.

3.4 Proof of Theorem 4

Theorem 4 is a consequence of Lemmas 11, 12 and the following result.

Lemma 15. For any finite set $C \subseteq \mathbb{R}^d$ there is a constant $c = c(C) > 0$ such that

$$I_C(r) \geq \frac{\omega_{d-1}}{2} V_1^{(3)}(C)r^{d-3} - cr^{d-4}$$

for all sufficiently large $r$.

Proof. We have

$$I_C(r) = (d - 1) \int_{(bd K) \times S^{d-1}} \int_0^r 1_{(C_r)}(x + su)s^{d-2}ds \Theta_1(K,d(x,u)).$$

As

$$1_{(C_r)}(x + su) = 1_{(p^C, q^C)}(x + su)(1 - 1_{(C \setminus (p^C, q^C))}, (x + su))$$

$$\geq 1_{(p^C, q^C)}(x + su)(1 - \sum_{y \in C} 1_{[0,r]}(\|x + su - y\|)),$$

and

$$1_{(p^C, q^C)}(x + su) = 1_{(\sqrt{r^2 - a^2} \to \infty)}(s)$$

(with $a_x = d((p^C_x, q^C_x), x))$, we get

$$I_C(r) \geq \int_{(bd K) \times S^{d-1}} \left( r^{d-1} - \sqrt{r^2 - a_x^2}^{d-1} \right) \Theta_1(K,d(x,u)) - \sum_{y \in C} J_C(r,y).$$

(26)
Here,

$$J_C(r,y) = (d-1) \int_{(bd\ K)\times S^{d-1}} \int_0^r \mathbf{1}_{(p\notin aF)}(x) \xi(x + sy) \times$$

$$\times \mathbf{1}_{[0,r]}(||x + sy - y||) s^{d-2} ds \Theta_1(K, d(x,y)).$$

(27)

By Lemma 16 below, $J_C(r,y) = O(r^{d-4})$ for all $y \in C$, as $r \to \infty$, and thus the second term on the right hand side of (26) is $O(r^{d-4})$. Lemma 10 with $n = d - 1$ and $a = a_d$ together with (6) shows that the first term on the right hand side of (26) is bounded from below by

$$\frac{\omega_{d-1}}{2} V_1^{(3)}(C) r^{d-3} - c_{d-1} \kappa_{d-1} V_1^{(5)}(C) r^{d-5}$$

for all sufficiently large $r$. Hence (25) follows from (26).

**Lemma 16.** Let $C \subseteq \mathbb{R}^d$ be finite and $y \in C$. Then there is a constant $c = c(C,y) > 0$ such that

$$J_C(r,y) \leq cr^{d-4}$$

for all sufficiently large $r$, where $J_C(r,y)$ is defined by (27).

**Proof.** From (27) and (16) we get

$$J_C(r,y) = \sum_{e \in \mathcal{E}_1(K)} \int_{n(K,e)} \int_0^r \int_0^{\eta_K} \zeta(x + sy) s^{d-2} ds dH^{d-2}(u) dH_1(x).$$

where $\zeta(z) = \mathbf{1}_{(relbd\ e)}(z) \mathbf{1}_{[0,r]}(||z - y||)$. Note that the relative boundary relbd\ e of e consists just of the two endpoints of e. Spherical coordinates in hyperplanes orthogonal to e and Fubini’s theorem give

$$J_C(r,y) = \sum_{e \in \mathcal{E}_1(K)} \int_{\mathbb{R}^d} \mathbf{1}_e(p(K,z)) \mathbf{1}_n(K,e)(u(K,z)) \zeta(z) dz.$$

(28)

Fix $e \in \mathcal{E}_1(K)$ and let $x_1$ and $x_2$ be its endpoints. We assume without loss of generality that e contains the origin. Let g be the affine hull of e and let L be the affine hull of e and y. We may assume $y \notin g$, since we cannot have $y \in \text{relint} e$ and we have $\mathbf{1}_e(p(K,z)) \mathbf{1}_{n(K,e)}(u(K,z)) \zeta(z) = 0$ for all $z \in \mathbb{R}^d$ if $y \in g \setminus \text{relint} e$. Let $H^+$ be the closed half space containing e in its boundary with normal vector $y - p(g,y)$, such that $y \notin H^+$. Finally let $V_y$ be the Voronoi cell of y with respect to the set $\{x_1, x_2, y\}$. The planar set

$$T = L \cap V_y \cap H^+ \cap (e + g^{-})$$

is either empty or a bounded triangle. For nonempty T let $\delta > 0$ be the maximal distance from a point of T to $\{x_1, x_2\}$. If $T = \emptyset$ put $\delta = 0$. If we can show that

$$\mathbf{1}_e(p(K,z)) \mathbf{1}_{n(K,e)}(u(K,z)) \zeta(z) \leq \mathbf{1}_T(z) |L| \mathbf{1}_{(\text{relbd} e)}(||z||)$$

(29)
holds for all $r > \delta$ and $z \in \mathbb{R}^d$, then
\[
\int_{\mathbb{R}^d} 1_e(p(K, z))1_{u(K, z)}(\zeta(z)) \, dz \\
\leq \int_{L^+} \int_{L} 1_{T(y_1)}1_{(\sqrt{r^2 - \delta^2}, r]}(\|y_2\|) \, dy_1 \, dy_2 \\
= V_2(T) \cdot \kappa_{d-2}(\sqrt{r^2 - \delta^2} - \delta^{d-2}) \\
\leq (d-2)\kappa_{d-2}V_2(T)\delta^2r^{d-4},
\]
for all $r > \delta$. The last inequality is evident in the case $d = 2$, and follows for $d \geq 3$ from Lemma 10 with $n = d - 2$ and $a = \delta$. Bounding all summands in (28) in such a way shows the assertion.

It remains to prove (29). Assume that the left hand side of (29) is one. Then $p(K, z) \in e$, $u(K, z) \in u(K, e)$, $\|z - x_1\| > r$, $\|z - x_2\| > r$, and $\|z - y\| \leq r$. The last three inequalities imply $z \in V_y$ and $z|L \in V_y|L = V_y \cap L$. The convexity of $K$ and $y \in K$ imply $\langle z - p(K, z), y - p(K, z) \rangle \leq 0$. Since both $z - p(K, z)$ and $y - p(g, y)$ are perpendicular to $g$, this gives $z \in H^+$. Finally,
\[
z \in e + N(K, e) \subseteq e + g^\perp
\]
gives $z|L \in T$. As $\|z|L^\perp\| \leq \|z - y\| \leq r$ and
\[
r^2 < d(x_1, x_2, z)^2 = d(x_1, x_2, z|L)^2 + d(z|L, z)^2 \leq \delta^2 + \|z|L^\perp\|^2,
\]
we have $\sqrt{r^2 - \delta^2} < \|z|L^\perp\| \leq r$, and (29) is shown.

### 3.5 Proof of Theorem 5

We first show a key observation: If Condition (A) holds, then, for sufficiently large $r$, the part of the difference set $K_r \setminus C_r$ that is projected on a face $F$ is independent of the points of $C$ outside $F$.

**Lemma 17.** Let $C \subseteq \mathbb{R}^d$ be a finite set satisfying Condition (A). If $K = \text{conv} C$, $m \in \{0, \ldots, d - 1\}$, and $F \in \mathcal{F}_m(K)$ then
\[
(K_r \setminus C_r) \cap (F + N(K, F)) = (F \setminus (C \cap F)_r) \cap (F + N(K, F)) \tag{30}
\]
for all sufficiently large $r$.

**Proof.** Since
\[
K_r \cap (F + N(K, F)) = F_r \cap (F + N(K, F))
\]
and $(C \cap F)_r \subseteq C_r$, the set on the left-hand side is contained in the set on the right-hand side. To show the opposite inclusion, let $V_y$ be the Voronoi cell of $y \in C$ with respect to $C$, let $S_y = V_y \cap (F + N(K, F))$ be the set of all the points in $V_y$ with metric projection in $F$, and define
\[
r_0 = \min\{r \geq 0 : S_y \subseteq (C \cap F)_r \text{ for all } y \in C \text{ with bounded } S_y\}.
\]
Let \( r > r_0 \) and assume

\[
x \in (F_r \setminus (C \cap F)_r) \cap (F + N(K, F)).
\]

Then, clearly, \( x \in K_r \). Moreover, we have \( \| x - y \| > r \) for all \( y \in C \cap F \). As \( \{ V_y : y \in C \} \) covers \( \mathbb{R}^d \), there is a \( y \in C \) with \( x \in V_y \cap (F + N(K, F)) = S_y \). The definition of \( r_0 \) and \( x \notin (C \cap F)_r \) imply that the closed convex set \( S_y \) is unbounded. Hence, there is a ray with direction \( \langle v, y \rangle \) contained in \( S_y \). It follows that \( v \in N(K, F) \) and, as the ray is contained in \( V_y \), that \( \langle y, v \rangle \geq h_K(v) \). Hence \( F \) and \( y \) are contained in a supporting hyperplane of \( K \) (with normal \( v \)), and thus they are contained in some facet \( G \) of \( K \). As \( x' = p(K, x) \in F \), Condition (A) implies that there is a point \( y' \in C \cap F \) with \( \| y - y' \| \geq \| x' \| \) and thus

\[
d(C, x)^2 = \| y - x \|^2 \geq \| y - y' \|^2 + \| x' - x \|^2 \\
\geq \| y' - x' \|^2 + \| x' - x \|^2 = \| y' - x \|^2 > r^2,
\]

where the first equality is due to \( x \in V_y \), the first inequality follows from \( \langle y, x - x' \rangle \leq \langle x', x - x' \rangle \) (see [8, Lemma 1.3.1]) and the last inequality is due to \( x \notin (C \cap F)_r \). Hence \( x \notin C_r \), which completes the proof of (30).

We now prove Theorem 5. Let \( C \subseteq \mathbb{R}^d \) be a finite set that satisfies Condition (A), and set \( K = \text{conv} \, C \). Assume \( r > \text{diam} \, C \). Due to (14) with \( f = 1_{K_r \setminus C_r} \), (20), and (16) we have

\[
V_d(K_r) - V_d(C_r) = \sum_{m=1}^{d-1} \sum_{F \in F_m(K)} I_{F,m}
\]

with

\[
I_{F,m} = \int_{F} \int_{n(K,F)} \int_{0}^{\infty} 1_{K \setminus C_f}(x + su)s^{d-m-1}ds \, dH^{d-m-1}(u) \, dH^m(x),
\]

\( m \in \{1, \ldots, d-1\}, F \in F_m(K) \). For all sufficiently large \( r \), Lemma 17 implies

\[
I_{F,m} = \int_{F} \int_{n(K,F)} \int_{0}^{\infty} 1_{F_r \setminus (C \cap F)_r}(x + su)s^{d-m-1}ds \, dH^{d-m-1}(u) \, dH^m(x)
\]

\[
= \int_{F} \int_{n(K,F)} \int_{0}^{\sqrt{r^2 - d(C \cap F; x)^2}} s^{d-m-1}ds \, dH^{d-m-1}(u) \, dH^m(x)
\]

\[
= \frac{\omega_{d-m}}{d-m} \gamma(F,K) \int_{F} \left( r^{d-m} - \sqrt{r^2 - d(C \cap F; x)^2} \right)^{d-m} \, dH^m(x).
\]

Put \( a_{F,x} = d(C \cap F, x) \). The binomial series

\[
r^{d-m} - \sqrt{r^2 - a_{F,x}^2} = r^{d-m} \sum_{k=1}^{\infty} (-1)^{k+1} \binom{(d-m)/2}{k} \left( \frac{a_{F,x}}{r} \right)^{2k}
\]

\[\text{Documenta Mathematica 18 (2013) 275–295}\]
converges absolutely as \( r > \text{diam} \, C \geq a_{F,x} \). Hence

\[
I_{F,m} = \sum_{k=1}^{\infty} (-1)^{k+1} \left( \frac{(d-m)/2}{k} \right)^{\kappa_{d-m} \gamma(F,K)} \int_{F} a_{F,x}^{2k} \, d\mathcal{H}^{m}(x) \, r^{d-m-2k} = \sum_{n \geq \frac{2}{d}} \sum_{m \leq 2(n+d-m)} (-1)^{(n+d-m+2)/2} \left( \frac{(d-m)/2}{n+d-m} \right) \times \\
\times \kappa_{d-m} \gamma(F,K) \int_{F} a_{F,x}^{n+d-m} \, d\mathcal{H}^{m}(x) \, r^{-n}.
\]

Substitution into (31) and definition (4) gives

\[
V_{d}(K_{r}) - V_{d}(C_{r}) = \sum_{m=1}^{d-1} \sum_{n \geq \frac{2}{d}} \sum_{m \leq 2(n+d-m)} (-1)^{(n+d-m+2)/2} \left( \frac{(d-m)/2}{n+d-m} \right) \times \\
\times \kappa_{d-m} V_{m(n+d)}(C) \, r^{-n} = \sum_{n=3-d}^{\infty} \sum_{m \geq 2(n+d-m)} (-1)^{(n+d-m+2)/2} \left( \frac{(d-m)/2}{n+d-m} \right) \times \\
\times \kappa_{d-m} V_{m(n+d)}(C) \, r^{-n}.
\]

If \( n \) is positive and even, the inner sum only involves integers \( m \) with the same parity as \( d \), and \( (d-m)/2 < (n+d-m)/2 \) are both integers implying \( (d-m)/2 = 0 \). Hence all coefficients of \( r^{-n} \) vanish for even \( n > 0 \).

This concludes the proof of Theorem 5.

### 3.6 The example of the unit cube.

We show (11). In arbitrary dimension \( d \) the number of \( i \)-dimensional faces of \([0,1]^{d}\) is

\[
\# \mathcal{F}_{i}([0,1]^{d}) = 2^{d-i} \binom{d}{d-i}.
\]

Using orthogonal projections and symmetry we get

\[
\gamma(F, [0,1]^{d}) = \gamma([0,1]^{d-1}) = (\# \mathcal{F}_{0}([0,1]^{d-1}))^{-1} = 2^{-(d-i)}
\]

for any \( F \in \mathcal{F}_{i}([0,1]^{d}) \), \( i = 0, \ldots, d-1 \). Thus definition (4) and a symmetry argument give

\[
V_{i}^{(m+i)}(C^{d}) = \binom{d}{d-i} \int_{[0,1]} d(C^{i}, x)^{m} dx \times \\
= 2^{i} \binom{d}{d-i} \int_{[0,1]} \|x\|^{m} dx \times \\
= 2^{-m} \binom{d}{d-i} \int_{[0,1]} \|x\|^{m} dx.
\]
This implies
\[ V_1^{(m+1)}(C^d) = \frac{d}{(m+1)2^m} \] (32)
for \( m \geq 0 \), and, introducing polar coordinates,
\[ V_2^{(m+2)}(C^d) = 2^{-m} \left( \frac{d}{d-2} \right) 2 \int_0^{\pi/4} \int_0^{1/\cos \varphi} \| r \cdot (\cos \varphi, \sin \varphi) \|^m r \, dr \, d\varphi \]
\[ = \frac{d(d-1)}{(m+2)2^m} \int_0^{\pi/4} \cos^{-(m+2)}(\varphi) \, d\varphi. \]

We put \( d_n := \int_0^{\pi/4} \cos^{-n}(\varphi) \, d\varphi \). Integrating \( \int_0^{\pi/4} \cos^{-(n+1)}(\varphi) \cos(\varphi) \, d\varphi \) by parts, we obtain the recurrence relation
\[ (n+1)d_{n+2} = 2^{n/2} + nd_n, \quad n \geq 0, \]
with starting value \( d_0 = \frac{\pi}{4} \). Induction gives
\[ d_{2m} = 2^{m-1} \frac{(m-1)!}{(2m-1)!!} \sum_{i=0}^{m-1} \frac{(2i-1)!!}{i!}, \]
and we arrive at
\[ V_2^{(2m+2)}(C^3) = \frac{3}{(m+1)4^m} d_{2m+2} \]
\[ = \frac{3(m!)}{(2m+1)!! (m+1)2^m} \sum_{i=0}^{m} \frac{(2i-1)!!}{i!}. \] (33)

As \( C^3 \) satisfies Condition (A), (11) follows by substituting (32) with \( d = 3 \), \( m = 2 \), and (33) into (10).

TRANSPORTATION-COST INEQUALITIES
ON PATH SPACE OVER MANIFOLDS WITH BOUNDARY

FENG-YU WANG

Received: May 9, 2011
Revised: October 11, 2011
Communicated by Friedrich Götze

ABSTRACT. Let \( L = \Delta + Z \) for a \( C^1 \) vector field \( Z \) on a complete Riemannian manifold possibly with a boundary. A number of transportation-cost inequalities on the path space for the (reflecting) \( L \)-diffusion process are proved to be equivalent to the curvature condition \( \text{Ric} - \nabla Z \geq -K \) and the convexity of the boundary (if exists). These inequalities are new even for manifolds without boundary, and are partly extended to non-convex manifolds by using a conformal change of metric which makes the boundary from non-convex to convex.

2010 Mathematics Subject Classification: 60J60, 58G60.
Keywords and Phrases: Transportation-cost inequality, curvature, second fundamental form, path space.

1 INTRODUCTION

In 1996 Talagrand [13] found that the \( L^2 \)-Wasserstein distance to the standard Guassian measure can be dominated by the square root of twice relative entropy. This inequality is called (Talagrand) transportation-cost inequality, and has been extended to distributions on finite- and infinite-dimensional spaces. In particular, this inequality was established on the path space of diffusion processes with respect to several different distances (i.e. cost functions); see e.g. [7] for the study on the Wiener space with the Cameron-Martin distance, [17, 15] on the path space of diffusions with the \( L^2 \)-distance, [18] on the Riemannian path space with intrinsic distance induced by the Malliavin gradient.

operator, and \([B, 27]\) on the path space of diffusions with the uniform distance. The main purpose of this paper is to investigate the Talagrand inequality on the path space of reflecting diffusion process, for which both the curvature and the second fundamental form of the boundary will take important roles.

Let \(M\) be a connected complete Riemannian manifold possibly with a boundary \(\partial M\). Let \(L = \Delta + Z\) for a \(C^1\) vector field \(Z\) on \(M\). Let \(X_t\) be the (reflecting if \(\partial M \neq \emptyset\)) diffusion process generated by \(L\) with initial distribution \(\mu \in \mathcal{P}(M)\), where \(\mathcal{P}(M)\) is the set of all probability measures on \(M\). Assume that \(X_t\) is non-explosive, which is the case if \(\partial M\) is convex and the curvature condition

\[
\text{Ric} - \nabla Z \geq -K
\]

holds for some constant \(K \in \mathbb{R}\). In this case, for any \(T > 0\), the distribution \(\Pi_T^\mu\) of \(X_{[0,T]} := \{X_t : t \in [0,T]\}\) is a probability measure on the (free) path space

\[
M^T := C([0,T]; M).
\]

When \(\mu = \delta_o\), the Dirac measure at point \(o \in M\), we simply denote \(\Pi_T^\delta_o = \Pi_T^o\).

For any nonnegative measurable function \(F\) on \(M_T\) such that \(\Pi_T^\mu(\{F\}) = 1\), one has

\[
\mu_T^\mu(dx) := \Pi_T^\mu(F) \mu(dx) \in \mathcal{P}(M).
\]

Let \(\rho\) be the Riemannian distance on \(M\); i.e. for \(x, y \in M\), \(\rho(x, y)\) is the length of the shortest curve on \(M\) linking \(x\) and \(y\). Then \(M^T\) is a Polish space under the uniform distance

\[
\rho_\infty(\gamma, \eta) = \sup_{t \in [0,T]} \rho(\gamma_t, \eta_t), \quad \gamma, \eta \in M^T.
\]

Let \(W_{2, \rho_\infty}\) be the \(L^2\)-Wasserstein distance (or \(L^2\)-transportation cost) induced by \(\rho_\infty\). In general, for any \(p \geq 1\) and for two probability measures \(\Pi_1, \Pi_2\) on \(M^T\),

\[
W_{p, \rho_\infty}(\Pi_1, \Pi_2) := \inf_{\pi \in \mathcal{C}(\Pi_1, \Pi_2)} \left\{ \int_{M_T \times M_T} \rho_\infty(\gamma, \eta)^p \pi(d\gamma, d\eta) \right\}^{1/p}
\]

is the \(L^p\)-Wasserstein distance (or \(L^p\)-transportation cost) of \(\Pi_1\) and \(\Pi_2\) induced by the uniform norm, where \(\mathcal{C}(\Pi_1, \Pi_2)\) is the set of all couplings for \(\Pi_1\) and \(\Pi_2\).

Before moving on, let us recall the Talagrand transportation-cost inequality established in \([B]\) on the path space over Riemannian manifolds without boundary. Let \(\partial M = \emptyset\) and \(\rho_o = \rho(o, \cdot)\). If

\[
|Z| \leq \psi \circ \rho_o
\]

holds for some constant \(K \in \mathbb{R}\). In this case, for any \(T > 0\), the distribution \(\Pi_T^\mu\) of \(X_{[0,T]} := \{X_t : t \in [0,T]\}\) is a probability measure on the (free) path space

\[
M^T := C([0,T]; M).
\]

When \(\mu = \delta_o\), the Dirac measure at point \(o \in M\), we simply denote \(\Pi_T^\delta_o = \Pi_T^o\).

For any nonnegative measurable function \(F\) on \(M_T\) such that \(\Pi_T^\mu(\{F\}) = 1\), one has

\[
\mu_T^\mu(dx) := \Pi_T^\mu(F) \mu(dx) \in \mathcal{P}(M).
\]

Let \(\rho\) be the Riemannian distance on \(M\); i.e. for \(x, y \in M\), \(\rho(x, y)\) is the length of the shortest curve on \(M\) linking \(x\) and \(y\). Then \(M^T\) is a Polish space under the uniform distance

\[
\rho_\infty(\gamma, \eta) = \sup_{t \in [0,T]} \rho(\gamma_t, \eta_t), \quad \gamma, \eta \in M^T.
\]

Let \(W_{2, \rho_\infty}\) be the \(L^2\)-Wasserstein distance (or \(L^2\)-transportation cost) induced by \(\rho_\infty\). In general, for any \(p \geq 1\) and for two probability measures \(\Pi_1, \Pi_2\) on \(M^T\),

\[
W_{p, \rho_\infty}(\Pi_1, \Pi_2) := \inf_{\pi \in \mathcal{C}(\Pi_1, \Pi_2)} \left\{ \int_{M_T \times M_T} \rho_\infty(\gamma, \eta)^p \pi(d\gamma, d\eta) \right\}^{1/p}
\]

is the \(L^p\)-Wasserstein distance (or \(L^p\)-transportation cost) of \(\Pi_1\) and \(\Pi_2\) induced by the uniform norm, where \(\mathcal{C}(\Pi_1, \Pi_2)\) is the set of all couplings for \(\Pi_1\) and \(\Pi_2\).

Before moving on, let us recall the Talagrand transportation-cost inequality established in \([B]\) on the path space over Riemannian manifolds without boundary. Let \(\partial M = \emptyset\) and \(\rho_o = \rho(o, \cdot)\). If

\[
|Z| \leq \psi \circ \rho_o
\]

holds for some constant \(K \in \mathbb{R}\). In this case, for any \(T > 0\), the distribution \(\Pi_T^\mu\) of \(X_{[0,T]} := \{X_t : t \in [0,T]\}\) is a probability measure on the (free) path space

\[
M^T := C([0,T]; M).
\]

When \(\mu = \delta_o\), the Dirac measure at point \(o \in M\), we simply denote \(\Pi_T^\delta_o = \Pi_T^o\).

For any nonnegative measurable function \(F\) on \(M_T\) such that \(\Pi_T^\mu(\{F\}) = 1\), one has

\[
\mu_T^\mu(dx) := \Pi_T^\mu(F) \mu(dx) \in \mathcal{P}(M).
\]

Let \(\rho\) be the Riemannian distance on \(M\); i.e. for \(x, y \in M\), \(\rho(x, y)\) is the length of the shortest curve on \(M\) linking \(x\) and \(y\). Then \(M^T\) is a Polish space under the uniform distance

\[
\rho_\infty(\gamma, \eta) = \sup_{t \in [0,T]} \rho(\gamma_t, \eta_t), \quad \gamma, \eta \in M^T.
\]

Let \(W_{2, \rho_\infty}\) be the \(L^2\)-Wasserstein distance (or \(L^2\)-transportation cost) induced by \(\rho_\infty\). In general, for any \(p \geq 1\) and for two probability measures \(\Pi_1, \Pi_2\) on \(M^T\),

\[
W_{p, \rho_\infty}(\Pi_1, \Pi_2) := \inf_{\pi \in \mathcal{C}(\Pi_1, \Pi_2)} \left\{ \int_{M_T \times M_T} \rho_\infty(\gamma, \eta)^p \pi(d\gamma, d\eta) \right\}^{1/p}
\]

is the \(L^p\)-Wasserstein distance (or \(L^p\)-transportation cost) of \(\Pi_1\) and \(\Pi_2\) induced by the uniform norm, where \(\mathcal{C}(\Pi_1, \Pi_2)\) is the set of all couplings for \(\Pi_1\) and \(\Pi_2\).

Before moving on, let us recall the Talagrand transportation-cost inequality established in \([B]\) on the path space over Riemannian manifolds without boundary. Let \(\partial M = \emptyset\) and \(\rho_o = \rho(o, \cdot)\). If

\[
|Z| \leq \psi \circ \rho_o
\]
holds for some positive function $\psi$ such that $\int_0^\infty \frac{1}{\psi(s)} \, ds = \infty$, then (see [6, Theorem 1.1])

$$W_{2,\rho_\infty}(F\Pi^T, \Pi^T_\infty) \leq \frac{2}{K}(e^{2KT} - 1)\Pi^T_\infty(F\log F), \quad F \geq 0, \Pi^T_\infty(F) = 1.$$  \hspace{1cm} (1.4)

According to [12, 4, 18], the log-Sobolev inequality for a smooth elliptic diffusion implies the Talagrand transportation-cost inequality with the intrinsic distance. So, (1.4) was proved in [6] by using a known damped log-Sobolev inequality on the path space and finite-dimensional approximations. To ensure the smoothness of the approximating diffusions, one needs the boundedness of curvature. To get rid of this condition, a sequence of new metric approximating the original one were constructed in [6], which satisfy (1.1) and have bounded curvatures. In this way (1.4) was established without using curvature upper bounds. But to realize this approximation argument, the technical condition (1.3) with $\int_0^\infty \frac{1}{\psi(s)} \, ds = \infty$ was adopted.

In this paper we adopt a different argument developed in [27] for diffusions on $\mathbb{R}^d$ by using the martingale representation theorem and Girsanov transformations, so that this technical condition was avoided. Furthermore, we present a number of cost inequalities which are equivalent to the convexity of $\partial M$ (if exists) and the curvature condition (1.1).

When $\partial M \neq \emptyset$, let $N$ be the inward unit normal vector field of $\partial M$. Then the second fundamental form of $\partial M$ is defined by

$$\llcorner(U, V) = -\langle \nabla U N, V \rangle, \quad U, V \in T\partial M,$$

where $T\partial M$ is the tangent space of $\partial M$. If $\llcorner \geq 0$, i.e. $\llcorner(U, U) \geq 0$ for all $U \in T\partial M$, we call $M$ (or $\partial M$) convex.

**Theorem 1.1.** Let $P_T(o, \cdot)$ be the distribution of $X_T$ with $X_0 = o$, and let $P_T$ be the corresponding semigroup. The following statements are equivalent to each other:

1. $\partial M$ is either convex or empty, and (1.1) holds.
2. For any $T > 0$, $\mu \in \mathcal{P}(M)$ and nonnegative $F$ with $\Pi^T_\mu(F) = 1$,

$$W_{2,\rho_\infty}(F\Pi^T_\mu, \Pi^T_\mu, F) \leq \frac{2}{K}(e^{2KT} - 1)\Pi^T_\mu(F\log F)$$

holds, where $\Pi^T_\mu \in \mathcal{P}(M)$ is fixed by (1.2).
3. (1.4) holds for any $o \in M$ and $T > 0$.
4. For any $o \in M$ and $T > 0$,

$$W_{2,\rho}(P_T(o, \cdot), fP_T(o, \cdot)) \leq \frac{2}{K}(e^{2KT} - 1)P_T(f\log f)(o),$$

$\quad f \geq 0, P_T f(o) = 1$. 

**Documenta Mathematica** 18 (2013) 297–322
For any $T > 0$, $\mu, \nu \in \mathcal{P}(M)$, and $p \geq 1$,

$$W_{p,\rho}(\Pi_T^\mu, \Pi_T^\nu) \leq e^{KT}W_{p,\rho}(\mu, \nu),$$

where $W_{p,\rho}$ is the $L^p$-Wasserstein distance for probability measures on $M$ induced by $\rho$.

For any $x, y \in M$ and $T > 0$,

$$W_{2,\rho}(P_T(x, \cdot), P_T(y, \cdot)) \leq e^{KT}\rho(x, y).$$

For any $T > 0$, $\mu \in \mathcal{P}(M)$, and $F \geq 0$ with $\Pi_T^\mu(F) = 1$,

$$W_{2,\rho\infty}(F\Pi_T^\mu, \Pi_T^\mu) \leq \left\{\frac{2}{K}(e^{2KT} - 1)\Pi_T^\mu(F \log F)\right\}^{1/2} + e^{KT}W_{2,\rho}(\mu^T, \mu).$$

(8) For any $\mu \in \mathcal{P}(M)$ and $C \geq 0$ such that $W_{2,\rho}(f\mu, \mu)^2 \leq C\mu(f \log f)$, $f \geq 0$, $\mu(f) = 1$,

there holds

$$W_{2,\rho\infty}(F\Pi_T^\mu, \Pi_T^\mu)^2 \leq \left(\frac{2}{K}(e^{2KT} - 1) + e^{KT}\sqrt{C}\right)^2 \Pi_T^\mu(F \log F),$$

$$F \geq 0, \Pi_T^\mu(F) = 1.$$
3 we prove Theorem 1.1 by using results in Section 2, the martingale representation and Girsanov transformation for (reflecting) diffusions on (convex) manifolds.

To establish transportation-cost inequalities on the path space for non-convex manifolds, we shall adopt a conformal change of metric \( \langle \cdot, \cdot \rangle' = f^{-2} \langle \cdot, \cdot \rangle \) such that \( \partial M \) is convex under the new metric (see [21, Lemma 2.1]). Let \( \Delta' \) be the Laplacian induced by the new metric, we have (see [21, Lemma 2.2])

\[
L = f^{-2} \left\{ \Delta' + f^2 Z + \frac{d - 2}{2} \nabla f^2 \right\}. \tag{1.5}
\]

According to this fact, we will modify our arguments in Section 4 to study the reflecting diffusion process generated by \( L := \psi^2 (\Delta + Z) \) for a smooth function \( \psi \) on a convex manifold, then extend Theorem 1.1 in Section 5 to the non-convex setting.

2 Formulae for the second fundamental form and applications

When \( M \) is compact, the following formula on \( \partial M \) has been found in [22]:

\[
\lim_{t \to 0} \frac{\| \nabla f \|^2}{\sqrt{t}} \log \left( \frac{\| \nabla P_t f \|}{(P_t \| \nabla f \|^p)^{1/p}} \right) = -\frac{2}{\sqrt{\pi}} I(\nabla f, \nabla f), \quad p \geq 1, \tag{2.1}
\]

where \( f \) is a smooth function satisfying the Neumann boundary condition. When \( M \) is non-compact, some technical problems appear in the original proof when e.g. a dominated convergence is used. To fix these problems, we shall stop the process in a compact domain, so that we shall first study the behavior of hitting times.

Recall that the reflecting \( L \)-diffusion process can be constructed by solving the SDE

\[
dX_t = \sqrt{2} \Phi_t \circ dB_t + Z(X_t)dt + N(X_t)dl_t, \tag{2.2}
\]

where \( \Phi_t \) is the horizontal lift of \( X_t \) onto the frame bundle \( O(M) \), \( B_t \) is the \( d \)-dimensional Brownian motion.

By the It\( ô \) formula, for any \( f \in C^2(M) \) we have

\[
df(X_t) = \sqrt{2} (\nabla f(X_t), \Phi_t \circ dB_t) + Lf(X_t)dt + Nf(X_t)dl_t, \tag{2.3}
\]

where \( Nf = \langle N, \nabla f \rangle \). For any \( R > 0 \), let

\[
\tau_R = \inf\{ t \geq 0 : \rho(X_0, X_t) \geq R \}.
\]

Proposition 2.1. Let \( R > 0 \) and \( X_0 = o \in M \) be fixed. Then there exist two constants \( c_1, c_2 > 0 \) such that

\[
P(\tau_R \leq t) \leq c_1 e^{-c_2/t}, \quad t > 0.
\]
Proof. This result is well known on manifolds without boundary (cf. [2, Lemma 2.3]), and the proof works also when \( \partial M \) is convex. As in the present case the boundary is not necessarily convex, we shall follow [21] to make the boundary convex under a conformal change of metric. Since
\[
B_R := \{ x \in M : \rho(o, x) \leq R \}
\]
is compact, there exists a constant \( \sigma > 0 \) such that \( I \geq -\sigma \) holds on \( \partial M \cap B_R \).
Let \( f \geq 1 \) be smooth such that
\[
N \log f \geq \sigma \quad \text{on} \quad \partial M \cap B_R.
\]
Such a function can be constructed by using the distance function \( \rho_o \) to the boundary \( \partial M \). Since \( \rho_o \) is smooth in a neighborhood of the boundary, there exists a constant \( r_0 > 0 \) such that \( \rho_o \) is smooth on \( \{ x \in B_{2R} : \rho_o(x) \leq r_0 \} \).
Let \( h \in C^\infty([0, \infty)) \) such that \( h' \geq 0, h(0) = 1, h'(r) = 0 \) for \( r \geq r_0 \). Then \( h \circ \rho_o \) is smooth on \( B_{2R} \) and \( N \log h \circ \rho_o |_{\partial M \cap B_{2R}} = \sigma \). Thus, it suffices to take smooth \( f \geq 1 \) such that \( f = h \circ \rho_o \) on \( B_R \).
By [21] Lemma 2.1 and (2.4), \( \partial M \) is convex in \( B_R \) under the new metric
\[
\langle \cdot, \cdot \rangle' = f^{-2} \langle \cdot, \cdot \rangle,
\]
where \( \langle \cdot, \cdot \rangle \) is the original metric. Let \( \Delta' \) be the Laplacian induced by the new metric. We have (see [21] Lemma 2.2)
\[
L = f^{-2} (\Delta' + Z')
\]
for some \( C^1 \)-vector field \( Z' \). Let \( \tilde{\rho}_o \) be the Riemannian distance to \( o \) induced by the new metric. By the Laplacian comparison theorem,
\[
L \tilde{\rho}_o^2 \leq c \quad \text{on} \quad B_R
\]
holds for some constant \( c > 0 \) outside the cut-locus induced by \( \langle \cdot, \cdot \rangle' \). Since \( \partial M \) is convex on \( B_R \) and \( N \) is still the inward normal vector under the new metric, we have
\[
N \tilde{\rho}_o \leq 0 \quad \text{on} \quad \partial M \cap B_R.
\]
Therefore, by using Kendall’s Itô formula for the distance (cf. [3] for \( f = 1 \), [21] implies
\[
d \tilde{\rho}_o^2(X_t) \leq 2\sqrt{2} f^{-2}(X_t) \tilde{\rho}_o(X_t) dt + c dt, \quad t \leq \tau R,
\]
or equivalently,
\[
t \mapsto 2\sqrt{2} \int_0^{t \wedge \tau R} f^{-2}(X_s) \tilde{\rho}_o(X_s) ds + c(t \wedge \tau R) - \tilde{\rho}_o^2(X_{t \wedge \tau R})
\]
is an increasing process, where \( b_t \) is some one-dimensional Brownian motion. Since \( f^{-2} \leq 1 \), this implies that for any \( \delta > 0 \), the process

\[ \text{Documenta Mathematica 18 (2013) 297–322} \]
\[ Z_s := \exp \left[ \frac{\delta_s}{t} \rho_o(X_s) - \frac{\delta c s}{t} - \frac{4 \delta^2 t}{t^2} \int_{0}^{s} \rho_o(X_u) du \right], \quad s \leq \tau_R \]

is a super martingale. Therefore, letting \( C > 1 \) be a constant such that \( f \leq C \) on \( B_R \) and thus, \( \rho_o \geq \tilde{\rho}_o \geq C^{-1} \rho_o \) holds on \( B_R \), we obtain

\[
P(\tau_R \leq t) = P \left( \max_{s \in [0,t]} \rho_o(X_{s \wedge \tau_R}) \geq R \right) \leq P \left( \frac{R}{C} \geq \max_{s \in [0,t]} \tilde{\rho}_o(X_{s \wedge \tau_R}) \geq \frac{R}{C} \right)
\]

\[
\leq P \left( \max_{s \in [0,t]} Z_{s \wedge \tau_R} \geq \exp \left[ \frac{\delta R^2}{tC^2} - \delta c - \frac{4 \delta^2 R^2}{t} \right] \right)
\]

\[
\leq \exp \left[ c\delta - \frac{R^2}{tC^2} (\delta - 4C^2 \delta^2) \right], \quad \delta > 0.
\]

The proof is then completed by taking e.g. \( \delta = 1/(8C^2) \).

**Proposition 2.2.** Let \( X_0 = o \in \partial M \). Then for any \( R > 0 \),

\[
\limsup_{t \to 0} \frac{1}{t} \left| \mathbb{E} \left[ l_{t \wedge \tau_R} - 2 \sqrt{t/\pi} \right] \right| \leq \infty.
\]

**Proof.** Repeating the proof of [22, Lemma 2.2] by using \( t \wedge \tau_R \) in place of \( t \), we obtain

\[
\mathbb{E} l_{t \wedge \tau_R} \leq ct, \quad t \in [0,1] \tag{2.6}
\]

for some constant \( c > 0 \). Let \( r_0 > 0 \) be such that \( \rho_o \) is smooth on \( \{ \rho_o \leq r_0 \} \cap B_R \).

Let

\[
\tau = \inf \{ t \geq 0 : \rho_o(X_t) \geq r_0 \}.
\]

By the Itô formula we have

\[
d\rho_o(X_t) = \sqrt{2} dB_t + L \rho_o(X_t) dt + \frac{dt}{2}, \quad t \leq \tau \wedge \tau_R, \tag{2.7}
\]

where, as before, \( b_t \) is some one-dimensional Brownian motion. By the proof of [22, Theorem 2.1] using \( \tau \wedge \tau_R \) in place of \( \tau \), we have, instead of (2.4) in [22],

\[
\mathbb{E} (\rho_o(X_{t \wedge \tau \wedge \tau_R}) - \sqrt{2} |b_{t \wedge \tau \wedge \tau_R}|)^2 \leq c_1 t^2, \quad t \in [0,1] \tag{2.8}
\]

for some constant \( c_1 > 0 \), where \( \tilde{b}_t \) is some one-dimensional Brownian motion. Due to (2.7),

\[
\left| \mathbb{E} l_{t \wedge \tau \wedge \tau_R} - \mathbb{E} \rho_o(X_{t \wedge \tau \wedge \tau_R}) \right| \leq c_2 t
\]

holds for some constant \( c_2 > 0 \). Combining this with (2.8) we arrive at

\[
\left| \mathbb{E} l_{t \wedge \tau \wedge \tau_R} - \sqrt{2} \mathbb{E} |\tilde{b}_{t \wedge \tau \wedge \tau_R}| \right| \leq c_3 t, \quad t \in [0,1]
\]
for some constant $c_3 > 0$. Since $\mathbb{E}|\hat{b}_t| = \sqrt{2t/\pi}$ and $\mathbb{E}|\hat{b}_t|^2 = t$, this and (2.3) imply

$$\left|\mathbb{E}I_{t\wedge\tau_R} - \frac{2\sqrt{t}}{\sqrt{\pi}}\right| = \left|\mathbb{E}I_{t\wedge\tau_R} - \sqrt{2}\mathbb{E}|\hat{b}_t|\right|$$

$$\leq c_3 t + \mathbb{E}I_{1_{t\geq\tau\wedge\tau_R}}(t_{\wedge\tau_R} + \sqrt{2}|\hat{b}_t|)$$

$$\leq c_3 t + c_4 \sqrt{\log(t)}(t \geq \tau \wedge \tau_R), \quad t \in [0, 1].$$

Moreover, noting that

$$\mathbb{P}(\tau \wedge \tau_R \leq t, \tau_R > \tau) \leq \mathbb{P}\left(\max_{s \in [0, t]} \rho_0(X_{s\wedge\tau \wedge \tau_R}) \geq r_0\right),$$

by using $\tau \wedge \tau_R$ to replace $\tau$ in the proof of [22, Proposition A.2], we conclude that

$$\mathbb{P}(\tau \wedge \tau_R \leq t, \tau_R > \tau) \leq c_5 \exp[-r_0^2/(16t)], \quad t > 0$$

holds for some constant $c_5 > 0$. Combining this with Proposition 2.1, we obtain

$$\mathbb{P}(t \geq \tau \wedge \tau_R) \leq c_6 e^{-c_7/t}, \quad t > 0$$

for some constants $c_6, c_7 > 0$. Therefore, the proof is completed by (2.9).

**Theorem 2.3.** Let $f \in C^\infty(M)$ with $Nf|_{\partial M} = 0$. 

1. For any $p \geq 1$ and $R > 0$,

$$\lim_{t \to 0} \frac{\|\nabla f\|^2}{\sqrt{t}} \log \left(\frac{\mathbb{E}(|\nabla f|^p(X_{t\wedge\tau_R}))^{1/p}}{|\nabla f|}\right) = \frac{2}{\sqrt{\pi}} \|\nabla f, \nabla f\| (2.10)$$

holds at points on $\partial M$ such that $|\nabla f| > 0$.

2. Assume that for any $g \in C^\infty_0(M)$ the function $|\nabla Pg|$ is bounded on $[0, 1] \times M$. If moreover $f$ has a compact support, then (2.7) holds points on $\partial M$ such that $|\nabla f| > 0$.

**Proof.** (2.10) follows immediately from the proof of [22, Theorem 1.2] by using Proposition 2.2 in place of [22, Theorem 2.1], and using $t \wedge \tau_R$ in place of $t$. Next, let $f \in C^\infty_0(M)$. By the assumption of (2) and that $L^f \in C^\infty_0(M)$, $|\nabla PLf|$ is bounded on $[0, 1] \times M$. So, the proof of [22, (3.1)] implies that

$$\lim_{t \to 0} \frac{\|\nabla f\|^2}{\sqrt{t}} \log \left(\frac{\mathbb{E}(|\nabla f|^p(X_{t\wedge\tau_R}))^{1/p}}{|\nabla f|}\right) = -\lim_{t \to 0} \frac{\|\nabla f\|^2}{\sqrt{t}} \log \left(\frac{\mathbb{E}(P_t|\nabla f|^p)^{1/p}}{|\nabla f|}\right). (2.11)$$

Since by Proposition 2.1 there exist two constant $c_1, c_2 > 0$ such that

$$|P_t|\nabla f|^p - \mathbb{E}|\nabla f|^p(X_{t\wedge\tau_R})| \leq ||\nabla f||_\infty \mathbb{P}(t > \tau_R) \leq c_1 e^{-c_2/t}, \quad t > 0,$$

we conclude that (2.11) follows from (2.11) and (2.10).
As an application of (2.10), the following result provides equivalent semigroup log-Sobolev/Poincaré inequalities for Theorem 1.1(1).

**Theorem 2.4.** Each of the following statements is equivalent to Theorem 1.1(1):

(9) For any $T > 0$ and $f \in C_b(M)$,

$$P_T f^2 \log f^2 \leq (P_T f^2) \log P_T f^2 + \frac{e^{2KT} - 1}{2K} \|\nabla f\|^2.$$  

(10) For any $T > 0$ and $f \in C_b(M)$,

$$P_T f^2 \leq (P_T f)^2 + \frac{e^{2KT} - 1}{K} \|\nabla f\|^2.$$

**Proof.** According to e.g. [16, Lemma 3.1], which holds also for the non-symmetric case, Theorem 1.1(1) implies the semigroup log-Sobolev inequality (9). It is well known that the log-Sobolev inequality implies the Poincaré inequality. So, (10) follows from (9). Hence, it remains to show that (10) implies Theorem 1.1(1). Below we shall prove the convexity of $\partial M$ and the curvature condition (1.1) respectively.

(a) Let $\partial M \neq \emptyset$. For any $o \in \partial M$ and non-trivial $U \in T_o \partial M$, we aim to show that $I(U, U) \geq 0$. Let $f \in C_0^\infty(M)$ such that $Nf|_{\partial M} = 0$ and $\nabla f(o) = U$. Let $X_0 = o$ and $\tau_1 = \inf\{t \geq 0 : \rho(o, X_t) \geq 1\}$.

Since $f$ and $f^2$ satisfies the Neumann boundary condition, we have

$$\mathbb{E} f(X_{t \wedge \tau_1}) = f(o) + \mathbb{E} \int_0^{t \wedge \tau_1} Lf(X_s)ds,$$

$$\mathbb{E} f^2(X_{t \wedge \tau_1}) = f^2(o) + 2\mathbb{E} \int_0^{t \wedge \tau_1} (fLf)(X_s)ds + 2\mathbb{E} \int_0^{t \wedge \tau_1} |\nabla f|^2(X_s)ds.$$

So,

$$\mathbb{E} f^2(X_{t \wedge \tau_1}) - \{\mathbb{E} f(X_{t \wedge \tau_1})\}^2 = 2\mathbb{E} \int_0^{t \wedge \tau_1} \{f(X_s) - f(X_0)\} Lf(X_s)ds$$

$$- \left( \mathbb{E} \int_0^{t \wedge \tau_1} Lf(X_s)ds \right)^2 + 2\mathbb{E} \int_0^{t \wedge \tau_1} |\nabla f|^2(X_s)ds. \quad (2.12)$$

Since $Lf$ is bounded on $B_1 := \{x : \rho(o, x) \leq 1\}$, we have

$$\left( \mathbb{E} \int_0^{t \wedge \tau_1} Lf(X_s)ds \right)^2 \leq ct^2 \quad (2.13)$$

**Documenta Mathematica 18 (2013) 297–322**
for some $c > 0$. Moreover, due to Proposition 2.1,

$$P(\tau_1 \leq t) \leq c_1 e^{-c_2 / t}, \quad t > 0 \quad (2.14)$$

holds for some constants $c_1, c_2 > 0$. Thus,

$$|P_t f^2(o) - (P_t f)^2(o) - (E f^2(X_{t \wedge \tau_1}) - \{E f(X_{t \wedge \tau_1})\}^2)| = o(t^2),$$

$$\mathbb{E} \int_0^{t \wedge \tau_1} |\nabla f|^2(X_s) ds = t|\nabla f(o)|^2 + \int_0^t \mathbb{E} \{ |\nabla f|^2(X_{s \wedge \tau_1}) - |\nabla f(o)|^2 \} ds + o(t^2), \quad (2.15)$$

where and in what follows, $o(s)$ stands for a function of $s > 0$ such that

$$\lim_{s \to 0} o(s) / s = 0.$$

Similarly, applying the Itô formula to $\{ f(X_s) - f(o) \} Lf(X_s)$, we obtain (note that $Nf|_{\partial M} = 0$)

$$\mathbb{E} \int_0^{t \wedge \tau_1} \{ f(X_s) - f(o) \} Lf(X_s) ds$$

$$= o(t^2) + \int_0^t \mathbb{E} \{ (f(X_{s \wedge \tau_1}) - f(o)) Lf(X_{s \wedge \tau_1}) \} ds$$

$$= o(t^2) + \mathbb{E} \int_0^t ds \int_0^{s \wedge \tau_1} L((f - f(o)) Lf)(X_r) dr$$

$$+ \mathbb{E} \int_0^t ds \int_0^{s \wedge \tau_1} \{ (f - f(o)) NLf \}(X_r) dl_r. \quad (2.16)$$

Noting that

$$f(X_r) - f(o) = \sqrt{2} \int_0^r \langle \nabla f(X_u), \Phi_u \circ dB_u \rangle + \int_0^r Lf(X_u) du, \quad u \leq \tau_1,$$

and that

$$\mathbb{E} \sup_{r \in [0, t]} \left( \int_0^r \langle \nabla f(X_u), \Phi_u \circ dB_u \rangle \right)^2 \leq c_2 t, \quad t \in [0, 1]$$

holds for some constant $c_2 > 0$, we obtain from (2.16) and (2.6) that

$$\mathbb{E} \int_0^{t \wedge \tau_1} \{ f(X_s) - f(o) \} Lf(X_s) ds \leq c_3 t^2, \quad t \in [0, 1] \quad (2.17)$$

holds for some constant $c_3 > 0$. Finally, by Theorem 2.3(1), we have

$$\mathbb{E} |\nabla f|^2(X_{t \wedge \tau_1}) = |\nabla f|^2(o) + \frac{4 \sqrt{t}}{\sqrt{\pi}} \lVert \nabla f \rVert + o(t^{1/2}) \quad (2.18)$$
Combining this with (2.12), (2.13), (2.15) and (2.17), and noting that $U = \nabla f(o)$, we conclude that
\[ P tf^2(o) - (P tf)^2(o) = 2 t |\nabla f(o)|^2 + \frac{16 t^{3/2}}{3\sqrt{\pi}} \mathbb{I}(U, U) + o(t^{3/2}). \]  
(2.19)

Finally, (2.18) and (2.14) imply that
\[ \frac{e^{2Kt}}{K} P tf^2(o) = 2 t |\nabla f(o)|^2 + \frac{8t^{3/2}}{\sqrt{\pi}} \mathbb{I}(U, U) + o(t^{3/2}). \]

Since $\frac{16}{3} < 8$, combining this with (10) and (2.19) we conclude that $\mathbb{I}(U, U) \geq 0$.

(b) Let $X_o = o \in M \setminus \partial M$, we aim to show that $\text{Ric} - \nabla Z \geq - K$ holds on $T_o M$.

Let $R > 0$ such that $B_R \cap \partial M = \emptyset$. Since $l_t$ increases only when $X_t \in \partial M$, $l_t = 0$ for $t \leq \tau_R$. Hence, due to Proposition 2.1 for any $f \in C^\infty_o(M)$,

\[ P tf^2(o) - (P tf)^2(o) = o(t^2) + \mathbb{E} f^2(X_{t \wedge \tau_R}) - \left( \mathbb{E} f(X_{t \wedge \tau_R}) \right)^2. \]

By the continuity of $s \mapsto \mathbb{L} f(X_{s \wedge \tau_R})$, we have
\[ \left( \int_0^t \mathbb{E} f(X_{s \wedge \tau_R}) ds \right)^2 = (L f)^2(o) t^2 + o(t^2). \]

Similarly, it is easy to see that
\[ \mathbb{E} f^2(X_{s \wedge \tau_R}) - 2 f(o) \mathbb{E} L f(X_{s \wedge \tau_R}) \]
\[ = L f^2(o) - 2 f(o) L f(o) + s \{ L f^2 - 2 f LL f \}(0) + o(s) \]
\[ = 2 |\nabla f|^2(o) + 2 s \{ |\nabla f|^2 + (L f)^2(o) + 2 \langle \nabla f, \nabla L f \rangle(o) \} + o(s). \]

Combining this with (2.20) and (2.21) we obtain
\[ P tf^2(o) - (P tf)^2(o) = 2 t |\nabla f(o)|^2 + t^2 \{ L |\nabla f|^2 + 2 \langle \nabla f, \nabla L f \rangle \}(o) + o(t^2). \]

(2.22)

Finally, by Proposition 2.1 and noting that $l_s = 0$ for $s \leq \tau_R$, we have
\[ P t |\nabla f|^2(o) = o(t^2) + \mathbb{E} |\nabla f|^2(X_{t \wedge \tau_R}) = |\nabla f|^2(o) + t L |\nabla f|^2(o) + o(t). \]

Combining this with (10) and (2.22), we conclude that
\[ \frac{1}{2} L |\nabla f|^2(o) - \langle \nabla f, \nabla L f \rangle(o) \geq - K |\nabla f|(o), \quad f \in C^\infty_o(M). \]

This completes the proof by the Bochner-Weitzenböck formula.
3 Proof of Theorem 1.1

By taking \( \mu = \delta_\alpha \), we have \( \mu_T^T = \Pi_\alpha^T(F) \delta_\alpha = \delta_\alpha \). So, (3) follows from each of (2), (7) and (8). Next, (4) follows from (3) by taking \( F(X_{[0,T]}) = f(X_T) \), and (5) implies (6) by taking \( p = 2 \) and \( \mu = \delta_x, \nu = \delta_y \). Moreover, it is clear that (8) follows from (7) while (7) is implied by (2) and (5). So, it suffices to prove that (1) \( \Rightarrow \) (3) \( \Rightarrow \) (2), (4) \( \Rightarrow \) (1) \( \Rightarrow \) (6) \( \Rightarrow \) (5) and (6) \( \Rightarrow \) (1), where "\( \Rightarrow \)" stands for "implies".

(a) (1) \( \Rightarrow \) (3). We shall only consider the case where \( \partial M \) is non-empty and convex. For the case without boundary, the following argument works well by taking \( \lambda_t = 0 \) and \( N = 0 \). The idea of the proof comes from [27], where elliptic diffusions on \( \mathbb{R}^d \) were concerned. Let \( B_t \) be the \( d \)-dimensional Brownian motion on the naturally filtered probability space \( (\Omega, \mathcal{F}_t, P) \). Let \( \{ X_t : t \geq 0 \} \) solve (2.2) with \( X_0 = o \).

Next, let \( F \) be a positive bounded measurable function on \( M_T \) such that \( \inf F > 0 \) and \( \Pi_\mu^T(F) = 1 \). Then

\[
 m_t := E_P(F(X_{[0,T]}))|\mathcal{F}_t) \quad \text{and} \quad L_t := \int_0^t \frac{dm_s}{m_s}, \quad t \in [0,T]
\]

are square-integrable \( \mathcal{F}_t \)-martingales under \( P \), where \( E_P \) is the expectation taken for the probability measure \( P \). Obviously, we have

\[
 m_t = e^{L_t - \frac{1}{2} \langle L \rangle_t}, \quad t \in [0,T]. \tag{3.1}
\]

Since \( \mathcal{F}_t \) is the natural filtration of \( B_t \), by the martingale representation theorem (cf. [8, Theorem 6.6]), there exists a unique \( \mathcal{F}_t \)-predictable process \( \beta_t \) on \( \mathbb{R}^d \) such that

\[
 L_t = \int_0^t \langle \beta_s, dB_s \rangle, \quad t \in [0,T]. \tag{3.2}
\]

Let \( dQ = F(X_{[0,T]})d\mathbb{P} \). Since \( E_P F(X_{[0,T]}) = \Pi_\mu^T(F) = 1 \), \( Q \) is a probability measure on \( \Omega \). Due to (3.1) and (3.2) we have

\[
 F(X_{[0,T]}) = m_T = e^{\int_0^T \langle \beta_s, dB_s \rangle - \frac{1}{2} \int_0^T \| \beta_s \|^2 ds}.
\]

Moreover, by the Girsanov theorem,

\[
 \tilde{B}_t := B_t - \int_0^t \beta_s ds, \quad t \in [0,T] \tag{3.3}
\]

is a \( d \)-dimensional Brownian motion under the probability measure \( Q \).

Let \( Y_t \) solve the SDE

\[
 dY_t = \sqrt{2} P_{X_t,Y_t} \Phi_t \circ dB_t + Z(Y_t)dt + N(Y_t)d\tilde{l}_t, \quad Y_0 = o, \tag{3.4}
\]

where \( P_{X_t,Y_t} \) is the parallel displacement along the minimal geodesic from \( X_t \) to \( Y_t \) and \( \tilde{l}_t \) is the local time of \( Y_t \) on \( \partial M \). As explained in e.g. [10] Section
Finally, since (3.1) and (3.2) yield
\[ E \parallel \beta \parallel^2 = E\left(\parallel \beta_s \parallel^2 \right), \]
we conclude that under \( Q \) the distribution of \( X_{[0,T]} \) coincides with \( F\Pi_T^\rho \). Therefore,
\[ W_{2,\infty}(F\Pi_T^\rho, \Pi_T^\rho) \leq E_Q(\rho(0,T), Y_{[0,T]})^2 = E_Q \max_{t\in[0,T]} \rho(X_t, Y_t)^2. \]
By the convexity of \( \partial M \) we have
\[ \langle N(x), \nabla \rho(y, \cdot)(x) \rangle = \langle N(x), \nabla \rho(\cdot, y)(x) \rangle \leq 0, \quad x \in \partial M. \]
Combining this with the Itô formula for \( (X_t, Y_t) \) given by (3.1) and (3.2), we obtain from (3.4) that
\[ d \rho(X_t, Y_t) \leq K \rho(X_t, Y_t) dt + \sqrt{2} \langle \dot{\Phi}_t, \nabla \rho(\cdot, Y_t)(X_t) \rangle dt \]
\[ \leq \left( K \rho(X_t, Y_t) + \sqrt{2} \parallel \beta_t \parallel \right) dt, \]
see e.g. [15] Lemmas 2.1 and 2.2. Since we are using the coupling by parallel displacement instead of the mirror reflection, the martingale part here disappears (cf. Theorem 2 and (2.5) in [9]). Since \( X_0 = Y_0 \), this implies
\[ \rho(X_t, Y_t)^2 \leq e^{2Kt} \left( \sqrt{2} \int_0^t e^{-Ks} \parallel \beta_s \parallel ds \right)^2 \leq \frac{e^{2Kt} - 1}{K} \int_0^t \parallel \beta_s \parallel^2 ds, \quad t \in [0,T]. \]
Therefore,
\[ E_Q \max_{t\in[0,T]} \rho(X_t, Y_t)^2 \leq \frac{e^{2KT} - 1}{K} \int_0^T E_Q \parallel \beta_s \parallel^2 ds. \]
It is clear that
\[ E_Q \parallel \beta_s \parallel^2 = E\left(\parallel \beta_s \parallel^2 \right) = E\left(\parallel \beta_s \parallel^2 E\left(\parallel \beta_s \parallel^2 \right) \right) = E\left(\parallel \beta_s \parallel^2 \right), \quad s \in [0,T]. \]
\[ d(m)_t = m_t^2 d(L)_t = m_t^2 \| \beta_t \|^2 dt, \]

we have

\[
d m_t \log m_t = (1 + \log m_t) d m_t + \frac{d(m)_t}{2m_t}
= (1 + \log m_t) d m_t + \frac{m_t}{2} \| \beta_t \|^2 dt.
\]

As \( m_t \) is a \( \mathbb{P} \)-martingale, combining this with (3.8) we obtain

\[
\int_0^T \mathbb{E} \| \beta_s \|^2 ds = 2 \mathbb{E}_P F(X_{[0,T]}) \log F(X_{[0,T]}). \tag{3.9}
\]

Therefore, (1.4) follows from (3.6), (3.7) and (3.9).

(b) (3) \Rightarrow (2). By (3), for each \( x \in M \), there exists \( \pi_x \in C(F \Pi^T_x, \Pi^T_x) \) such that

\[
\int_M \rho \infty (\gamma, \eta)^2 \pi_x(d\gamma, d\eta) \leq \frac{2}{K} (e^{2KT} - 1) \Pi^T_x \left( \frac{F}{\Pi^T_x(F)} \log \frac{F}{\Pi^T_x(F)} \right). \tag{3.10}
\]

If \( x \mapsto \pi_x(G) \) is measurable for bounded continuous functions \( G \) on \( M^T \times M^T \), then

\[
\pi := \int_M \pi_x \mu^T_F(dx) \in C(\mu^T_F, \mu^T_F)
\]
is well defined and by (3.10)

\[
\int_{M^T \times M^T} \rho^2 \infty d\pi \leq \frac{2}{K} (e^{2KT} - 1) \int_M \Pi^T_x \left( F \log \frac{F}{\Pi^T_x(F)} \right) \mu(dx)
\leq \frac{2}{K} (e^{2KT} - 1) \Pi^T_{\mu} (F \log F).
\]

This implies the inequality in (2).

To confirm the measurability of \( x \mapsto \pi_x \), we first consider discrete \( \mu \), i.e. \( \mu = \sum_{n=1}^\infty \varepsilon_n \delta_{x_n} \) for some \( \{x_n\} \subset M \) and \( \varepsilon_n \geq 0 \) with \( \sum_{n=1}^\infty \varepsilon_n = 1 \). In this case

\[
\pi_x = \sum_{n=1}^\infty 1_{\{x=x_n\}} \pi_{x_n}, \quad \mu\text{-a.e.}
\]

which is measurable in \( x \) and \( \pi = \sum_{n=1}^\infty \mu^T_F (\{x_n\}) \pi_{x_n} \). Hence, the inequality in (2) holds. Then, for general \( \mu \), the desired inequality can be derived by
approximating \( \mu \) with discrete distributions in a standard way, see (b) in the proof of [\ref{6}, Theorem 4.1].

(c) (4) \( \Rightarrow \) (1). According to [\ref{12}, Section 7] (see also [\ref{4}, Section 4.1]), by first applying the transportation-cost inequality in (3) to \( 1 - \varepsilon + \varepsilon f \) in place of \( f \), then letting \( \varepsilon \to 0 \), we obtain the Poincaré inequality

\[
PT f^2 \leq \frac{e^{2KT}}{K} PT|\nabla f|^2 + (PT f)^2, \quad f \in C^1_b(M), T > 0.
\]  

(3.11)

Thus, the proof is finished by Theorem 2.4.

(d) (1) \( \Rightarrow \) (6). Let \( X_t \) solve (2.2) with \( X_0 = x \) and \( Y_t \) solve

\[
dY_t = \sqrt{2} \, d_{X_t,Y_t} \Phi_t \circ dB_t + Z(Y_t) \, dt - N(Y_t) \, d\tilde{t}, \quad Y_0 = y,
\]  

(3.12)

where \( \tilde{t} \) is the local time of \( Y_t \) on \( \partial M \). Since \( \partial M \) is convex and (1.1) holds, as explained in (a), we have

\[
d\rho(X_t,Y_t) \leq K \rho(X_t,Y_t) \, dt.
\]

Thus, \( \rho_\infty(X,Y) \leq e^{KT} \rho(x,y) \). This implies (6).

(e) (6) \( \Rightarrow \) (5). By (6), for any \( x,y \in M \), there exists \( \pi_{x,y} \in C(\Pi^T_x, \Pi^T_y) \) such that

\[
\int_{M^T \times M^T} \rho_\infty^p \, d\pi_{x,y} \leq e^{KT} \rho(x,y)^p.
\]

As explained in (b), we assume that \( \mu \) and \( \nu \) are discrete, so that for any \( \pi^0 \in (\mu, \nu) \), \( \pi_{x,y} \) has a \( \pi^0 \)-version measurable in \( (x,y) \). Thus,

\[
\pi := \int_{M \times M} \pi_{x,y} \pi^0(dx,dy) \in C(\Pi^T_\mu, \Pi^T_\nu)
\]

satisfies

\[
\int_{M^T \times M^T} \rho_\infty^p \, d\pi \leq e^{KT} \int_{M^T \times M^T} \rho(x,y)^p \, d\pi^0(d\pi_{x,y}).
\]

This implies the desired inequality in (5).

(f) (6) \( \Rightarrow \) (1). Let \( T > 0 \) be fixed. For any \( x,y \in M \), let \( \pi_{x,y} \in C(PT(x,\cdot), PT(y,\cdot)) \) be the optimal coupling for \( W_{2,\rho} \), i.e.

\[
W_{2,\rho}(PT(x,\cdot), PT(y,\cdot))^2 = \int_{M \times M} \rho^2 \, d\pi_{x,y}.
\]  

(3.13)
Then for any \( f \in C^2_b(M) \), (6) implies
\[
\frac{|Pt f(x) - Pt f(y)|}{\rho(x, y)} \leq \int_{M \times M} \frac{|f(z_1) - f(z_2)|}{\rho(z_1, z_2)^2} \cdot \pi_{x,y}(dz_1, dz_2) \rho(x, y)
\]
\[
\leq W_{2, \rho}(Pt(x, \cdot), Pt(y, \cdot)) \left\{ \int_{M \times M} \frac{(f(z_1) - f(z_2))^2}{\rho(z_1, z_2)^2} \pi_{x,y}(dz_1, dz_2) \right\}^{1/2}
\]
\[
\leq e^{KT} \left\{ \int_{M \times M} \frac{(f(z_1) - f(z_2))^2}{\rho(z_1, z_2)^2} \pi_{x,y}(dz_1, dz_2) \right\}^{1/2}.
\]
(3.14)

Noting that \( f \in C^2_b(M) \) implies
\[
|f(z_1) - f(z_2)|^2 \leq \rho(z_1, z_2)^2|\nabla f|^2(z_1) + c\rho(z_1, z_2)^3
\]
for some constant \( c > 0 \), by (6) and (3.13) we obtain
\[
\int_{M \times M} \frac{(f(z_1) - f(z_2))^2}{\rho(z_1, z_2)^2} \pi_{x,y}(dz_1, dz_2) \leq Pt|\nabla f|^2(x) + c e^{KT} \rho(x, y).
\]
Therefore, letting \( y \to x \) in (3.14) we arrive at
\[
|\nabla Pt f(x)| \leq e^{KT} (Pt|\nabla f|^2(x))^{1/2}.
\]
By a standard argument of Bakry and Emery, this implies the Poincaré inequality (3.11). Thus, (1) holds according to Theorem 2.4.

4 The case with a diffusion coefficient

Let \( \psi > 0 \) be a smooth function on \( M \), and let \( \Pi_{\mu, \psi}^T \) be the distribution of the (reflecting if \( \partial M \neq \emptyset \)) diffusion process generated by \( L_{\psi} := \psi^2(\Delta + Z) \) on time interval \([0, T]\) with initial distribution \( \mu \), and let \( \Pi_{x,\psi}^T = \Pi_{\delta_x, \psi}^T \) for \( x \in M \). Moreover, for \( F \geq 0 \) with \( \Pi_{\mu, \psi}^T(F) = 0 \), let
\[
\mu_{T,\psi}^T(dx) = \Pi_{x,\psi}^T(F) \mu(dx).
\]

Theorem 4.1. Assume that \( \partial M \) is either empty or convex and let (1.1) hold.
Let \( \psi \in C^\infty_b(M) \) be strictly positive. Let
\[
K_{\psi} = K^+ \|\psi\|_\infty^2 + 2\|Z\|_\infty \|\nabla \psi\|_\infty \|\psi\|_\infty + (d - 1) \|\nabla \psi\|_\infty^2.
\]
Then
\[
W_{2, \rho_{\psi}}(F\Pi_{\mu, \psi}^T, \Pi_{\mu_{T, \psi}^T, \psi}^T)^2 \leq 2C(T, \psi)\Pi_{\mu, \psi}^T(F \log F),
\]
\( \mu \in \mathcal{P}(M), \ F \geq 0, \ \Pi_{\mu, \psi}^T(F) = 1 \)
holds for

\[ C(T, \psi) := \inf_{R > 0} \left\{ (1 + R^{-1})\|\psi\|_\infty^2 \frac{e^{2K_T^{-1}} - 1}{K_\psi} \exp \left[ 2(1 + R)\|\nabla \psi\|_\infty^2 \frac{e^{2K_T^{-1}} - 1}{K_\psi} \right] \right\}. \]

**Proof.** As explained in (a) of the proof of Theorem 1.1, we shall only consider the case that \( \partial M \) is non-empty and convex. According to the proof of “\((3) \Rightarrow (2)\)”, it suffices to prove for \( \mu = \delta_o, o \in M \). In this case the desired inequality reduces to

\[ W_{2, \rho, \infty}^\ast (F \Pi_{o, \psi}^T, \Pi_{o, \psi}^T) \leq 2C(T, \psi)\Pi_{o, \psi}^T(F \log F), \quad F \geq 0, \Pi_{o, \psi}^T(F) = 1. \]  

(4.1)

Since the diffusion coefficient is non-constant, it is convenient to adopt the Itô differential \( d_I \) for the Girsanov transformation. So, the reflecting diffusion process generated by \( L_\psi := \psi^2(\nabla + Z) \) can be constructed by solving the Itô SDE

\[ d_I X_t = \sqrt{2} \psi(X_t) \Phi_t dB_t + \psi^2(X_t) Z(X_t) dt + N(X_t) dl_t, \]  

(4.2)

where \( X_0 = o \) and \( B_t \) is the \( d \)-dimensional Brownian motion with natural filtration \( \mathcal{F}_t \). Let \( \beta_t, Q \) and \( \tilde{B}_t \) be fixed in the proof of Theorem 1.1. Then

\[ d_I X_t = \sqrt{2} \psi(X_t) \Phi_t d\tilde{B}_t + \left\{ \psi^2(X_t) Z(X_t) + \sqrt{2} \psi(X_t) \Phi_t \beta_t \right\} dt + N(X_t) dl_t, \]  

(4.3)

Let \( Y_t \) solve

\[ d_I Y_t = \sqrt{2} \psi(Y_t) \Phi_t d\tilde{B}_t + \psi^2(Y_t) Z(Y_t) dt + N(Y_t) dl_t, \quad Y_0 = o, \]  

(4.4)

where \( \tilde{l}_t \) is the local time of \( Y_t \) on \( \partial M \). As in (a) of the proof of Theorem 1.1 under \( Q \), the distributions of \( Y_{[0, T]} \) and \( X_{[0, T]} \) are \( \Pi_{o, \psi}^T \) and \( F \Pi_{o, \psi}^T \) respectively. So,

\[ W_{2, \rho, \infty}^\ast (F \Pi_{o, \psi}^T, \Pi_{o, \psi}^T)^2 \leq \mathbb{E}_Q \max_{t \in [0, T]} \rho(X_t, Y_t)^2. \]  

(4.5)

Noting that due to the convexity of \( \partial M \)

\[ \langle N(x), \nabla \rho(y, \cdot)(x) \rangle = \langle N(x), \nabla \rho(\cdot, y)(x) \rangle \leq 0, \quad x \in \partial M, \]
by (4.3), (4.4) and the Itô formula, we obtain

\[
\begin{align*}
d\rho(X_t, Y_t) &\leq \sqrt{2} \left\{ \psi(X_t)(\nabla \rho(\cdot, Y_t)(X_t), \Phi_t d\dot{B}_t) \\
&\quad + \psi(Y_t)(\nabla \rho(X_t, \cdot)(Y_t), P_{X_t, Y_t} \Phi_t d\dot{B}_t) \right\} \\
&\quad + \left\{ \sum_{i=1}^{d-1} U_i^2 \rho(X_t, Y_t) + \langle \psi(X_t)^2 Z(X_t) + \sqrt{2} \psi(X_t) \Phi_t \beta_t, \nabla \rho(\cdot, Y_t)(X_t) \rangle \\
&\quad + \psi(Y_t)^2 (Z(Y_t), \nabla \rho(X_t, \cdot)(Y_t)) \right\} dt,
\end{align*}
\]

(4.6)

where \( \{U_i\}_{i=1}^{d-1} \) are vector fields on \( M \times M \) such that \( \nabla U_i(X_t, Y_t) = 0 \) and

\[ U_i(X_t, Y_t) = \psi(X_t)V_i + \psi(Y_t)P_{X_t, Y_t}V_i, \quad 1 \leq i \leq d - 1 \]

for \( \{V_i\}_{i=1}^d \) an OBN of \( T_X M \) with \( V_d = \nabla \rho(\cdot, Y_t)(X_t) \).

In order to calculate \( U_i^2 \rho(X_t, Y_t) \), we adopt the second variational formula for the distance. Let \( \rho_t = \rho(X_t, Y_t) \) and let \( \{J_i\}_{i=1}^{d-1} \) be Jacobi fields along the minimal geodesic \( \gamma : [0, \rho_t] \to M \) from \( X_t \) to \( Y_t \) such that \( J_i(0) = \psi(X_t)V_i \) and \( J_i(\rho_t) = \psi(Y_t)P_{X_t, Y_t}V_i, 1 \leq i \leq d - 1 \). Note that the existence of \( \gamma \) is ensured by the convexity of \( \partial M \). Then, by the second variational formula and noting that \( \nabla U_i(X_t, Y_t) = 0 \), we have

\[
I := \sum_{i=1}^{d-1} U_i^2 \rho(X_t, Y_t) = \sum_{i=1}^{d-1} \int_0^{\rho_t} \left\{ |\nabla \gamma J_i|^2 - \langle \mathcal{R}(\gamma, J_i) J_i, \gamma \rangle \right\}(s) ds,
\]

(4.7)

where \( \mathcal{R} \) is the curvature tensor. Let

\[
\tilde{J}_i(s) = \left( \frac{s}{\rho_t} \psi(Y_t) + \frac{\rho_t - s}{\rho_t} \psi(X_t) \right) P_{\gamma(0), \gamma(s)} V_i, \quad 1 \leq i \leq d - 1.
\]

We have \( \tilde{J}_i(0) = J_i(0) \) and \( \tilde{J}_i(\rho_t) = J_i(\rho_t), 1 \leq i \leq i - 1 \). By the index lemma,

\[
I \leq \sum_{i=1}^{d-1} \int_0^{\rho_t} \left\{ |\nabla \gamma \tilde{J}_i|^2 - \langle \mathcal{R}(\gamma, \tilde{J}_i) \tilde{J}_i, \gamma \rangle \right\}(s) ds
\]

\[
\leq (d - 1) \|\nabla \psi\|^2_{L^\infty} \rho_t - \frac{1}{\rho_t^2} \int_0^{\rho_t} \left\{ s \psi(Y_t) + (\rho_t - s) \psi(X_t) \right\}^2 \text{Ric}(\gamma(s), \gamma(s)) ds.
\]

(4.8)
Moreover, 

\[ \psi(X_t)^2 \langle Z(X_t), \nabla \rho(\cdot, Y_t)(X_t) \rangle + \psi(Y_t)^2 \langle Z(Y_t), \nabla \rho(X_t, \cdot)(Y_t) \rangle \]

\[ = \frac{1}{\rho_t^2} \int_0^{\rho_t} d\langle \psi(Y_t) + (\rho_t - s)\psi(X_t) \rangle (Z(\gamma(s)), \dot{\gamma}(s))ds \]

\[ = \frac{1}{\rho_t^2} \int_0^{\rho_t} (s\psi(Y_t) + (\rho_t - s)\psi(X_t))^2 (\nabla \dot{\gamma} Z \circ \gamma, \dot{\gamma}(s))ds \]

\[ + 2\int_0^{\rho_t} (\psi(Y_t) - \psi(X_t)) (s\psi(Y_t) + (\rho_t - s)\psi(X_t))ds \]

\[ \leq 1 \rho_t^2 \int_0^{\rho_t} (s\psi(Y_t) + (\rho_t - s)\psi(X_t))^2 (\nabla \dot{\gamma} Z \circ \gamma, \dot{\gamma}(s))ds \]

\[ + 2\|Z\|_\infty \|\psi\|_\infty \|\nabla \psi\|_\infty \rho_t. \] (4.9)

Finally, we have

\[ \langle \nabla \rho(X_t, \cdot)(Y_t), P_{X_t, Y_t} \Phi_t d\tilde{B}_t \rangle = \langle P_{Y_t, X_t} \nabla \rho(X_t, \cdot)(Y_t), \Phi_t d\tilde{B}_t \rangle = \]

\[ = -\langle \nabla \rho(\cdot, Y_t)(X_t), \Phi_t d\tilde{B}_t \rangle. \]

Combining this with (4.6), (4.7), (4.8) and (4.9), we arrive at

\[ d\rho(X_t, Y_t) \leq \sqrt{2} (\psi(X_t) - \psi(Y_t)) (\nabla \rho(\cdot, Y_t)(X_t), \Phi_t d\tilde{B}_t) \]

\[ + K_\psi \rho(X_t, Y_t) dt + \sqrt{2} \|\psi\|_\infty \|\beta_t\| dt. \]

Then

\[ M_t := \sqrt{2} \int_0^t e^{-K_\psi s} (\psi(X_s) - \psi(Y_s)) (\nabla \rho(\cdot, Y_s)(X_s), \Phi_s d\tilde{B}_s) \]

is a \( \mathbb{Q} \)-martingale such that

\[ \rho(X_t, Y_t) \leq e^{K_\psi t} M_t + \sqrt{2} e^{K_\psi t} \int_0^t e^{-K_\psi s} \|\psi\|_\infty \|\beta_s\| ds, \quad t \in [0, T]. \] (4.10)

So, by the Doob inequality we obtain
\[ h_t := \mathbb{E}_Q \max_{s \in [0,t]} \rho(X_s, Y_s)^2 \]
\[ \leq (1 + R)e^{2K_y t} \mathbb{E}_Q \max_{s \in [0,t]} M_s^2 ds \]
\[ + 2\|\psi\|_\infty^2 (1 + R^{-1}) e^{2K_y t} \mathbb{E}_Q \left( \int_0^t e^{-K_y s} \|\beta_s\| ds \right)^2 \]
\[ \leq 4(1 + R)e^{2K_y t} \mathbb{E}_Q M_t^2 + (1 + R^{-1}) \|\psi\|_\infty^2 \frac{e^{2K_y t} - 1}{K_y} \int_0^t \mathbb{E}_Q \|\beta_s\|^2 ds \]
\[ \leq 4(1 + R)\|\nabla \psi\|_\infty^2 e^{2K_y t} \int_0^t e^{-2K_y s} h_s ds \]
\[ + (1 + R^{-1}) \|\psi\|_\infty^2 \frac{e^{2K_y t} - 1}{K_y} \int_0^t \mathbb{E}_Q \|\beta_s\|^2 ds \]
for any \( R > 0 \). Since \( e^{-2K_y s} \) is decreasing in \( s \) while \( h_s \) is increasing in \( s \), by the FKG inequality we have
\[ \int_0^t e^{-2K_y s} h_s ds \leq \left( \frac{1}{t} \int_0^t e^{-2K_y s} ds \right) \int_0^t h_s ds \leq \frac{1}{2K_y t} \int_0^t h_s ds. \]

Therefore,
\[ h_t \leq 2(1 + R)\|\nabla \psi\|_\infty^2 \frac{e^{2K_y t} - 1}{K_y} \int_0^t h_s ds + (1 + R^{-1}) \|\psi\|_\infty^2 \frac{e^{2K_y t} - 1}{K_y} \int_0^t \mathbb{E}_Q \|\beta_s\|^2 ds \]
holds for \( t \in [0,T] \). Since \( h_0 = 0 \), this implies that
\[ \mathbb{E}_Q \max_{t \in [0,T]} \rho(X_t, Y_t)^2 = h_T \]
\[ \leq (1 + R^{-1}) \|\psi\|_\infty^2 \frac{e^{2K_y T} - 1}{K_y} \exp \left( 2(1 + R)\|\nabla \psi\|_\infty^2 \frac{e^{2K_y T} - 1}{K_y} \right) \int_0^T \mathbb{E}_Q \|\beta_s\|^2 ds. \]

Combining this with (4.5) and (3.9), we complete the proof. \( \square \)

**Theorem 4.2.** In the situation of Theorem 4.1,
\[ W_{2,\rho_*} (\Pi_{\mu,\psi}^T, \Pi_{\nu,\psi}^T) \leq 2\rho(K_y + \|\nabla \psi\|_\infty^2)T W_{2,\rho}(\mu, \nu), \quad \mu, \nu \in \mathcal{P}(M), T > 0. \]

**Proof.** As explained in the proof of “(6) \Rightarrow (5)”, we only consider \( \mu = \delta_x \) and \( \nu = \delta_y \). Let \( X_t \) solve (4.2) with \( X_0 = x \), and let \( Y_t \) solve, instead of (4.4),
\[ dY_t = \sqrt{2} \psi(Y_t) P_{X_t,Y_t} \Phi t d\tilde{B}_t + \psi^2(Y_t) Z(Y_t) dt + N(Y_t) d\tilde{U}_t, \quad Y_0 = y. \]
Then, repeating the proof of Theorem 4.1 we have, instead of (4.10),
\[ \rho(X_t, Y_t) \leq e^{K_y t}(M_t + \rho(x, y)), \quad t \geq 0 \quad (4.11) \]
holds for
\[ M_t := \sqrt{2} \int_0^t e^{-K_{\psi,s}(\psi(X_s) - \psi(Y_s))} \langle \nabla \rho(\cdot, Y_s)(X_s), \Phi_s dB_s \rangle. \]

So,
\[ \mathbb{E}\rho(X_1, Y_2)^2 \leq e^{2K_{\psi,t}} \mathbb{E} \left\{ \rho(x, y)^2 + 2\| \nabla \psi \|_{X_c}^2 \int_0^t e^{-2K_{\psi,s}} \mathbb{E}\rho(X_s, Y_s)^2 \right\}, \]
which implies
\[ \mathbb{E}\rho(X_1, Y_2)^2 \leq e^{2(K_{\psi} + \| \nabla \psi \|_{X_c}) t} \rho(x, y)^2. \]
Combining this with (1.1) and the Doob inequality, we arrive at
\[
W_{2,\rho_{\infty}}(\Pi_{\rho_{\psi},\phi}^T, \Pi_{\rho_{\psi},\phi}^T)^2 \leq \mathbb{E} \max_{t \in [0,T]} \rho(X_t, Y_t)^2 \leq e^{2K_{\psi,T}} \mathbb{E} \max_{t \in [0,T]} (M_t + \rho(x, y))^2 \\
\leq 4e^{2K_{\psi,T}} \mathbb{E} (M_T + \rho(x, y))^2 = 4e^{2K_{\psi,T}} \left( \mathbb{E} (M_T^2 + \rho(x, y)^2) \right) \\
= 4e^{2K_{\psi,T}} \left( \rho(x, y)^2 + 2\| \nabla \psi \|_{X_c}^2 \int_0^T e^{-2K_{\psi,t}} \mathbb{E}\rho(X_t, Y_t)^2 dt \right) \\
\leq 4e^{2(K_{\psi} + \| \nabla \psi \|_{X_c}) T} \rho(x, y)^2.
\]
This implies the desired inequality for \( \mu = \delta_x \) and \( \nu = \delta_y \).

5 Extensions to non-convex manifolds

As explained in the end of Section 1, combining Theorem 1.1 with a proper conformal change of metric, we are able to establish the following transportation-cost inequality on a class of manifolds with non-convex boundary.

**Theorem 5.1.** Let \( \partial M \neq \emptyset \) with \( \| \geq -\sigma \) for some constant \( \sigma > 0 \), and let (1.1) hold for some \( K \in \mathbb{R} \). Then for any \( f \in C_0^\infty(M) \) with \( f \geq 1 \) and \( N \log f \mid_{\partial M} \geq \sigma \), and for any \( \mu \in \mathcal{P}(M) \),
\[
W_{2,\rho_{\infty}}(\Pi_{\rho_{\mu},\phi}^T, \Pi_{\rho_{\mu},\phi}^T)^2 \leq 2\| f \|_{X_c}^2 c(T, f) \Pi_{\rho_{\mu}}^T(F \log F), \quad F \geq 0, \Pi_{\rho_{\mu}}^T(F) = 1
\] holds for
\[
c(T, f) = \inf_{R > 0} \left\{ \left( 1 + R^{-1} \right) \frac{e^{2K_{\psi,T}} - 1}{\kappa_f} \exp \left[ 2(1 + R) \| \nabla f \|_{X_c} \frac{e^{2K_{\psi,T}} - 1}{\kappa_f} \right] \right\},
\]
where
\[
\kappa_f = 5\| f \|_{X_c} \| \nabla f \|_{X_c} \| Z \|_{X_c} + \left\{ 3d - 5 + (d - 3)^+ \right\} \| \nabla f \|_{X_c}^2 + \| (Kf^2 - f \Delta f)^+ \|_{X_c}.
\]
In particular,
\[
W_{2,\rho_{\infty}}(\Pi_{\rho_{\mu},\phi}^T, \Pi_{\rho_{\mu},\phi}^T)^2 \leq 2\| f \|_{X_c}^2 c(T, f) \Pi_{\rho_{\mu}}^T(F \log F), \quad o \in M, F \geq 0, \Pi_{\rho_{\mu}}^T(F) = 1.
\]
Proof. Let $f \in C^\infty_c(M)$ such that $f \geq 1$. Since $1 \geq -\sigma$ and $N \log f|_{\partial M} \geq \sigma$, by [21, Lemma 2.1] the boundary $\partial M$ is convex under the new metric

$$\langle \cdot, \cdot \rangle' = f^{-2}\langle \cdot, \cdot \rangle.$$ 

Let $\Delta'$ and $\nabla'$ be induced by the new metric. Then (see formula (2.2) in [14])

$$L = f^{-2}(\Delta' + Z'), \quad Z' := f^2Z + \frac{d-2}{2} \nabla f^2.$$

Let $\text{Ric}'$ be the Ricci curvature induced by the new metric, we have (cf. formula (3.2) in [6])

$$\text{Ric}' = \text{Ric} + (d-2)f^{-1}\text{Hess}_f + \left(f^{-1}\Delta f - (d-3)|\nabla \log f|^2\right)\langle \cdot, \cdot \rangle. \quad (5.1)$$

Since the Levi-Civita connection induced by $\langle \cdot, \cdot \rangle'$ satisfies (cf. [3, Theorem 1.59(a)])

$$\nabla'_U V = \nabla_U V - (U, \nabla \log f)V - (V, \nabla \log f)U + \langle U, V \rangle \nabla \log f, \quad U, V \in TM,$$

we have

$$\langle \nabla'_U Z', U \rangle' = f^{-2}\left\{ \langle \nabla_U Z', U \rangle - \langle Z', \nabla \log f \rangle|U|^2 \right\}$$

$$= 2\langle U, \nabla \log f \rangle \langle Z, U \rangle + \langle \nabla_U Z, U \rangle + \frac{d-2}{2f^2} \text{Hess}_f(U, U)$$

$$- \langle Z, \nabla \log f \rangle|U|^2 - \frac{d-2}{2} \langle |\nabla \log f|^2, \nabla \log f \rangle|U|^2$$

$$\leq \langle \nabla_U Z, U \rangle + 3|\nabla \log f| \cdot |Z| \cdot |U|^2 + (d-2)f^{-1}\text{Hess}_f(U, U).$$

Combining this with (5.1), we obtain

$$\text{Ric}'(U, U) - \langle \nabla_U Z', U \rangle'$$

$$\geq \text{Ric}(U, U) - \langle \nabla_U Z, U \rangle + \left\{ f^{-1}\Delta f - (d-3)|\nabla \log f| - 3|Z| \cdot |\nabla \log f| \right\}|U|^2$$

$$\geq -K'(U, U)', \quad U \in TM,$$

where

$$K' = \sup_M\{Kf^2 - f\Delta f + (d-3)|\nabla f|^2 + 3|Z|f|\nabla f| \}. \quad (5.2)$$

Noting that $f \geq 1$, we have

$$\sqrt{\langle Z', Z' \rangle'} = f^{-1}|f^2Z + (d-2)f\nabla f| \leq \|f\|_\infty\|Z\|_\infty + (d-2)\|\nabla f\|_\infty,$$

$$\sqrt{\langle \nabla' f^{-1}, \nabla' f^{-1} \rangle'} = f|\nabla f^{-1}| \leq \|\nabla f\|_\infty. \quad (5.3)$$
Letting $K_\psi$ be defined in Theorem 4.1 for the manifold $(M, \langle \cdot, \cdot \rangle)$ and $L = \psi^2(\Delta' + Z')$ with $\psi = f^{-1}$, we deduce from $f \geq 1$, (5.2) and (5.3) that

$$K_\psi \leq \kappa_f.$$ 

Therefore, $C(T, \psi) \leq c(T, f)$ and thus, Theorem 4.1 implies

$$W_2, \rho'_{\infty}(\Pi^T_{\mu}, \Pi^T_{\nu}) \leq 2\|f\|_{\infty}e^{(\kappa_f + \|\nabla f^{-1}\|_{\infty})^T}W_2, \rho_{\infty}(\mu, \nu), \quad \mu, \nu \in \mathcal{P}(M), T > 0.$$ 

As a consequence of Theorems 5.1 and 5.2, we present below an explicit transportation-cost inequalities for a class of non-convex manifolds.

**Corollary 5.3.** Assume that (1.1) holds for some $K \geq 0$ and the injectivity radius $i_{\partial M}$ of $\partial M$ is strictly positive. Let $\sigma \geq 0$ and $\gamma, k, > 0$ be such that $-\sigma \leq I \leq \gamma$ and $\text{Sect}_M \leq k$. Let

$$0 < r \leq \min \left\{ i_{\partial M}, \frac{1}{\sqrt{k}} \arcsin \left( \frac{\sqrt{k}}{\sqrt{k + \gamma^2}} \right) \right\}.$$ 

(i) The transportation-cost inequality

$$W_2, \rho_{\infty}(F\Pi^T_{\mu}, \Pi^T_{\nu}) \leq (2 + rd\sigma)^2 \frac{e^{2\theta T} - 1}{\theta} \exp \left[ \frac{4(e^{2\theta T} - 1)}{\theta} \right] \Pi^T_{\mu}(F \log F)$$

holds for all $\mu \in \mathcal{P}(M)$ and $F \geq 0$ with $\Pi^T_{\mu}(F) = 1$, where

$$\theta = K \left( 1 + rd\sigma + \frac{r^2d^2\sigma^2}{4} + \frac{d\sigma}{r} \left( 3d - 5 + (d-3)^+ + \frac{d^2}{2} \right) \sigma^2 + 5\|Z\|_{\infty}\sigma \left( 1 + \frac{rd\sigma}{2} \right) \right).$$

In particular,

$$W_2, \rho_{\infty}(F\Pi^T_{\nu}, \Pi^T_{\mu}) \leq (2 + rd\sigma)^2 \frac{e^{2\theta T} - 1}{\theta} \exp \left[ \frac{4(e^{2\theta T} - 1)}{\theta} \right] \Pi^T_{\mu}(F \log F).$$
holds for all $F \geq 0$ with $\Pi^T_\mu (F) = 1$.

(ii) For any $T > 0$ and $\mu, \nu \in P(M)$, 

$$W_{2,\rho^\infty}(\Pi^T_\mu, \Pi^T_\nu) \leq (2 + \sigma r d) e^{(\theta + \sigma^2) T} W_{2,\rho}(\mu, \nu).$$

Proof. Let 

$$h(s) = \cos (\sqrt{k} s) - \frac{\gamma}{\sqrt{k}} \sin (\sqrt{k} s), \quad s \geq 0.$$ 

Then $h$ is the unique solution to the equation 

$$h'' + kh = 0, \quad h(0) = 1, h'(0) = -\gamma.$$ 

Up to an approximation argument presented in the proof of [20, Theorem 1.1], we may apply Theorem 5.1 to 

$$f = 1 + \sigma \varphi \circ \rho_{\partial M},$$ 

where $\rho_{\partial}$ is the Riemannian distance to $\partial M$, which is smooth on $\{ \rho_{\partial M} < i_{\partial M} \}$, and 

$$\alpha = (1 - h(r))^{1-d} \int_0^r (h(s) - h(r))^{d-1} ds,$$ 

$$\varphi(s) = \frac{1}{\alpha} \int_0^s (h(t) - h(r))^{1-d} dt \int_{t \wedge r}^r (h(u) - h(r))^{d-1} du, \quad s \geq 0.$$ 

We have $\varphi(0) = 1, 0 \leq \varphi' \leq \varphi'(0) = 1$. Moreover, as observed in [20, Proof of Theorem 1.1], 

$$\alpha \geq \frac{r}{d}, \quad \varphi(r) \leq \frac{r^2}{2\alpha} \leq \frac{dr}{2}, \quad \Delta \varphi \circ \rho_{\partial M} \geq -\frac{1}{\alpha} \geq -\frac{d}{r},$$ 

So, 

$$\|f\|_\infty \leq 1 + \sigma \varphi(r) \leq 1 + \frac{rd\sigma}{2}, \quad \|
abla f\|_\infty \leq \varphi'(0) = \sigma, \quad \Delta f \geq -\frac{\sigma d}{r}. \quad (5.4)$$ 

Noting that (recall that $K \geq 0$) 

$$\sup(K f^2) \leq K \left(1 + r d\sigma + \frac{r^2 d^2 \sigma^2}{4}\right).$$ 

from (5.4), we conclude that $\kappa_f \leq \theta$. So, (i) follows from (1.5) and (5.1) for $R = 1$, and (ii) follows from Theorem 4.2 and (5.4).

Framed Sheaves over Treefolds
and Symmetric Obstruction Theories

Dragos Oprea

Received: September 20, 2012
Communicated by Edward Frenkel

Abstract. We note that open moduli spaces of sheaves over local Calabi-Yau surface geometries framed along the divisor at infinity admit symmetric perfect obstruction theories. We calculate the corresponding Donaldson-Thomas weighted Euler characteristics (as well as the topological Euler characteristics). Furthermore, for blowup geometries, we discuss the contribution of exceptional curves.

2010 Mathematics Subject Classification: 14N35, 14D20
Keywords and Phrases: Moduli spaces of sheaves, Donaldson-Thomas invariants

1 Introduction

Moduli spaces of sheaves over threefolds admit virtual fundamental classes in a lot of examples, yielding Donaldson-Thomas invariants [T]. The rank 1 case is particularly interesting, bearing connections with virtual curve counts [MNOP].

In this note, we study open moduli spaces of higher rank sheaves over local Calabi-Yau surface geometries, framed along the divisor at infinity. We prove that the moduli spaces admit symmetric perfect obstruction theories, and in this context, we compute the ensuing Donaldson-Thomas Euler characteristics. In addition, we find the topological Euler characteristics of the compactified moduli spaces of framed modules. We also discuss a “blowup” formula. Finally, we point out other geometries which can be studied by the same methods.

This way, we extend previously known results in two directions 1.

1 The search for such generalizations motivated our interest this topic.
(i) First, there is quite a bit of literature on moduli spaces of framed sheaves over surfaces. An exhaustive survey is not our intention here, but we refer the reader to [BPT], [N] for calculations which we partially carry out in the higher dimensional setting, and also for a more comprehensive bibliography.

(ii) Second, as suggested above, we partially generalize to higher rank results about the Hilbert scheme of points over threefolds. For these, the Donaldson-Thomas Euler characteristics, in the form needed here, were calculated in [BF].

2 Framed sheaves over local Calabi-Yau surface geometries

We now detail the discussion. Let $S$ be a smooth complex projective surface, and let $X^o$ denote the total space of the canonical bundle $K_S \to S$. We are concerned with moduli spaces of sheaves over the open Calabi-Yau threefold $X^o$. The noncompact geometry does not allow for a good moduli space of semistable sheaves. Instead, we will consider the compact threefold $\pi: X = \mathbb{P}(K_S + \mathcal{O}_S) \to S$. This comes equipped with two divisors $S_\infty = \mathbb{P}(K_S + 0)$ and $S_0 = \mathbb{P}(0 + \mathcal{O}_S)$ corresponding to the summands $K_S$ and $\mathcal{O}_S$. Clearly, $X \setminus S_\infty = X^o$. We form the moduli space $\mathfrak{M}_n$ of semistable framed modules $(E, \phi)$ of rank $r$ with

$$c_1(E) = c_2(E) = 0, \quad \chi(F) = N := r\chi(\mathcal{O}_S) - n,$$

with a non-zero framing over $S_\infty$:

$$\phi: E \to \mathcal{O}_{S_\infty} \otimes \mathbb{C}^r.$$

The moduli space $\mathfrak{M}_n$ was constructed in [HL]. Semistability was defined with respect to a polynomial $\delta$ of degree $\leq 2$ with positive leading coefficient, as well as an ample divisor $H$ on $X$. We will pick $H = \pi^*H_0 + \epsilon c_1(\mathcal{O}_S(1))$, for an ample divisor $H_0$ on $S$ and a sufficiently small rational $\epsilon > 0$. By definition, $(E, \phi)$ is semistable provided that

(i) for all proper subsheaves $F$ of $E$, the Hilbert polynomials satisfy

$$P_F - \delta \leq \frac{\text{rk}F}{\text{rk}E}(P_E - \delta);$$
(ii) if $F$ is contained in the kernel of $\phi$, then

$$P_F \leq \frac{\text{rk} F}{\text{rk} E} (P_E - \delta).$$

Semistable framed modules admit Harder-Narasimhan filtrations, yielding the notion of $S$-equivalence. There is a projective moduli space $\mathcal{M}_n$ of $S$-equivalence classes of framed modules, cf. [HL].

We will consider the open subset

$$\mathcal{M}_n^o \hookrightarrow \mathcal{M}_n$$

corresponding to what are called framed sheaves in [L], [N]. These are stable framed modules $(E, \phi)$ such that

(iii) $E$ is torsion free, locally free near $S_\infty$, and $\phi$ is an isomorphism along $S_\infty$.

Over curves and certain surfaces and for special framings, the stability conditions (i) and (ii) are automatic for the framed sheaves of (iii), cf. [BM], but for threefolds stability is not yet known to follow on general grounds.

**Example** We describe the moduli space in perhaps the simplest example, that of the Hilbert polynomial

$$P_E = P_{\mathcal{O}_X} - \ell.$$ 

Intuitively, in this case we should get the Hilbert scheme of points. This is not entirely obvious because framed modules are not required to be torsion free and because of the stability condition. The exact description will be determined by comparing $\delta$ to the polynomial

$$\Delta = \chi(mH|_{S_\infty}) = \frac{m^2 H^2}{2} + \text{l.o.t.}$$

To avoid strictly semistables, we assume that $\Delta - \delta$ is not a constant $a$ with $0 \leq a \leq \ell$.

The sheaves $E$ in the moduli space have rank 1 and can be written in the form

$$0 \to T \to E \to E^\circ \to 0$$

where $T$ is torsion and $E^\circ$ is torsion free. In fact,

$$E^\circ = I_Z \otimes L$$

for some line bundle $L \to X$, and some subscheme $Z$ of dimension at most 1. Now, by stability, or using Lemma 1.2 of [HL], the kernel $K$ of the restricted framing

$$\phi_\infty : T \to \mathcal{O}_{S_\infty}$$
must satisfy
\[ p_K \leq 0 \implies K = 0. \]
Therefore \( \phi_\infty \) gives an inclusion of the torsion module \( T \) into the framing \( \mathcal{O}_{S_\infty} \), showing that
\[ T = 0 \text{ or } T = i_*(I_W \otimes M), \]
for some line bundle \( M \) over \( i: S_\infty \to X \), and a subscheme \( W \subset S_\infty \) of dimension zero.

In the first case, since \( c_1(E) = c_2(E) = 0 \), we must have \( c_1(L) = 0 \) and \( Z \) is zero dimensional. We claim that \( L = \mathcal{O}_X \). Indeed, \( L \) restricts trivially to the fibers of \( X \to S \), hence it must be a pullback
\[ L = \pi^* N \]
of a degree zero line bundle \( N \) on \( S \). The framing condition implies that there must exist a nonzero morphism \( N \to \mathcal{O}_S \), hence \( N \) must be trivial. Therefore, up to isomorphisms, the only framed modules are
\[(E, i): I_Z \to \mathcal{O}_{S_\infty} \]
for zero dimensional subschemes \( Z \) of length \( \ell \). We analyze semistability. The kernel of \( i \) takes the form \( I_U(-S_\infty) \) for some zero dimensional scheme \( U \). Thus, we must have
\[ \chi(I_U(mH - S_\infty)) \leq \chi(mH) - \ell - \delta \iff \ell - \ell(U) \leq \Delta - \delta. \]
If \( \Delta - \delta \) has negative leading term, the inequality cannot be satisfied. If \( \Delta - \delta \) has positive leading term, then the inequality is automatic and stability follows. Hence, the moduli space is either empty, or isomorphic to \( X[\ell] \). \(^2\)

We claim the second case cannot occur under our assumptions. If it did, then
\[ 0 \to i_*(I_W \otimes M) \to E \to L \otimes I_Z \to 0. \]
Calculating the Chern class \( c_1(E) = 0 \), we find
\[ L = \mathcal{O}(-S_\infty) \otimes \pi^* N, \]
for some degree 0 line bundle \( N \) over \( S \). Therefore
\[ 0 \to i_*(I_W \otimes M) \to E \to I_Z(-S_\infty) \otimes \pi^* N \to 0, \ \phi: E \to \mathcal{O}_{S_\infty}. \]

\(^2\)We also remark here that if \( \Delta - \delta = a \) for some \( a \in \{0, \ldots, \ell\} \), then there are strictly semistable framed modules. Indeed, pairs of subschemes \( Z^0 \) of \( X^0 \) and \( Z_\infty \) of \( S_\infty \) with \( \ell(Z_\infty) = a \) yield the strictly semistable framed modules \( (I_Z(-S_\infty), 0) \oplus (i_* I_{Z_\infty/S_\infty}, \ell) \).
We already argued above that the restriction $\phi_\infty$ of $\phi$ to the torsion module $i_*(I_W \otimes M)$ must be injective. Since $\phi_\infty \neq 0$, there must exist a non-zero morphism $M \to \mathcal{O}_S$, hence $M'$ must be effective. Since $c_2(E) = 0$, we have

$$\iota_* c_1(M) = [Z].$$

Therefore, $M$ is trivial and $Z$ is of dimension zero. The Hilbert polynomial gives

$$\ell(Z) + \ell(W) = \ell.$$

Furthermore, up to scalars, $\phi_\infty$ must be the natural inclusion. Semistability implies that

$$P_{i_* I_W} - \delta \leq 0 \implies \Delta - \delta \leq \ell(W).$$

Since $\phi_\infty$ is the natural inclusion, the image of $\phi$ in $\mathcal{O}_{S_\infty}$ must be the ideal sheaf $I_U$ of a scheme $U \subset W$. Let $K$ be the kernel of $\phi$. We have

$$P_K = P_E - P_{i_* I_U} = P_E - (\Delta - \ell(U)).$$

Semistability implies

$$P_K \leq P_E - \delta \implies \Delta - \delta \geq \ell(U).$$

Therefore, we conclude that

$$\Delta - \delta = a$$

for some constant $a$ such that

$$\ell(W) \geq a \geq \ell(U).$$

In particular $0 \leq a \leq \ell$ which contradicts our assumption.

To summarize, when $\Delta - \delta$ is not equal to a constant between $0$ and $\ell$, we obtain the following description of the moduli space:

(a) if (the leading term of) $\Delta - \delta < 0$, then we get $\emptyset$;

(b) if (the leading term of) $\Delta - \delta > 0$, then the moduli space is the Hilbert scheme $X[^\ell].$

3 Obstruction theory

We note now that the obstruction theory of framed sheaves is symmetric. To this end, we assume that $\delta$ is good, i.e. it satisfies the following conditions:

- if $\deg \delta = 0$, then $\delta > (r - 1)n$;

- if $\deg \delta = 2$, the quadratic term of $\delta$ is sufficiently small compared to that of $\Delta$. 

Documenta Mathematica 18 (2013) 323–342
In particular, any $\delta$ of degree 1 is good for all $n$.

**Theorem 1.** When $\delta$ is good, the moduli space $\mathcal{M}_n^0$ admits a symmetric perfect obstruction theory at the stable points $(E, \phi)$.

**Proof.** The deformation theory of stable framed sheaves was worked out in [HL], [S]. Write $$(\mathcal{E}, \Phi) \rightarrow \mathcal{M}_n^0 \times X$$
for the universal family, which exists by [HL], and let $p$ and $q$ be the natural projections. The complex
$$\mathbf{F} = R^p_\ast R\mathcal{H}om(\mathcal{E}(-S_\infty), \mathcal{E} \otimes q^\ast K_X)[2]$$
is an obstruction theory over $\mathcal{M}_n^0$. The obstruction theory is symmetric in the sense that there is a symmetric isomorphism
$$\mathbf{F} \rightarrow \mathbf{F}^\vee[1].$$
This is a consequence of Grothendieck duality and of the crucial observation that
$$K_X = \mathcal{O}(-2S_\infty).$$
The calculation of the canonical bundle standardly follows from the Euler sequence of the projective bundle $X$.

The obstruction theory is perfect with amplitude contained in $[-1, 0]$. Indeed, the amplitude is clearly contained in $[-2, 1]$. By symmetry, it suffices to explain that the degree $-2$ term is zero. In turn, this is implied by the vanishing
$$\text{Hom}(E, E(-S_\infty)) = 0$$
which holds for all sheaves $E$ in $\mathcal{M}_n^0$. Indeed, assuming there is a non-zero morphism
$$E \rightarrow E(-S_\infty),$$
we let $K$ and $I$ denote its kernel and image, and write $r_K$ and $r_I$ for their ranks. We have $r_I > 0$. By stability
$$P_K - \delta \leq \frac{r_K}{r}(P_E - \delta), \quad P_I(S_\infty) - \delta \leq \frac{r_I}{r}(P_E - \delta).$$
Considering the quadratic terms of these inequalities, we obtain
$$c_1(K) \cdot H^2 \leq \delta_0 \left(1 - \frac{r_K}{r}\right), \quad c_1(I) \cdot H^2 + r_I S_\infty \cdot H^2 \leq \delta_0 \left(1 - \frac{r_I}{r}\right),$$
where $\delta_0$ is half the leading term of $\delta$. We also have
$$c_1(K) + c_1(I) = 0.$$\[1\]
Adding, we obtain
$$r_I S_\infty \cdot H^2 \leq \delta_0$$
which is impossible when the leading term $\delta_0 < S_\infty \cdot H^2$ is sufficiently small. This completes the proof.  \[QED\]
Example. We determine the obstruction theory for the previous example. We consider case (b) corresponding to $\Delta - \delta > 0$, $\Delta - \delta$ does not equal a constant $a$ with $0 \leq a \leq \ell$. The tangent space at the ideal sheaf $I_Z$ was found in [HL] to be

$$T_Z \mathcal{M} = \text{Ext}^1(I_Z, [I_Z \to \mathcal{O}_{S_\infty}]).$$

This can be calculated from the exact triangle

$$[I_Z \to \mathcal{O}_{S_\infty}] \to [\mathcal{O}_X \to \mathcal{O}_{S_\infty}] \cong \mathcal{O}(-S_\infty) \to \mathcal{O}_Z.$$

We have

$$\text{Ext}^0(I_Z, \mathcal{O}_X(-S_\infty)) = \text{Ext}^3(\mathcal{O}_X, I_Z(-S_\infty))^\vee = H^3(I_Z(-S_\infty))^\vee = H^3(\mathcal{O}_X(-S_\infty))^\vee = 0,$$

and similarly for $\text{Ext}^1$. From the exact triangle, we obtain

$$0 \to \text{Ext}^0(I_Z, \mathcal{O}_Z) \cong T_Z X^{[\ell]} \to T_Z \mathcal{M} \to 0.$$

In particular, this agrees with the identification

$$\mathcal{M} \cong X^{[\ell]}.$$

Thus, by symmetry, the obstruction theory of $\mathcal{M}$ coincides with the usual obstruction theory for the Hilbert scheme only along the open part $(X^\circ)^{[\ell]}$.

4 Calculations

Symmetric perfect obstruction theories have associated Behrend functions [B]. In particular, the open moduli space

$$\mathcal{M}^\circ_n \hookrightarrow \mathcal{M}_n$$

is endowed with a constructible function

$$\nu : \mathcal{M}^\circ_n \to \mathbb{Z}.$$

We will calculate the Donaldson-Thomas weighted Euler characteristic

$$\tilde{\chi}(\mathcal{M}_n^\circ) = \sum_k k \chi(\nu^{-1}(k)).$$

Since the obstruction theory is not perfect symmetric over the boundary, these weighted Euler characteristics do not calculate intersection theoretic Donaldson-Thomas invariants of $\mathcal{M}_n$.  

**Documenta Mathematica 18 (2013) 323–342**
4.1 Virtual localization

Our computation is via equivariant localization. The following result was proved in [BF] for torus actions with isolated fixed points, and in [LQ] in arbitrary generality. Let $\mathcal{M}$ be a moduli space admitting a $\mathbb{C}^*$-action compatible with the symmetric perfect obstruction theory. Then the fixed point set $\mathcal{M}^{\mathbb{C}^*}$ also inherits a symmetric perfect obstruction theory. Furthermore, the Behrend functions of $\mathcal{M}$ and $\mathcal{M}^{\mathbb{C}^*}$ at torus fixed points $p$ are related by

$$\nu_{\mathcal{M}}(p) = (-1)^{\epsilon_p} \nu_{\mathcal{M}^{\mathbb{C}^*}}(p),$$

where $\epsilon_p$ is given by the difference in the dimension of the Zariski tangent spaces

$$\epsilon_p = \dim T_p \mathcal{M} - \dim T_p \mathcal{M}^{\mathbb{C}^*}.$$

This observation is used in [LQ] as follows. The torus acts on the subscheme

$$\{ p \in \mathcal{M} \setminus \mathcal{M}^{\mathbb{C}^*} : \nu_{\mathcal{M}}(p) = k \}$$

with no fixed points, hence its Euler characteristic must be zero, cf. [LY]. Therefore,

$$\chi(\{ p \in \mathcal{M} : \nu_{\mathcal{M}}(p) = k \}) = \chi(\{ p \in \mathcal{M}^{\mathbb{C}^*} : \nu_{\mathcal{M}}(p) = k \})$$

yielding

$$\tilde{\chi}(\mathcal{M}) = \sum_k k \chi(\{ p \in \mathcal{M}^{\mathbb{C}^*} : \nu_{\mathcal{M}}(p) = k(-1)^{\epsilon_p} \}).$$

We will apply these remarks to the action of $\mathbb{C}^*$ on $\mathcal{M}_n$ induced by the scaling action in the fibers of the projective bundle $X \to S$ and the scaling action on the framing coming from a generic embedding

$$\mathbb{C}^* \hookrightarrow \text{GL}_r.$$

We will find the torus fixed points in $\mathcal{M}_n$.

**Lemma 2.** Assume $\delta$ is good. The $\mathbb{C}^*$-fixed framed modules in $\mathcal{M}_n$ take the form

$$E = \bigoplus_{i=1}^r I_{Z_i}$$

where $Z_i$ are zero dimensional subschemes of $X$ invariant under the action of the torus, of total length $n$. The framing $\phi$ is the natural composition $E \hookrightarrow \mathcal{O}_X^r \to \mathcal{O}_{S,\infty}^r$.

**Proof.** We first prove that all invariant framed modules are torsion free. Indeed, the torsion module $T$ of $E$ is $\mathbb{C}^*$-fixed. By stability, the framing $\phi$ gives a $\mathbb{C}^*$-invariant injection

$$\phi_\infty : T \hookrightarrow \mathcal{O}_{S,\infty} \otimes \mathbb{C}^r.$$
Therefore, the torsion module splits
\[ T = \bigoplus_{j=1}^r i_*(I_{W_j} \otimes M_j), \]
for zero dimensional subschemes \( W_j \) of \( S_\infty \) and line bundles \( M_j \) over \( S_\infty \). Again by stability applied to the torsion submodule \( T \) we find
\[ p_T - \delta \leq 0 \implies \ell \cdot H^2 \cdot S_\infty \leq \delta_0 \]
where \( \delta_0 \) is half the quadratic coefficient of \( \delta \). By assumption, we may take \( \delta_0 < H^2 \cdot S_\infty \), implying that \( \ell = 0 \) and showing that the torsion module vanishes.

Now, since \( E \) is torsion free and \( \mathbf{C}^*_\text{-}\text{invariant} \), the argument of [BPT] shows that
\[ E = \bigoplus_{i=1}^r I_{Z_i} \otimes L_i \]
where \( L_i \) are line bundles over \( X \) and \( Z_i \) are subschemes of dimension at most 1. The subschemes \( Z_i \) must be torus invariant. Since \( c_1(E) = c_2(E) = 0 \), we find
\[ \sum c_1(L_i) = 0 \]  \hspace{1cm} (1)
and furthermore
\[ \sum_{i=1}^r c_1(L_i)^2 = 2 \sum_{i=1}^r [Z_i]. \]  \hspace{1cm} (2)

Since the framed module \( (E, \phi) \) is semistable, for all submodules \( F \) of \( E \) of positive rank we must have
\[ \frac{c_1(F) \cdot H^2 - \delta_0}{\text{rk } F} \leq \frac{c_1(E) \cdot H^2 - \delta_0}{\text{rk } E}. \]
Taking \( F = I_{Z_i} \otimes L_i \) we find
\[ c_1(L_i) \cdot H^2 \leq \delta_0 \left(1 - \frac{1}{r}\right). \]

Now, since \( \delta_0 \) is sufficiently small compared to the denominator of the rational divisor \( H \), we conclude
\[ c_1(L_i) \cdot H^2 \leq 0. \]
In fact, \( c_1(L_i) \cdot H^2 = 0 \) for all \( i \), because of (1). We argue that \( L_i \) are trivial and \( Z_i \) are zero dimensional.

Write
\[ c_1(L_i) = \pi^* D_i + d_i \zeta, \]
where \( D_i \) are divisors on the surface \( S \) and \( \zeta = c_1(O_p(1)) \). We calculate
\[ \sum_i c_1(L_i)^2 = \pi^* \left( \sum_i D_i^2 \right) + 2 \sum_i d_i (\pi^* D_i \cdot \zeta) + (\sum_i d_i^2) \zeta^2 = 2 \sum_i [Z_i]. \]  \hspace{1cm} (3)
Set
\[ M = 2 \sum_i d_i D_i - \left( \sum_i d_i^2 \right) K_S. \]
Using
\[ \zeta^2 + K_S \cdot \zeta = 0, \]
we conclude from (3) that
\[ \pi^* \left( \sum_i D_i^2 \right) + \pi^* M \cdot \zeta = 2 \sum_i [Z_i]. \] (4)

Pushing (4) forward under \( \pi \) we find
\[ M = 2 \sum_i \pi_* [Z_i]. \]

As a consequence, \( M \) is effective. The requirement that the slopes of \( L_i \) are trivial translates into the condition
\[ (\pi^* D_i + d_i \zeta)(\pi^* H_0 + \epsilon \zeta)^2 = 0 \]
which rewrites as
\[ (D_i - d_i K_S) \cdot \Sigma = -d_i \]
where
\[ \Sigma = \frac{\epsilon(2H_0 - \epsilon K_S)}{H_0^2} \]
is an ample rational curve class on \( S \) for small \( \epsilon \). Write
\[ F_i = D_i - d_i K_S \]
so that
\[ F_i \cdot \Sigma = -d_i. \]

Since
\[ M = 2 \sum_i d_i F_i + \left( \sum_i d_i^2 \right) K_S \]
is effective, its intersection with \( \Sigma \) must be positive. This gives
\[ -2 \sum_i d_i^2 + \left( \sum_i d_i^2 \right) K_S \cdot \Sigma \geq 0. \]
For small \( \epsilon \) we have \( K_S \cdot \Sigma < 2 \). We conclude from here that \( d_i = 0 \) for all \( i \).
Therefore \( M = 0 \), and by (4) we must have
\[ \pi^* \left( \sum_i D_i^2 \right) = 2 \sum_i [Z_i]. \]
is effective. Note that the left hand side is supported on fibers. Therefore,
\[ \sum_i D_i^2 \geq 0. \] (5)

We moreover proved
\[ F_i \cdot \Sigma = 0 \implies D_i \cdot \Sigma = 0. \]

Since \( \Sigma \) is ample, by Hodge index theorem we have
\[ D_i^2 \leq 0, \]
with equality only if \( D_i \) is numerically equivalent to 0. In fact equality must occur because of (5). This yields \( c_1(L_i) = 0. \) In turn,
\[ L_i = \pi^*N_i \]
for some line bundles \( N_i \to S \) of first Chern class 0. Furthermore, from (3) we find \([Z_i] = 0\) hence \( Z_i \) must be zero dimensional.

Thus
\[ E = \bigoplus_{i=1}^{r} I_{Z_i} \otimes \pi^*N_i, \]
where
\[ \sum \ell(Z_i) = n. \]

Clearly, \( Z_i \) must be torus invariant and \( \phi = \bigoplus \phi_i \) where
\[ \phi_i : I_{Z_i} \otimes \pi^*N_i \to \mathcal{O}_{S_{\infty}}. \]

We next claim that \( \phi_i \neq 0 \) for all \( i \). Indeed, if \( \phi_i = 0 \) for some \( i \), then \( I_{Z_i} \otimes \pi^*N_i \) is in the kernel of \( \phi \), yielding by stability
\[ \chi(I_{Z_i}(mH) \otimes \pi^*N_i) \leq \frac{1}{r} \left( \sum_j \chi(I_{Z_j}(mH) \otimes \pi^*N_j) - \delta \right). \]

This gives
\[ n \geq \ell(Z_i) \geq \frac{n}{r} + \frac{\delta}{r}. \]

This is a contradiction since \( \delta > (r-1)n \). Therefore \( \phi_i \neq 0 \), showing that there exists a non-zero morphism \( N_i \to \mathcal{O}_S. \) Therefore \( N_i \) must be trivial, completing the proof.

Over the open moduli space \( \mathcal{M}^\circ \), the same result holds without any restrictions on \( \delta \):
Lemma 2A. The $C^*$-fixed framed sheaves $E$ in $\mathcal{M}_n^s$ must split

$$E = \bigoplus_{i=1}^r I_{Z_i}$$

where $Z_i$ are zero dimensional subschemes of $X^\circ$ invariant under the action of the torus, of total length $n$.

Proof. By assumption $E$ is torsion free, hence

$$E = \bigoplus_{i=1}^r I_{Z_i} \otimes L_i.$$  

Since the framing is an isomorphism, we conclude $Z_i$ is contained in $X^\circ$ and $L_i$ is trivial on $S_\infty$. Hence,

$$L_i = \mathcal{O}(d_i S_0)$$

for some integers $d_i$. We claim that $d_i = 0$ for all $i$. This in turn implies that $Z_i$ are zero dimensional by using $c_2(E) = 0$.

Assume first that the quadratic term of $\delta$ is sufficiently small. This case is already covered by Lemma 2, but a simpler argument is possible over $\mathcal{M}_n^s$; we record it here for future reference. Indeed, the stability condition applied to $L_i \otimes I_{Z_i}$ gives

$$d_i S_0 \cdot H^2 = c_1(L_i) \cdot H^2 \leq \delta_0 \left(1 - \frac{1}{r}\right) \implies d_i \leq 0.$$  

Since $c_1(E) = 0$, we have $\sum_i d_i = 0$. Hence $d_i = 0$ for all $i$, as claimed.

We now give the general argument. Using that $c_1(E) = c_2(E) = 0$, we find

$$\left(\sum_i d_i^2\right) S_0^2 = 2 \sum_i [Z_i].$$

Assume not all $d_i$ are equal to 0. Since the $Z_i$’s are torus invariant and disjoint from $S_\infty$, their cohomology classes are supported on the surface $S_0$. Using that

$$S_0^2 = (K_S^2) f + \zeta \cdot \pi^* K_S,$$

from equation (6) we find $K_S^2 = 0$. From here, pushing forward under $\pi$, we conclude

$$\left(\sum_i d_i^2\right) K_S = 2 \sum_i \pi_* [Z_i]$$

which is effective. Hence

$$K_S \cdot H_0 \geq 0.$$  

Now, $I_{Z_i}(d_i S_0 - S_\infty)$ is contained in the kernel of $\phi$. Hence by stability

$$(d_i S_0 - S_\infty) \cdot H^2 \leq -\delta_0 \frac{r}{r}.$$
Pick an index $i$ such that $d_i \geq 1$. The above inequality implies

$$(S_0 - S_\infty) \cdot H^2 \leq -\frac{\delta_0}{r} \implies \pi^* K_S \cdot H^2 \leq -\frac{\delta_0}{r}.$$  

However,

$$\pi^* K_S \cdot H^2 = \epsilon \cdot (2H_0 - \epsilon K_S) K_S = 2 \epsilon \cdot K_S \cdot H_0 \geq 0.$$  

Therefore, $K_S \cdot H_0 = \delta_0 = 0$. Since the quadratic term of $\delta$ is 0, the previous paragraph applies, showing that in fact all $d_i = 0$. 

**Lemma 3.** If $\delta$ is good, all torus fixed framed sheaves $E$ in $\mathcal{M}_n$ described above are stable.

**Proof.** Let $F$ be a subsheaf of $E = \oplus I_{Z_i}$ of rank $r'$. Since $F$ is a subsheaf of $O_X$, by Gieseker semistability we have

$$P_F \leq r' \chi(mH) < \frac{r'}{r} P_E + \frac{r - r'}{r} \delta,$$

at least when $r' \neq r$, using that $\delta > (r - 1)n$. When $r' = r$, induction on $r$ yields the claim. For the inductive step, consider the non-zero map $F \to I_{Z_i}$, and write $F'$ for the kernel. Then, apply the induction hypothesis to $F'$ which is contained in $\oplus_{i=1}^{r-1} I_{Z_i}$.

Next, assume $F$ is in the kernel of $\phi$. The kernel of $\phi$ is contained in $O_X(-S_\infty)^r$ (and it is isomorphic to $\oplus_{j} I_{Z_j}(-S_\infty)$ for $E$ in $\mathcal{M}_n^2$). By Gieseker-semistability, we have

$$P_F \leq r' \chi(mH - S_\infty) < \frac{r'}{r} (r \chi(mH) - n - \delta) = \frac{r'}{r} (P_E - \delta),$$

using that $\delta$ is good.

**Lemma 4.** For all torus fixed sheaves $E$ in $\mathcal{M}_n$, we have

$$\dim T_E \mathcal{M}_n \equiv nr \mod 2.$$  

**Proof.** Since $E = \oplus I_{Z_i}$ is stable, the tangent space is calculated in [HL]:

$$T_E \mathcal{M}_n = \text{Ext}^1(E, E(-S_\infty)) = \sum_{i,j} \text{Ext}^1(I_{Z_i}, I_{Z_j}(-S_\infty)).$$

We consider first the contributions of terms corresponding to pairs of indices $(i, j)$ and $(j, i)$ for $i \neq j$:

$$\text{Ext}^1(I_{Z_i}, I_{Z_j}(-S_\infty)) + \text{Ext}^1(I_{Z_j}, I_{Z_i}(-S_\infty))$$
\[ = \text{Ext}^1(I_{Z_i}, I_{Z_j}(-S_\infty)) + \text{Ext}^2(I_{Z_i}, I_{Z_j}(-S_\infty)) \]

by Serre duality. Now, considering the above expression modulo 2 we obtain

\[ \chi(I_{Z_i}, I_{Z_j}(-S_\infty)) + \text{Ext}^0(I_{Z_i}, I_{Z_j}(-S_\infty)) + \text{Ext}^3(I_{Z_i}, I_{Z_j}(-S_\infty)). \]

Next, it is easily seen that \( \text{Ext}^0 \) vanishes, and same for \( \text{Ext}^3 \) by duality. Thus, we are left with

\[ \chi(I_{Z_i}, I_{Z_j}(-S_\infty)) = \chi(O_{X}, O_{Z_i}(-S_\infty)) - \chi(O_{Z_i}, O_{Z_j}) - \chi(O_{Z_j}, O_{X}(-S_\infty)) = \ell(Z_i) + \ell(Z_j) \mod 2. \]

We consider now the terms with \( i = j \):

\[ \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)). \]

This term was already worked out in the deformation theory of Example 1. We obtained

\[ \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)) = \text{Ext}^0(I_{Z_i}, O_{Z_i}) \equiv \ell(Z_i) \mod 2, \]

where for the last congruence we used [BF] or [MNOP]. The lemma follows by collecting the above facts.

We can now put together the calculation of Lemma 4 and the remarks about Behrend functions in Subsection 4.1 to calculate the Donaldson-Thomas Euler characteristic of \( \mathcal{M}^n \). We write \( \mathcal{X}_\ell \) for the subset of the Hilbert scheme of points in \( X^\ell \) which parametrizes torus fixed \( Z \)'s of length \( \ell \). For each partition \( \ell \) into \( r \) parts \( (\ell_1, \ldots, \ell_r) \) with \( \ell_1 + \ldots + \ell_r = n \) we write

\[ \mathcal{X}^\ell = \mathcal{X}^{\ell_1} \times \ldots \times \mathcal{X}^{\ell_r}. \]

Then, \( \mathcal{X}^\ell \) are the \( C^* \)-fixed loci of \( \mathcal{M}^n \). With the convention that

\[ \vec{Z} = (Z_1, \ldots, Z_r) \]

represents an \( r \)-tuple of schemes in \( \mathcal{X}^\ell \), we calculate

\[ \bar{\chi}(\mathcal{M}^n) = \]

\[ = \sum_{\vec{\ell}} \sum_k k \chi(\{ \vec{Z} \in \mathcal{X}^{\ell} : \nu_{\mathcal{X}^{\ell}}(\vec{Z}) = k(-1)^{\ell - \dim \mathcal{T}_{\mathcal{X}^{\ell}}} \}) \]

\[ = (-1)^{(r-1)n} \sum_{\vec{\ell}} \prod_{i=1}^r k_i \chi(\{ Z_i \in \mathcal{X}^{\ell_i} : \nu_{\mathcal{X}^{\ell_i}}(Z_i) = k_i(-1)^{\ell_i - \dim \mathcal{T}_{\mathcal{X}^{\ell_i}}} \}) \]

\[ = (-1)^{(r-1)n} \prod_{i=1}^r \left( \sum_{k} k \chi(\{ Z : \nu_{\mathcal{X}^{\ell_i}}(Z) = k(-1)^{\ell_i - \dim \mathcal{T}_{\mathcal{X}^{\ell_i}}} \}) \right) \]
By applying these results when \( r = 1 \), and using the identification of the rank 1 moduli space with the Hilbert scheme worked out in Example 1, we obtain
\[
\check{\chi}((X^\circ)^{|f|}) = \sum_{k} k\chi(\{Z : \nu X^\circ(Z) = k(-1)^{\ell - \dim T_Z X^\circ}\}).
\]
This yields
\[
\check{\chi}(\mathfrak{M}^\circ_n) = (-1)^{(r-1)n}\sum_{\ell} \check{\chi}((X^\circ)^{|f|_\ell}) \cdots \check{\chi}((X^\circ)^{|f_r|}).
\]
We form the generating series
\[
\sum_n q^n \check{\chi}(\mathfrak{M}^\circ_n) = \left(\sum_{\ell} ((-1)^{(r-1)}q)^{\ell} \check{\chi}((X^\circ)^{|f|_\ell})\right)^r.
\]
Now, from [BF] we lift the calculation
\[
\sum_{\ell} q^{\ell} \check{\chi}((X^\circ)^{|f|}) = M(-q)^{r e(X^\circ)} = M(-q)^{r e(S)};
\]
where \( M(q) \) is the MacMahon function
\[
M(q) = \prod_{k=1}^{\infty} (1 - q^k)^{-k}.
\]
To summarize, for \( \delta \) good, we proved

**Theorem 5.** The following equality holds
\[
\sum_{n \geq 0} q^n \check{\chi}(\mathfrak{M}^\circ_n) = M((-1)^r q)^{r e(S)}.
\] (7)

We are unable to define (and calculate) the virtual motive \([\mathfrak{M}^\circ_n]^{vir}\), as it is done in rank 1 in [BBS] and for surfaces in [N]. This question may deserve further study.

### 4.2 Topological Euler characteristics

Lemma 1 also allows us to calculate the topological Euler characteristics of the compact spaces \( \mathcal{M}_n \) via the localization results of [LY]:
\[
e(\mathfrak{M}_n) = e(\mathfrak{M}_n^C).
\]
The same calculation as above shows that
\[
\sum q^n e(\mathfrak{M}_n) = \left(\sum q^n e(\mathcal{I}_n)\right)^r = M(q)^{r e(X)}
\] (8)
where \( \mathcal{I}_n \cong X_n^{|n|} \) denotes the rank 1 moduli space. The series needed here
\[
\sum q^n e(\mathcal{I}_n) = M(q)^{e(X)}
\]
is computed in [C]. The answer we found is valid whenever \( \delta \) is good.
4.3 Blow-up surfaces

A slightly more complicated example arises by considering blow-up geometries. Indeed, assume that the surface $S$ contains a $(-1)$-curve $C$. Then, $C \hookrightarrow S_0$ is super-rigid in $X$:

$$N_{C/X} = N_{C/S} \oplus N_{S_0/X}|_C = \mathcal{O}_C(-1) \oplus \mathcal{O}_C(-1).$$

We consider the moduli space $\mathfrak{M}_{n,k}$ of rank $r$ modules over $X$ framed at infinity, with numerics

$$c_1 = 0, \quad c_2 = k[C], \quad \chi = r\chi(\mathcal{O}_X) - n.$$ 

In order not to worry about stability, we assume that $\delta$ is good of degree 2. By the argument in the first two paragraphs of Lemma 2A, the torus fixed sheaves in $\mathfrak{M}_{n,k}$ take the form

$$E = \oplus_i I_{Z_i},$$

where $Z_i$ may have at most 1 dimensional components contained in $X^o$. Furthermore,

$$\sum_i [Z_i] = k[C], \quad \sum_i \chi(\mathcal{O}_{Z_i}) = n.$$ 

In fact, $[Z_i] = k_i[C]$ for non-negative integers $k_i$ adding up to $k$. Indeed, after projecting to the blowdown surface $X \to S \to \bar{S}$

the classes of the effective curves $Z_i$ add up to 0, hence they must be trivial. This shows that the components of $Z_i$ are supported on the fibers of $X \to S$ or are contained in the Hirzebruch surface $F = \mathbb{P}(K_S|_C \oplus \mathcal{O}_C) \to C$.

In fact, by torus invariance, all components of $Z_i$ must be supported over fibers or over the zero section $C \hookrightarrow S_0$. Since

$$\sum_i [Z_i] = k[C]$$

contains no fiber classes, or alternatively since the framing must be an isomorphism along $S_{\infty}$, we conclude that $Z_i$ has no support over fibers, hence $[Z_i] = k_i[C]$ as claimed.

We carry out the computation of the Donaldson-Thomas Euler characteristics. In the new setting, for all $\mathbb{C}^*$-fixed sheaves $E$ in $\mathfrak{M}_{n,k}$ we have

$$\dim T_E \mathfrak{M}_{n,k} \equiv rn - k \mod 2.$$
The proof follows that of Lemma 4. The only change is the calculation
\[ \dim \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)) \equiv \chi(O_{Z_{i}}) - k_i \mod 2. \]

To this end, consider the exact sequence
\[ 0 \rightarrow I_{Z_i}(-S_\infty) \rightarrow I_{Z_i} \rightarrow O_{S_\infty} \rightarrow 0. \]
Since the map \( \text{Ext}^0(I_{Z_i}, I_{Z_i}) \rightarrow \text{Ext}^0(I_{Z_i}, O_{S_\infty}) \) is an isomorphism, we obtain the exact sequence
\[ 0 \rightarrow \dim \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)) \rightarrow \text{Ext}^1(I_{Z_i}, I_{Z_i}) \rightarrow \text{Ext}^1(I_{Z_i}, O_{S_\infty}). \]

To find the last group, we use the local to global spectral sequence
\[ H^p(\text{Ext}^q(I_{Z_i}, O_{S_\infty})) \Rightarrow \text{Ext}^{p+q}(I_{Z_i}, O_{S_\infty}). \]
The terms with \( q \geq 1 \) vanish since \( Z_i \) avoids \( S_\infty \), while the \( q = 0 \) terms equal \( H^p(O_S) \). Therefore,
\[ \text{Ext}^1(I_{Z_i}, O_{S_\infty}) = H^1(O_S). \]
From the exact sequence, we conclude
\[ \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)) = \text{Ext}^1(I_{Z_i}, I_{Z_i})_0. \]
The dimension of the last vector space was found in [BB] using Theorem 2 of [MNOP]. The answer is
\[ \text{Ext}^1(I_{Z_i}, I_{Z_i}(-S_\infty)) \equiv \chi(O_{Z_{i}}) - k_i \mod 2 \]
as claimed above.

We form the generating series
\[ \sum_{n,k} \chi(\mathcal{M}^n_{n,k}) q^n v^k = \left( \sum_{n,k} ((-1)^{r-1} q)^n v^k \chi(\mathcal{M}^0_{n,k}) \right)^r \]
where \( \mathcal{M}^0_{n,k} \) denotes the rank 1 framed moduli space. This is isomorphic to the Hilbert scheme. The rank 1 Donaldson-Thomas invariants of super-rigid curves were calculated in [BB]:
\[ \sum_{n,k} q^n v^k \chi(\mathcal{M}^0_{n,k}) = M(-q)^{e(X^\infty)} \cdot \prod_{m=1}^{\infty} (1 - (-q)^{m} v)^{m}. \]
Therefore, we obtain
\[ \sum_{n,k} \chi(\mathcal{M}^0_{n,k}) q^n v^k = M((-1)^r q)^{e(S)} \cdot \prod_{m=1}^{\infty} (1 - ((-1)^r q)^{m} v)^{mr}. \]
4.4 Other geometries

There are other geometries for which the above methods apply. We discuss some of them here. Most straightforwardly, assuming $S_\infty$ is a smooth framing divisor with

$$K_X = -2S_\infty,$$

then our techniques yield

$$\sum_n q^n \tilde{\chi}(\mathcal{M}_n^\infty) = M((-1)^r q)^{\text{re}(X^\infty)}.$$  \hfill (10)

In order to make the proof of Lemma 2A work, we need to assume for instance that the restriction

$$\text{Pic}(X) \cap (H^2)^\perp \to \text{Pic}(S_\infty)$$

is injective. If $X$ is Fano of index 2, this requirement is satisfied by the Lefschetz hyperplane theorem applied to the ample class $S_\infty$. Examples pertinent to this setting include, among others:

- $X$ is a cubic in $\mathbb{P}^4$ or a $(2,2)$ complete intersection in $\mathbb{P}^5$, and $S_\infty$ is a hyperplane section;
- $X$ is a double cover of $\mathbb{P}^3$ branched along a quartic, and $S_\infty$ is the pullback of a hyperplane.

Fano threefolds of index higher than 2 also yield symmetric perfect obstruction theories. This can be checked directly using the well-known classification:

- $X$ is a quadric in $\mathbb{P}^4$ or $X = \mathbb{P}^3$, and $S_\infty$ is a hyperplane section.

In index 3, more examples arise from the curve geometry:

- $X = \mathbb{P}(\mathcal{O}_C + E) \to C$, with $E \to C$ any rank 2 bundle of determinant $\det E = K_C$, and $S_\infty$ the divisor at infinity.

Since the same argument works in all cases above, let us only discuss the rank $r$ sheaves over $\mathbb{P}^3$ framed along the plane at infinity $\mathbb{P}^2 \hookrightarrow \mathbb{P}^3$. Along $\mathcal{M}_n^\infty$, the obstruction theory is symmetric since

$$T_k \mathcal{M}_n^\infty = \text{Ext}^1(E, E(-1)) = \text{Ext}^1(E, E(-3)) = \text{Ext}^2(E, E(-1))^\vee = \text{ob}_E^\infty.$$  

The second isomorphism follows from the short exact sequences

$$0 \to E(-k-1) \to E(-k) \to \mathcal{O}_{\mathbb{P}^2}(-k) \to 0$$

for $k = 1$ and $k = 2$, and the vanishings

$$\text{Ext}^0(E, \mathcal{O}_{\mathbb{P}^2}(-k)) = \text{Ext}^1(E, \mathcal{O}_{\mathbb{P}^2}(-k)) = 0 \text{ for } k = 1, 2.$$  

The first vanishing is clear. The second follows from the local to global spectral sequence:

$$E_2^{p,q} = H^p(\text{Ext}^q(E, \mathcal{O}_{\mathbb{P}^2}(-k))) \to \text{Ext}^{p+q}(E, \mathcal{O}_{\mathbb{P}^2}(-k))$$

with vanishing $E_2$ terms when $p + q = 1$. This proves the claim about the obstruction theory. Equation (10) still holds by the same methods.

ABSTRACT. The Cauchy problem for the semi-relativistic Schrödinger-Poisson system of equations is studied in $\mathbb{R}^n$, $n \geq 1$, for a wide class of nonlocal interactions. Furthermore, the asymptotic behavior of the solution as the mass tends to infinity is rigorously discussed, and compared with solutions to the non-relativistic Schrödinger-Poisson system.

2010 Mathematics Subject Classification: 82D10, 82C10
Keywords and Phrases: Schrödinger-Poisson system, mean-field dynamics, long-range interaction, functional spaces, density matrices, Cauchy problem, global existence, infinite mass limit.

1 INTRODUCTION

1.1 MOTIVATION AND HEURISTIC DISCUSSION

In this article, we study the global Cauchy problem for the semi-relativistic Schrödinger-Poisson system in $\mathbb{R}^n$, $n \geq 1$, for a wide class of nonlocal interactions, both in the attractive and repulsive cases. This system is relevant to the description of many-body semi-relativistic quantum particles in the mean-field limit. We consider a system of $N$ semi-relativistic quantum particles in $\mathbb{R}^n$, $n \geq 1$ with long-range two-body interactions $g \sum_{1\leq i<j\leq N} \frac{1}{|x_i-x_j|^\gamma}$, with $0 < \gamma \leq 1$ if $n \geq 2$, and $0 < \gamma < 1$ if $n = 1$, and with $g \in \mathbb{R}$. In the mean-field
limit, one can formally show that the density matrix that describes the mixed state of the system satisfies the Hartree-von Neumann equation

\[
\begin{cases}
i \partial_t \rho(t) = [H_m + w(t) \ast n(t), \rho(t)], & x \in \mathbb{R}^n, \ n \geq 1, \ t \geq 0 \\
H_m = \sqrt{m^2 - \Delta} - m, \ w(t) = g \frac{1}{|x|^n}, \ n(t, x) = \rho(t, x, x), \ \rho(0) = \rho_0
\end{cases}
\]

where \( \Delta \) stands for the \( n \)-dimensional Laplacian, \( \ast \) stands for convolution in \( \mathbb{R}^n \), and \( m \geq 0 \) is the mass.\(^1\) Since \( \rho_0 \) is a positive, self-adjoint trace-class operator acting on \( L^2(\mathbb{R}^n) \), its kernel can be decomposed with respect to an orthonormal basis of \( L^2(\mathbb{R}^n) \),

\[
\rho_0(x, y) = \sum_{k \in \mathbb{N}} \lambda_k \psi_k(x) \overline{\psi_k(y)}
\]

where \( \{\psi_k\}_{k \in \mathbb{N}} \) denotes an orthonormal basis of \( L^2(\mathbb{R}^n) \). Furthermore,

\[
\Delta := \{\lambda_k\}_{k \in \mathbb{N}} \in l^1, \ \lambda_k \geq 0, \ \sum_k \lambda_k = 1.
\]

We will show that there exists a one-parameter family of complete orthonormal bases of \( L^2(\mathbb{R}^n) \), \( \{\psi_k(t)\}_{k \in \mathbb{N}} \), for \( t \in \mathbb{R}_+ \), such that the kernel of the solution \( \rho(t) \) to (1.1) can be represented as

\[
\rho(t, x, y) = \sum_{k \in \mathbb{N}} \lambda_k \psi_k(t, x) \overline{\psi_k(t, y)}.
\]

Substituting (1.3) in (1.1), the one-parameter family of orthonormal vectors \( \{\psi_k(t)\}_{k \in \mathbb{N}} \) is seen to satisfy the semi-relativistic Schrödinger-Poisson system

\[
\frac{i}{\partial t} \psi_k = H_m \psi_k + V \psi_k, \ k \in \mathbb{N}
\]

\[
V[\Psi] = w \ast n[\Psi], \ \Psi := \{\psi_k\}_{k=1}^{\infty},
\]

\[
n[\Psi(x, t)] = \sum_{k=1}^{\infty} \lambda_k |\psi_k|^2.
\]

The purpose of this note is to show global well-posedness of (1.4) in a suitable Banach space (to be specified below), and to study the asymptotics of the solution as the mass \( m \) tends to \( \infty \), which we compare to solutions to the non-relativistic Schrödinger-Poisson system, see [11]. The semi-relativistic Schrödinger-Poisson system of equations in a finite domain of \( \mathbb{R}^3 \) and with repulsive Coulomb interactions has been studied recently in [1, 2]. Here, we generalize the result of [1] in several ways. First, the problem is studied in \( \mathbb{R}^n, \ n \geq 1.\)

\(^1\)The rigorous derivation of the semi-relativistic Hartree-von Neumann equation is a topic of future work, see [3, 4] for a derivation of this system of equations in the non-relativistic case.
Semi-relativistic Schrödinger-Poisson system in $\mathbb{R}^n$

Second, we consider a wide class of nonlocal interactions in both the attractive and repulsive cases, and which includes the repulsive Coulomb case in three spatial dimensions. Third, in the infinite mass limit $m \to \infty$, we prove that solutions to the semi-relativistic, and to the non-relativistic Schrödinger-Poisson systems become indistinguishable; the latter has been studied extensively, see for example [5, 8] and references therein. In the special case when the initial density matrix is a pure state $\rho_0 = |\psi_0\rangle\langle\psi_0|$, the Schrödinger-Poisson system becomes a single Hartree equation

$$i\partial_t \psi = (\sqrt{m^2 - \Delta} - m)\psi + (w_\gamma \ast |\psi|^2)\psi, \quad \psi(0) = \psi_0.$$ 

In that sense, our analysis generalizes the results of [10, 7] to the effective dynamics of a mixed state of a semi-relativistic system.

The organization of this paper is as follows. In Subsection 1.3 we state our main results. We prove local and global well-posedness in Section 2. Finally, in Section 3, we discuss the asymptotic behavior of the solutions as the mass tends to infinity. For the benefit of a general reader, we recall some useful results about fractional integration and fractional Leibniz rule in Appendix A.

1.2 Notation

- $A \lessapprox B$ means that there exists a positive constant $C$ independent mass $m$ such that $A \leq C B$.
- $L^p$ stands for the standard Lebesgue space. Furthermore, $L^p B = L^p(I; B)$. $\langle \cdot, \cdot \rangle_{L^2}$ denotes the $L^2(\mathbb{R}^n)$ inner product. We will often use the abbreviated notation $L^p_T$ for $L^p([0,T])$, in the situation where $[0,T]$ denotes a time interval.
- $l^1 = \{ \{ a_l \}_{l \in \mathbb{N}} \mid \sum_{l \geq 1} |a_l| < \infty \}$. 
- $W^{s,p} = (-\Delta + 1)^{-s} L^p$, the standard (complex) Sobolev space. When $p = 2$, $W^{s,2} = H^s$. $H^s$ denotes the homogeneous Sobolev space with norm $\|\psi\|_{H^s} = (\langle \psi, (-\Delta)^s \psi \rangle_{L^2})^{1/2}$.
- For fixed $\lambda \in l^1$, $\lambda_k \geq 0$, and for sequences of functions $\Phi := \{ \phi_k \}_{k \in \mathbb{N}}$ and $\Psi := \{ \psi_k \}_{k \in \mathbb{N}}$, we define the inner product

$$\langle \Phi, \Psi \rangle_{L^2} := \sum_{k \geq 1} \lambda_k \langle \phi_k, \psi_k \rangle_{L^2},$$

which induces the norm

$$\|\Phi\|_{L^2} = \left( \sum_{k \geq 1} \lambda_k \|\phi_k\|_{L^2}^2 \right)^{1/2}.$$ 

The corresponding Hilbert space is $L^2$. 

Documenta Mathematica 18 (2013) 343–357
For fixed $\lambda \in l^1$, $\lambda_k \geq 0$,

$$\mathcal{H}^s = \{ \Psi = \{ \psi_k \}_{k \in \mathbb{N}} \mid \psi_k \in H^s, \sum_{k \geq 1} \lambda_k \| \psi_k \|^2_{H^s} < \infty \}$$

is a Banach space with norm $\| \Psi \|_{\mathcal{H}^s} = (\sum_{k \geq 1} \lambda_k \| \psi_k \|^2_{H^s})^{\frac{1}{2}}$.

For fixed $\lambda \in l^1$, $\lambda_k \geq 0$,

$$\dot{\mathcal{H}}^s = \{ \dot{\Psi} = \{ \dot{\psi}_k \}_{k \in \mathbb{N}} \mid \dot{\psi}_k \in \dot{H}^s, \sum_{k \geq 1} \lambda_k \| \dot{\psi}_k \|^2_{\dot{H}^s} < \infty \}$$

is a Banach space with norm $\| \dot{\Psi} \|_{\dot{\mathcal{H}}^s} = (\sum_{k \geq 1} \lambda_k \| \dot{\psi}_k \|^2_{\dot{H}^s})^{\frac{1}{2}}$.

1.3 Statement of main results

For $s > 0$, we define the state space for the Schrödinger-Poisson system by

$$S^s := \{(\Psi, \Delta) \mid \Psi = \{ \psi_k \}_{k=1}^{\infty} \text{ is a complete orthonormal system in } L^2(\mathbb{R}^n), \Delta = \{ \lambda_k \}_{k \in \mathbb{N}} \in l^1, \lambda_k \geq 0 \}.$$ 

The following is our first main result about the global Cauchy problem.

**Theorem 1.1.** Consider the system of equations (1.4)-(1.6), with $m \geq 0$, with $0 < \gamma \leq 1$ if $n \geq 2$, and $0 < \gamma < 1$ if $n = 1$. Suppose that $(\Psi(0), \Delta) \in S^s$, $s \geq 1/2$. If $g \geq 0$, or $g < 0$ with $\| \Psi(0) \|_{L^2}$ small enough, then there is a unique mild solution $(\Psi, \Delta) \in C([0, \infty), S^s)$.

**Remark 1.2.** $\Delta$ is time-independent, and hence the evolution can be thought as that of $\Psi \in \mathcal{H}^s$.

**Remark 1.3.** Local well-posedness requires less regularity, in particular, $s \geq \gamma/2$, see Proposition 2.2 in Section 2.1. On the other hand, in order to enhance local to global well-posedness, energy conservation is used, and consequently, $s \geq \frac{1}{2}$ is assumed to ensure finiteness of the energy.

**Remark 1.4.** It follows from the proof of local well-posedness (Proposition 2.2 in Section 2.1) that there exists a positive time $T$ independent of $m \geq 0$ such that $\| \Psi \|_{L^\infty_T \mathcal{H}^s} \leq C \| \Psi(0) \|_{\mathcal{H}^s}$, $s \geq \gamma/2$, where $C > 0$ is independent of $m$.

**Remark 1.5.** The solution is continuous in the mass $m$. In particular, as $m \searrow 0$, and for $T > 0$ fixed, $\Psi \rightarrow \Psi(0)$ strongly in $L^\infty_T(\mathcal{H}^s)$, $s \geq 1/2$, where $\Psi(0)$ satisfies (1.4)-(1.6) with $m = 0$ and initial condition $\Psi(0)$, see Proposition 2.6 in Sect. 2.
The second result is about the infinite mass limit. Let $\Gamma$ satisfy the nonrelativistic Schrödinger-Poisson system of equations

$$i\frac{\partial \psi_k}{\partial t} = -\frac{1}{2m} \Delta \psi_k + V(\psi_k), \quad k \in \mathbb{N}$$

$$V[\Psi] = w_\gamma * n[\Psi], \quad \Psi := \{\psi_k\}_{k=1}^\infty, \quad n[\Psi(x, t)] = \sum_{k=1}^\infty \lambda_k |\psi_k|^2,$$

with initial condition $\Psi(0) = \{\psi_k(0)\}_{k \in \mathbb{N}}$.

**Theorem 1.6.** Suppose that the hypotheses of Theorem 1.1 hold. Then there exists $\tau > 0$ such that $\Psi - \Gamma \to 0$ in $L^\infty(\mathcal{H}^s)$, $s \geq \gamma/2$, as $m \to \infty$.

In other words, when the mass tends to infinity, the solutions of the semi-relativistic, and of the non-relativistic Schrödinger-Poisson systems of equations asymptotically become indistinguishable.

**Remark 1.7.** The proof of Theorem 1.6 relies on local well-posedness, and this is why the result holds for $s \geq \gamma/2$.

2 **Well-posedness**

2.1 **Local well-posedness**

In what follows, we fix $\lambda \in L^1$, $\lambda_i \geq 0$, $i \in \mathbb{N}$. We start by showing that the nonlinearity $V[\Psi] \Psi$ is locally Lipschitz.

**Lemma 2.1.** For $\Psi, \Phi \in \mathcal{H}^s$, $s \geq \gamma/2$,

$$\|V[\Psi] \Psi - V[\Phi] \Phi\|_{\mathcal{H}^s} \lesssim (\|\Psi\|_{\mathcal{H}^s}^2 + \|\Phi\|_{\mathcal{H}^s}^2) \|\Psi - \Phi\|_{\mathcal{H}^s}.$$ 

**Proof.** The proof relies on the fractional Leibniz rule and fractional integration, see Appendix A. From the Minkowski inequality,

$$\|V[\Psi] \Psi - V[\Phi] \Phi\|_{\mathcal{H}^s} \lesssim (\|V[\Psi] - V[\Phi]\|_{\mathcal{H}^s} + \|\Psi - \Phi\|_{\mathcal{H}^s}).$$  

(2.1)

We begin by estimating the first term on the right.

$$\|V[\Psi] - V[\Phi]\|_{\mathcal{H}^s} \lesssim \sum_{k,l \geq 1} \lambda_k \lambda_l \|w_\gamma * (|\psi_l|^2 - |\phi_l|^2) \psi_k\|_{\mathcal{H}^s}$$

$$\lesssim \sum_{k,l \geq 1} \lambda_k \lambda_l \left(\|w_\gamma * (|\psi_l|^2 - |\phi_l|^2)\|_{L^\infty} \|\psi_k\|_{\mathcal{H}^s}\right.$$  

$$\left.\quad + \|w_\gamma * (|\psi_l|^2 - |\phi_l|^2)\|_{L^\infty} \|\psi_k\|_{\mathcal{H}^s}\right)$$

$$\lesssim \sum_{k,l \geq 1} \lambda_k \lambda_l \left(\|\psi_l - \phi_l\|_{\mathcal{H}^{s/2}} (\|\psi_l\|_{\mathcal{H}^{s/2}} + \|\psi_l\|_{\mathcal{H}^{s/2}}) \|\psi_k\|_{\mathcal{H}^s}\right.$$  

$$\left.\quad + \|\psi_l\|_{L^{2\gamma/\gamma - 1}} \|\psi_k\|_{\mathcal{H}^{s/2}}\right)$$

$$\lesssim (\|\Psi\|_{\mathcal{H}^s}^2 + \|\Phi\|_{\mathcal{H}^s}^2) \|\Psi - \Phi\|_{\mathcal{H}^s}. \quad (2.2)$$
Given \( H \) and \( \gamma > 0 \) such that the unique solution to the Schrödinger-Poisson system of equations is locally well-posed. Using a standard contraction map argument, the generalized semi-relativistic Schrödinger-Poisson system of equations is locally well-posed.

**Proposition 2.2.** Consider the system of equations (1.4)-(1.6), with \( m \geq 0 \), \( 0 < \gamma \leq 1 \) if \( n \geq 2 \), and \( 0 < \gamma < 1 \) if \( n = 1 \). Suppose that \( (\Psi(0), \Lambda) \in \mathbb{S}^s, s \geq \gamma/2 \). Then there exists a positive time \( T \) such that the unique solution \( \Psi \in C([0, T]; \mathcal{H}^s) \). Furthermore, there exists a maximal time \( \tau^* \in (0, \infty) \) such that \( \lim_{t \to \tau^*} \|\Psi(t)\|_{\mathcal{H}^s} = \infty \).

**Proof.** Given \( \rho, T > 0 \), consider the Banach space

\[
\mathcal{B}^s_{\rho} = \{ \Psi \in L^\infty_{\mathcal{F}}(\mathcal{H}^s) : \|\Psi\|_{L^\infty_{\mathcal{F}} \mathcal{H}^s} \leq \rho \}.
\]

Let \( U^{(m)} = e^{-itH_m} \), the unitary operator generated by the semi-relativistic Hamiltonian \( H_m = \sqrt{-\Delta + m^2} - m \). We define the mapping \( \mathcal{N} \) by

\[
\mathcal{N}(\Psi)(t) = U^{(m)}(t)\Psi(0) - i \int_0^t U^{(m)}(t - t')V[\Psi(t')][\Psi(t')]dt',
\]

which is the solution given by the Duhamel formula. First we show that \( \mathcal{N} \) is a mapping from \( \mathcal{B}^s_{\rho} \) into itself.

\[
\|\mathcal{N}(\Psi)\|_{L^\infty_{\mathcal{F}} \mathcal{H}^s} \leq \|\Psi(0)\|_{\mathcal{H}^s} + T \|V[\Psi]\|_{L^\infty_{\mathcal{F}} \mathcal{H}^s},
\]

\[
\leq \|\Psi(0)\|_{\mathcal{H}^s} + T \sum_{k,l \geq 1} \lambda_k \lambda_l \|w_{\gamma} \ast |\psi|^2\|_{L^\infty_{\mathcal{F}} \mathcal{H}^s},
\]

\[
\leq \|\Psi(0)\|_{\mathcal{H}^s} + T \sum_{k,l \geq 1} \lambda_k \lambda_l \{\|w_{\gamma} \ast (|\psi|^2)\|_{L^\infty_{\mathcal{F}} \mathcal{H}^s} + \|w_{\gamma} \ast (|\psi|^2)\|_{L^\infty_{\mathcal{F}} W^s_{-\frac{1}{2}} \mathcal{H}^s}\},
\]

where we have used fractional Leibniz rule (Lemma A.1) in the last inequality. It follows from fractional integration (Lemma A.2) and Sobolev embedding...
H^{\frac{\gamma}{2}} \hookrightarrow L^{2+\gamma}_{\mathbb{R}^n} \) that

\| \mathcal{N}(\Psi) \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \leq \| \Psi(0) \|_{H^{\frac{\gamma}{2}}} + T \sum_{k, l \geq 1} \lambda_k \lambda_l \{ \| \psi_l \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \| \psi_k \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \}

\leq \| \Psi(0) \|_{H^{\frac{\gamma}{2}}} + T \sum_{k, l \geq 1} \lambda_k \lambda_l \left\{ \| \psi_l \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \| \psi_k \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \right\}^2

\leq \| \Psi(0) \|_{H^{\frac{\gamma}{2}}} + \| \Psi \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \| \Psi \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}}.

where we have used the fact that \( \lambda_k \geq 1 \) and \( \sum_{k \geq 1} \lambda_k = 1 \) before the last inequality.

Since \( s \geq \frac{\gamma}{2} \), and since by assumption, \( \Psi \in B^s_{T, \rho} \), we can choose \( T \) and \( \rho \) such that

\| \Psi(0) \|_{H^{\frac{\gamma}{2}}} \leq \frac{\rho}{2}, \quad T \rho^2 < \frac{1}{2},

it follows from the last inequality and the Duhamel formula that

\| \Psi \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \leq 2 \| \Psi(0) \|_{H^{\frac{\gamma}{2}}} \leq \rho.

Second, since the nonlinearity is locally Lipschitz (Lemma 2.1), \( \mathcal{N} \) is a contraction map for sufficiently small \( T \).

\| \mathcal{N}(\Psi) - \mathcal{N}(\Phi) \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}} \leq T \| V[\Psi] \Psi - V[\Phi] \Phi \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}}

\leq T \rho^2 \| \Psi - \Phi \|_{L^{2+\gamma}_{\mathbb{R}^n} H^{\frac{\gamma}{2}}}.

Local well-posedness follows from a standard contraction mapping argument, see for example, [6].

It follows from local well-posedness that for every \( k \in \mathbb{N} \), \( \| \psi_k \|_{L^2} \) is conserved.

**Lemma 2.3.** Suppose that the hypotheses of Proposition 2.2 hold. Then

\| \psi_k(t) \|_{L^2} = \| \psi_k(0) \|_{L^2}, \quad t \in [0, \tau^*).

**Proof.** Multiplying (1.4) by \( \bar{\psi}_k \) and integrating over space yields

\[ \frac{i}{2} \partial_t \| \psi_k \|^2 = \langle \psi_1, H_m \psi_k \rangle + \langle \psi_1, V[\Psi] \psi_k \rangle. \]

Taking the imaginary part of both sides of the equation yields \( \partial_t \| \psi_k \|^2 = 0 \).

The energy functional associated with the semi-relativistic Schrödinger-Poisson system is

\[ \mathcal{E}(\Psi) = \frac{1}{2} \langle \Psi, H_m \Psi \rangle_{L^2} + \frac{1}{4} \langle \Psi, V[\Psi] \Psi \rangle_{L^2}. \]

Formally, conservation of energy follows from multiplying (1.4) by \( \lambda_k \partial_k \bar{\psi}_k \), integrating over space, and summing over \( k \geq 1 \). To make the argument precise, we need a regularization procedure.
Lemma 2.4. Suppose that the hypotheses of Proposition 2.2 hold. Then $E(\Psi(t)) = E(\Psi(0))$, $t \in [0, \tau^*)$, is satisfied for solutions $\Psi \in C([0, \tau^*), H^s)$ with $s \geq \frac{1}{2}$.

Proof. Let $J_\varepsilon = (\varepsilon H_m + 1)^{-1}$, $\varepsilon > 0$, act on the sequence of embedding spaces

$$
\cdots \ H^{\frac{s}{2}} \hookrightarrow H^{\frac{1}{2}} \hookrightarrow H^{-\frac{1}{2}} \hookrightarrow H^{-\frac{3}{2}} \cdots
$$

It follows from fractional calculus that

(i) $J_\varepsilon$ is a bounded operator from $H^s$ to $H^{s+1}$,

(ii) $\|J_\varepsilon \Psi\|_{H^s} \leq \|\Psi\|_{H^s}$, and

(iii) $J_\varepsilon \Psi \rightarrow \Psi$ strongly in $H^s$ as $\varepsilon \rightarrow 0$.

Now,

$$
E(J_\varepsilon \Psi(t_2)) - E(J_\varepsilon \Psi(t_1)) = \int_{t_1}^{t_2} \partial_t E(J_\varepsilon \Psi(t)) \, dt
$$

$$
= \operatorname{Re}\left\{ \int_{t_1}^{t_2} -i \langle H_m J_\varepsilon \Psi(t), H_m J_\varepsilon \Psi(t) \rangle_{L^2} + \langle J_\varepsilon V[J_\varepsilon \Psi(t)], J_\varepsilon \Psi(t) \rangle_{L^2} + \langle J_\varepsilon V[J_\varepsilon \Psi(t)], J_\varepsilon V[J_\varepsilon \Psi(t)] \Psi(t) \rangle_{L^2} \right\}.
$$

The first term is trivially zero, since $H_m J_\varepsilon = J_\varepsilon H_m$. Let

$$
g_\varepsilon(t) = \operatorname{Re}\left\{ \langle H_m J_\varepsilon \Psi(t), J_\varepsilon V[J_\varepsilon \Psi(t)] \Psi(t) \rangle_{L^2} + \langle J_\varepsilon V[J_\varepsilon \Psi(t)], J_\varepsilon \Psi(t) \rangle_{L^2} + \langle J_\varepsilon V[J_\varepsilon \Psi(t)], J_\varepsilon V[J_\varepsilon \Psi(t)] \Psi(t) \rangle_{L^2} \right\}.
$$

Then

$$
E(J_\varepsilon \Psi(t_2)) - E(J_\varepsilon \Psi(t_1)) = \int_{t_1}^{t_2} g_\varepsilon(t) \, dt.
$$

It follows from the above properties (i)-(iii) of $J_\varepsilon$ that $\lim_{\varepsilon \rightarrow 0} g_\varepsilon(t) = 0$. Furthermore,

$$
g_\varepsilon(t) \leq \|V[\Psi(t)]\Psi(t)\|_{L^2} \|H_m \Psi(t)\|_{L^2} + \|V[\Psi(t)]\Psi(t)\|^2_{L^2}. \quad (2.4)
$$

Using Lemma A.3, we have

$$
\|V[\Psi]\|_{L^2} \lesssim \sum_{k,l \geq 1} \lambda_k \lambda_l \|\psi_l\|^2_{H^\frac{1}{2}} \|\psi_k\|_{L^2}.
$$
The Gagliardo-Nirenberg inequality,
\[ \| \psi_l \|_{H^{2\gamma}} \lesssim \| \psi_l \|_{H^2} \| \psi_l \|_{L^2}^{1-\gamma}, \]
together with conservation of charge (Lemma 2.3), yields
\[ \| V[\Psi] \|_{L^2} \lesssim \sum_{l \geq 1} \lambda_l \| \psi_l \|_{H^{2\gamma}}^2 \]
\[ \lesssim \left( \sum_{l \geq 1} \lambda_l \| \psi_l \|_{H^{2\gamma}}^2 \right)^\gamma \]
\[ \lesssim \| \Psi \|_{H^2}^\gamma, \]
where we have used in the second inequality the fact that \[ \sum_{l \geq 1} \lambda_l = 1, \quad \lambda_l \geq 0, \]
and \( f(x) = x^\gamma, \quad 0 < \gamma < 1, \) is concave (equality when \( \gamma = 1 \) is trivially satisfied). Substituting back in (2.4) yields
\[ g_\varepsilon(t) \lesssim \| \Psi \|_{H^{2\gamma}}^{\gamma+1} + \| \Psi \|_{H^{2\gamma}} \]
which is finite for \( t < \tau^* \). By the Dominated Convergence Theorem,
\[ \mathcal{E}(\Psi(t_2)) - \mathcal{E}(\Psi(t_1)) = \int_{t_1}^{t_2} \lim_{\varepsilon \to 0} g_\varepsilon(t) \, dt = 0, \]
as claimed.

Global well-posedness in \( H^s \), for \( s \geq \frac{1}{2} \), follows from conservation of charge and energy.

Proposition 2.5. Suppose that the hypotheses of Proposition 2.2 hold. Then, if \( g > 0 \) or \( g < 0 \) with \( \| \Psi(0) \|_{L^2} \) small enough, and for \( s \geq \frac{1}{2} \),
\[ \| \Psi(t) \|_{H^s} \leq C \| \Psi(0) \|_{H^s} e^{C(t E(\Psi(0)))^{\alpha} + \| \Psi(0) \|_{L^2}^\delta t}, \]
where \( C, \alpha \) and \( \delta \) are positive constants that are independent of \( m \geq 0 \).

Proof. We start by bounding \( \| \Psi(t) \|_{H^s} \) from above, uniformly in time.
\[ \langle \Psi, V[\Psi] \Psi \rangle_{L^2} = \sum_{l \geq 1} \lambda_l \langle \psi_l, V[\Psi] \psi_l \rangle \]
\[ \leq \| V[\Psi] \|_{L^\infty} \| \Psi \|_{L^2}^2 \]
\[ \lesssim \left( \sum_{k \geq 1} \lambda_k \| \psi_k \|_{H^{2\gamma}}^2 \right) \| \Psi \|_{L^2}^2 \]
\[ \lesssim \left( \sum_{k \geq 1} \lambda_k \| \psi_k \|_{H^{2\gamma}}^{2\gamma} \right) \| \Psi \|_{L^2}^2 \]
\[ \leq \left( \sum_{k \geq 1} \lambda_k \| \psi_k \|_{H^{2\gamma}}^{2\gamma} \right)^\gamma \| \Psi \|_{L^2}^2 \]
\[ \lesssim \| \Psi \|_{H^2}^\gamma \| \Psi \|_{L^2}^2. \]
Here, we used Hölder’s inequality in the second line, Lemma A.3 in the third line, the Gagliardo-Nirenberg inequality and conservation of charge in the fourth line, and $\sum_{k \geq 1} \lambda_k = 1$, $\lambda_k \geq 0$, the fact that $x^\gamma$, $0 < \gamma < 1$, is concave in the fifth line (equality when $\gamma = 1$ is trivially satisfied). Together with conservation of energy (Lemma 2.4), this implies that for $g > 0$ or $g < 0$ with $\|\Psi(0)\|_{L^2}$ small enough,

$$\|\Psi\|_{H^s} \leq \alpha (\mathcal{E}(\Psi(t)) + \|\Psi(0)\|_{L^2}^2), \tag{2.5}$$

where $\alpha$ and $\delta$ are constants independent of the mass $m \geq 0$. Now, it follows from the Duhamel formula that

$$\|\Psi(t)\|_{H^s} \leq \|\Psi(0)\|_{H^s} + \int_0^t \|\Psi(t')\|_{H^s}^2 \|\Psi(t')\|_{H^s} dt' \leq \|\Psi(0)\|_{H^s} + \alpha (\mathcal{E}(\Psi(t)) + \|\Psi(0)\|_{L^2}^4) \int_0^t \|\Psi(t')\|_{H^s} dt',$n

where we used Hölder’s and Minkowski inequalities in the first line, and (2.5) in the second line. By Gronwall’s lemma,

$$\|\Psi(t)\|_{H^s} \leq \|\Psi(0)\|_{H^s} e^{\alpha (\mathcal{E}(\Psi(0)) + \|\Psi(0)\|_{L^2}^4)t}$$

follows.

**Proof of Theorem 1.1.** It follows from Propositions 2.2 and 2.5 that $\tau^* = \infty$, i.e., the generalized semi-relativistic Schrödinger-Poisson system of equations is globally well-posed.

We now prove the claim of Remark 1.5 about the asymptotic behaviour of the system as the mass tends to zero.

**PROPOSITION 2.6.** Consider the system of equations (1.4)-(1.6) with initial condition $(\Delta \Psi(0))$. Let $\Psi^{(0)}$ denote the solution of the initial value problem with mass $m = 0$, and fix $T > 0$. Under the hypotheses of Proposition 2.5, $\Psi \to \Psi^{(0)}$ strongly in $L^\infty_T (H^s)$, $s \geq 1/2$, as $m \to 0$.

**Proof.** Proposition 2.5 implies that, given $T > 0$, there exists finite $\rho > 0$ such that

$$\sup_{m \in [0,1]} \|\Psi\|_{L^\infty_T H^s} < \rho. \tag{2.6}$$

We now compare the norm of the difference of $\Psi(t)$ and $\Psi^{(0)}(t)$, $t \in [0, T]$. It
follows from the Duhamel formula that
\[
\|\Psi(t) - \Psi^{(0)}(t)\|_{H^s} \lesssim \| \left( U^{(m)}(t) - U^{(0)}(t) \right) \Psi(0) \|_{H^s} + \int_0^t \| V[\Psi(t')]\Psi(t') - V[\Psi^{(0)}(t')]\Psi^{(0)}(t') \|_{H^s} \ dt' + \| \left( U^{(m)}(t') - U^{(0)}(t') \right) V[\Psi^{(0)}(t')]\Psi^{(0)}(t') \|_{H^s} \ dt' \\
\lesssim mT\|\Psi(0)\|_{H^s} + \int_0^t \| V[\Psi(t')]\Psi(t') - V[\Psi^{(0)}(t')]\Psi^{(0)}(t') \|_{H^s} \ dt' + \frac{mT^2}{2}\| V[\Psi^{(0)}]\Psi^{(0)} \|_{L^\infty H^s},
\]
where we used Minkowski inequality in the first inequality and Hölder’s inequality in the second. We also used \( \sqrt{-\Delta + m^2 - m} \leq m \).

It follows from the fact that the nonlinearity is locally Lipschitz (Lemma 2.1) and (2.6) that
\[
\| V[\Psi(t')]\Psi(t') - V[\Psi^{(0)}(t')]\Psi^{(0)}(t') \|_{H^s} \lesssim \rho^2\|\Psi(t') - \Psi^{(0)}(t')\|_{H^s},
\]
\[
\| V[\Psi^{(0)}]\Psi^{(0)} \|_{L^\infty H^s} \lesssim \rho^3.
\]
Hence
\[
\|\Psi(t) - \Psi^{(0)}(t)\|_{H^s} \lesssim m\rho T + m\rho^3 T + \rho^2 \int_0^t \|\Psi(t') - \Psi^{(0)}(t')\|_{H^s} \ dt'.
\]
By Gronwall’s lemma, \( \Psi \to \Psi^{(0)} \) strongly in \( L^\infty(\mathcal{H}^s) \) as \( m \to 0 \).*

3 Asymptotic behaviour of solutions as mass tends to infinity

In this section, we discuss the asymptotics of the solution as the mass \( m \) tends to infinity.

Proof of Theorem 1.6. Recall that from the proof of local well-posedness in Section 2.1, there exists \( T > 0 \) independent of \( m \) such that \( \|\Psi\|_{L^\infty_T H^s} \leq C\|\Psi(0)\|_{H^s}, \ s \geq \gamma/2, \) where \( C \) is independent of \( m \). Similarly, one can show that there exists \( T' > 0 \) independent of \( m \) such that \( \|\Gamma\|_{L^\infty_T H^r} \leq C\|\Psi(0)\|_{H^r}, \) where \( C \) is independent of \( m \). Let \( \tau = \min( T, T' ) \). Let \( \tilde{\Gamma} = \{ \tilde{\gamma}_k \}_{k \in \mathbb{N}} \) satisfy the system of equations
\[
\begin{cases}
 i\partial_t \tilde{\Gamma} = V[\tilde{\Gamma}]\tilde{\Gamma}, \\
 V[\tilde{\Gamma}] = w_\gamma \ast n[\tilde{\Gamma}], \\
 n[\tilde{\Gamma}] = \sum_{k=1}^\infty \lambda_k |\tilde{\gamma}_k|^2,
\end{cases}
\]
with initial condition \( \tilde{\Gamma}(0) = \Psi(0) \). Alternatively, \( \tilde{\Gamma} \) satisfies the integral equation
\[
\tilde{\Gamma}(t) = \Psi(0) - i \int_0^t V[\tilde{\Gamma}(t')]\tilde{\Gamma}(t') \ dt'.
\]
Uniqueness of the solution follows from the fact that the nonlinearity is locally Lipschitz (Lemma 2.1). We are going to compare Ψ to $\tilde{\Gamma}$, and then $\tilde{\Gamma}$ to $\Gamma$.

\[
\|\Psi(t) - \tilde{\Gamma}(t)\|_{\mathcal{H}^s} \leq \| \left( U^{(m)}(t) - 1 \right) \Psi(0) \|_{\mathcal{H}^s} + \int_0^t \| \left( U^{(m)}(t-t') - 1 \right) V[\tilde{\Gamma}(t')]\tilde{\Gamma}(t') \|_{\mathcal{H}^s} dt' + \int_0^t \| V[\Psi(t')]\Psi(t') - V[\tilde{\Gamma}(t')]\tilde{\Gamma}(t') \|_{\mathcal{H}^s} dt'.
\]

(3.1)

To estimate the first term on the right-hand-side, we apply the Fourier transform and use Parseval’s Theorem,

\[
\| \left( U^{(m)}(t) - 1 \right) \Psi(0) \|_{\mathcal{H}^s}^2 = \sum_{l \geq 1} \lambda_l \int_{\mathbb{R}^d} |e^{-it(\sqrt{m^2 + |k|^2} - m)} - 1|^2 (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk \leq \sum_{l \geq 1} \lambda_l \int_{|k| \leq m^+} |e^{-it(\sqrt{m^2 + |k|^2} - m)} - 1|^2 (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk + \int_{|k| > m^+} |e^{-it(\sqrt{m^2 + |k|^2} - m)} - 1|^2 (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk \leq \sum_{l \geq 1} \lambda_l \int_{|k| \leq m^+} \frac{l^2 |k|^4}{(\sqrt{m^2 + |k|^2} + m)^2} (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk + 4 \int_{|k| > m^+} (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk \leq \frac{\nu^2}{4m} \| \Psi(0) \|_{\mathcal{H}^s}^2 + 4 \sum_{l \geq 1} \int_{|k| > m^+} (1 + |k|^2) |\hat{\psi}(0, k)|^2 dk \to 0 \text{ as } m \to \infty.
\]

Since $V[\tilde{\Gamma}]\tilde{\Gamma} \in \mathcal{H}^s$, it follows from the Dominated Convergence Theorem that

\[
\lim_{m \to \infty} \int_0^t \| \left( U^{(m)}(t-t') - 1 \right) V[\tilde{\Gamma}(t')]\tilde{\Gamma}(t') \|_{\mathcal{H}^s} dt' = 0.
\]

To estimate the third term, let $\rho > 0$ be a constant such that

\[
\sup_{m \geq 1} (\| \Psi \|_{L^\infty_{\mathcal{H}^s}} + \| \Gamma \|_{L^\infty_{\mathcal{H}^s}}) + \| \tilde{\Gamma} \|_{L^\infty_{\mathcal{H}^s}} \leq \rho.
\]

It follows from the fact that the nonlinearity is locally Lipschitz that

\[
\| V[\Psi(t')]\Psi(t') - V[\tilde{\Gamma}(t')]\tilde{\Gamma}(t') \|_{\mathcal{H}^s} \leq C \rho^2 \| \Psi(t') - \tilde{\Gamma}(t') \|_{\mathcal{H}^s},
\]

where $C$ is a positive constant independent of $m$. 

Documenta Mathematica 18 (2013) 343–357
Therefore,

$$\|\Psi(t) - \tilde{\Gamma}(t)\|_{\mathcal{H}} \leq f_m + C\rho^2 \int_0^t \|\Psi(t') - \tilde{\Gamma}(t')\|_{\mathcal{H}} dt',$$

where $f_m$ bounds the first two terms on the r.h.s. of (3.1). As shown above, $\lim_{m \to \infty} f_m = 0$ and $C$ is independent of $m$, so that application of Gronwall’s lemma yields

$$\lim_{m \to \infty} \|\Psi - \tilde{\Gamma}\|_{L^\infty \mathcal{H}} = 0.$$

Similarly, one can show that

$$\|\Gamma(t) - \tilde{\Gamma}(t)\|_{\mathcal{H}} \leq g_m + C\rho^2 \int_0^t \|\Psi(t') - \tilde{\Gamma}(t')\|_{\mathcal{H}} dt',$$

where $\lim_{m \to \infty} g_m = 0$ and $C$ is independent of $m$, and it follows that

$$\lim_{m \to \infty} \|\Gamma - \tilde{\Gamma}\|_{L^\infty \mathcal{H}} = 0.$$

Since

$$\|\Psi - \Gamma\|_{L^\infty \mathcal{H}} \leq \|\Psi - \tilde{\Gamma}\|_{L^\infty \mathcal{H}} + \|\Gamma - \tilde{\Gamma}\|_{L^\infty \mathcal{H}},$$

it follows that

$$\lim_{m \to \infty} \|\Psi - \Gamma\|_{L^\infty \mathcal{H}} = 0,$$

as desired. \(\square\)

**A Appendix**

The following result about the fractional Leibniz rule can be found in [9].

**Lemma A.1.**

$$\|\mathcal{D}^s(uv)\|_{L^p} \lesssim \|\mathcal{D}^s u\|_{L^{q_i}} \|v\|_{L^{r_1}} + \|u\|_{L^{q_i}} \|\mathcal{D}^s v\|_{L^{r_2}},$$

where $\frac{1}{p} = \frac{1}{q_i} + \frac{1}{r_i}$, $i = 1, 2$.

The second result is about inequality involving fractional integral operators, which can be found, for example, in [12].
Lemma A.2. Let $I_\alpha$, for $0 < \alpha < n$, be the fractional integral operator

$$I_\alpha(u) = \int_{\mathbb{R}^n} |x - y|^{\alpha - n} u(y) \, dy.$$ 

Then

$$\|I_\alpha(u)\|_{L^p} \lesssim \|u\|_{L^q}, \quad \frac{1}{p} = \frac{1}{q} - \frac{\alpha}{n}.$$ 

We also recall the following useful Hardy-type inequality.

Lemma A.3. Let $0 < \gamma < n$. Then,

$$\sup_{x \in \mathbb{R}^n} \left| \int_{\mathbb{R}^n} \frac{1}{|x - y|^{\gamma}} |u(y)|^2 \, dy \right| \lesssim \|u\|^2_{H^\gamma}.$$

REALIZABILITY AND ADMISSIBILITY
UNDER EXTENSION OF $p$-ADIC AND NUMBER FIELDS

DANNY NEFTIN AND UZI VISHNE

Received: July 12, 2012
Communicated by Max Karoubi

Abstract. A finite group $G$ is $K$-admissible if there is a $G$-crossed product $K$-division algebra. In this manuscript we study the behavior of admissibility under extensions of number fields $M/K$. We show that in many cases, including Sylow metacyclic and nilpotent groups whose order is prime to the number of roots of unity in $M$, a $K$-admissible group $G$ is $M$-admissible if and only if $G$ satisfies the easily verifiable Liedahl condition over $M$.

2010 Mathematics Subject Classification: 16K20, 12F12
Keywords and Phrases: admissible group; adequate field; tame admissibility; Liedahl’s condition.

1. Introduction

Let $K$ be a field. A field $L \supseteq K$ is called $K$-adequate if it is contained as a maximal subfield in a finite dimensional central $K$-division algebra. A group $G$ is $K$-admissible if there is a $G$-extension $L/K$, i.e. $L/K$ is a Galois extension with $\text{Gal}(L/K) \cong G$, so that $L$ is $K$-adequate. Equivalently, $G$ is $K$-admissible if there is a $G$-crossed product $K$-division algebra. Ever since adequacy and admissibility were introduced in [19], they were studied extensively over various types of fields, especially over number fields.

As oppose to realizability of groups as Galois groups, there are known restrictions on the number fields $K$ over which a given group is $K$-admissible. Liedahl’s condition (which was shown by Schacher [19] over $\mathbb{Q}$, and generalized by Liedahl [9, Theorem 28]) describes such a restriction. We say that $G$ satisfies Liedahl’s condition over $K$, if for every prime $p$ dividing $|G|$, one of the following holds:

(i) $p$ decomposes in $K$ (has at least two prime divisors),
(ii) $p$ does not decompose in $K$, and a $p$-Sylow subgroup $G(p)$ of $G$ is metacyclic and admits a Liedahl presentation over $K$ (for details see Definition 2.4 which is based on [9]).

1The second named author is partially supported by a BSF US-Israel grant 2010/149.
In [19, Theorem 9.1], Schacher showed that any finite group $G$ is admissible over some number field $K$. However, for many groups $G$ it is an open problem to determine the number fields over which they are admissible. In fact, searching for an explicit description for all groups seems hopeless.

In this paper we fix a field $K$ over which $G$ is admissible and ask over which finite extensions of $K$, $G$ is still admissible. We assume our group $G$ is realizable over $M$ and furthermore can be realized over $M$ with prescribed local conditions, i.e. it admits the Grunwald-Neukirch (GN) property. This question then leads (see Section 5.1) via Schacher’s criterion (Theorem 2.1) to the following local realization problem:

**Problem 1.1.** Let $m/k$ be an extension of $p$-adic fields and $G$ a group that is realizable over $k$. Is there a subgroup $H$ of $G$ which is realizable over $m$ and contains a $p$-Sylow subgroup of $G$?

At first we consider the case of $p$-groups, where the problem is whether a $p$-group that is realizable over $k$, is realizable over an extension $m$ of $k$. For $p$ odd, we notice that the maximal pro-$p$ quotient $G_k(p)$ of the absolute Galois group $G_k$ is covered by $G_m(p)$, providing a positive answer:

**Proposition 1.2.** Let $m/k$ be a finite extension of $p$-adic fields where $p$ is an odd prime. Then any $p$-group that is realizable over $k$ is also realizable over $m$.

The simplest behavior one can hope for in terms of admissibility, is that a $K$-admissible group $G$ would be $M$-admissible if and only if it satisfies Liedahl’s condition over $M$. This is indeed the case for various classes of groups:

1. When all Sylow subgroups of $G$ are cyclic [19, Theorem 2.8];
2. When $G$ is abelian and does not fall into a special case over $M$ [2];
3. For metacyclic groups [9],[10];
4. For $G = \text{SL}_2(5)$ [5];
5. For $G = A_6$ or $G = A_7$ [20];
6. For $G = \text{PGL}_2(7)$ [1], and
7. For the Symmetric groups $G = S_n$, $1 \leq n \leq 17$, $n \neq 12, 13$ (by [4], [9] and [19]).

Using Proposition 1.2, we are able to add all the odd-order $p$-groups having the GN-property over $M$ to this list:

**Proposition 1.3.** Let $M/K$ be an extension of number fields and $p$ an odd prime. Let $G$ be a $p$-group that is $K$-admissible and has the GN-property over $M$. Then $G$ is $M$-admissible if and only if $G$ satisfies Liedahl’s condition over $M$.

Propositions 1.2 and 1.3 are proved in Subsection 3.1. We note (in Section 3) that Proposition 1.3 extends to nilpotent groups of odd order and (by Remark 5.1) to Sylow metacyclic groups (having metacyclic Sylow subgroups). However, the following example shows that Problem 1.1 can have a negative answer for some 2-groups:

**Documenta Mathematica 18 (2013) 359–382**
Example 1.4. There is a group $G$, of order $2^6$, which is realizable over $\mathbb{Q}_2$ but not over $\mathbb{Q}_2(\sqrt{-1})$.

For a proof, see Corollary 3.6. In Proposition 3.8 we interpret this example globally:

Example 1.5. There is a rational prime $q$ for which the group $G$ of Example 1.4 is $\mathbb{Q}(\sqrt{q})$-admissible, satisfies Liedahl’s condition over $\mathbb{Q}(\sqrt{-1}, \sqrt{q})$ but is not $\mathbb{Q}(\sqrt{-1}, \sqrt{q})$-admissible.

Liedahl showed that a similar phenomena happens for the groups $S_n$, $n = 12, 13$ and the local extension $\mathbb{Q}_2(\sqrt{-3})/\mathbb{Q}_2$ (see [4]). We shall restrict our discussion to groups which are either of odd order, or with metacyclic 2-Sylow subgroups. For some $p$-adic extensions $m/k$, for $p$ odd, including extensions in which the inertia degree $f(m/k)$ is a $p$-power and $[m:k] > 5$ we show that $G_m$ covers the maximal quotient of $G_k$ with a normal $p$-Sylow subgroup.

We use this method to answer Problem 1.1 positively for odd primes, under the following assumptions. The list of ‘sensitive’ extensions of $p$-adic fields, (16 with $p = 3$ and one for $p = 5$) is described in Subsection 4.2.

Theorem 1.6. Let $p$ be an odd prime. Let $m/k$ be a non-sensitive extension of $p$-adic fields and $G$ a group with a normal $p$-Sylow subgroup $P$. Assume $G$ is realizable over $k$. Then there is a subgroup $H \leq G$ that contains $P$ and is realizable over $m$.

The question as to whether the non-sensitivity assumption can be removed remains open. However, the assumption that the Sylow subgroup is normal is essential:

Example 1.7. Let $G = C_7 \rtimes D$ where
\[ D = \langle a, b \mid a^7 = b^9 = 1, a^{-1}ba = b^7 \rangle; \]
thus the 7-Sylow subgroups of $G$ are neither normal nor metacyclic.

In Example 4.11 we show there exists an extension $m/k$ of 7-adic fields such that $G$ is realizable over $k$, although no subgroup of $G$ that contains a 7-Sylow subgroup is realizable over $m$.

We say that an extension of number fields $M/K$ is sensitive if it has a sensitive completion. The main theorem follows from Theorem 1.6 by combining the local data (see Subsection 5.1):

Theorem 1.8. Let $M/K$ be a non-sensitive extension of number fields. Let $G$ be a group for which every Sylow subgroup is either normal or metacyclic, and the 2-Sylow subgroups are metacyclic.

Assume $G$ is $K$-admissible and has the GN-property over $M$. Then $G$ is $M$-admissible if and only if $G$ satisfies Liedahl’s condition over $M$.

Let $\mu_n$ denote the set of $n$-th roots of unity. As a consequence of Theorem 1.8 and [13, Corollary 2] we have:
Corollary 1.9. Let $G$ be an odd order group for which every Sylow subgroup is either normal or metacyclic. Let $M/K$ be a non-sensitive extension of number fields so that $G$ is $K$-admissible and $\mu_{|G|} \cap M = \{1\}$. Then $G$ is $M$-admissible if and only if $G$ satisfies Liedahl’s condition over $M$.

In particular, if every prime dividing $|G|$ decomposes in $M$ or if $M \cap \mathbb{Q}(\mu_{|G|}) = K \cap \mathbb{Q}(\mu_{|G|})$, then $G$ is $M$-admissible.

We also show that the assumption that every Sylow subgroup is either normal or metacyclic is essential in Theorem 1.8:

Example 1.10. Let $G$ be the group defined in Example 1.7. In Example 5.7, we show furthermore that there is an extension of number fields $M/K$ so that $G$ is $K$-admissible, satisfies Liedahl’s condition over $M$, has the GN-property over $M$, but is not $M$-admissible.

As an example we use Theorem 1.8 to understand the behavior of admissibility for a specific group (see Example 5.4):

Example 1.11. Let $K = \mathbb{Q}(\sqrt{14})$ and $G = C_{13} \wr M_{3^3}$, where $M_{3^3}$ is the modular group
$$
\langle x, y \mid x^{-1}yx = y^4, x^3 = y^9 = 1 \rangle,
$$
and $\wr$ is the standard wreath product. In Example 5.4, we show $G$ is $K$-admissible and deduce from Theorem 1.8 that for a number field $M \supseteq K$, $G$ is $M$-admissible if and only if $G$ satisfies Liedahl’s condition. We therefore deduce the admissibility behavior in Figure 1 by checking Liedahl’s condition.

Similar examples (also given in Example 5.4) show that the rank (the minimal number of generators) of the $p$-Sylow subgroups of $K$-admissible groups is not bounded (as opposed to the case of admissible $p$-groups discussed in [19, Section 10]).
The basic facts about admissibility of groups over number fields are reviewed in Section 2. We also discuss the behavior of wild and tame admissibility under extension of number fields and the connection between these types of admissibility to parts (i) and (ii) (respectively) in Liedahl’s condition.

The authors are grateful to Jack Sonn for his valuable advice and useful comments.

2. Preliminaries

2.1. Admissibility and Preadmissibility. For a prime \( v \) of a field \( K \), we denote by \( K_v \) the completion of \( K \) with respect to \( v \). If \( L/K \) is a finite Galois extension, \( L_v \) denotes the completion of \( L \) with respect to some prime divisor of \( v \) in \( L \).

The basic criterion for admissibility over global fields is due to Schacher:

**Theorem 2.1 (Schacher, [19]).** Let \( L/K \) be a finite Galois extension of global fields. Then \( L \) is \( K \)-adequate if for every rational prime \( p \) dividing \(|G|\), where \( G = \text{Gal}(L/K) \), there is a pair of primes \( v_1, v_2 \) of \( K \) such that each of \( \text{Gal}(L_v/K_{v_i}) \) contains a \( p \)-Sylow subgroup of \( G \).

Extracting the necessary local conditions for \( K \)-admissibility from Theorem 2.1, we arrive at the following definition. For a group \( G \), \( G(p) \) denotes a \( p \)-Sylow subgroup.

**Definition 2.2.** Let \( K \) be a number field. The group \( G \) is \( K \)-preadmissible if \( G \) is realizable over \( K \), and there exists a finite set \( S = \{v_i(p) : p \mid |G|, i = 1, 2\} \) of primes of \( K \), and, for each \( v \in S \), a subgroup \( G^v \subseteq G \), such that

1. \( v_1(p) \neq v_2(p) \) for every \( p \) dividing \(|G|\),
2. \( G^{v_i(p)} \supseteq G(p) \) for every \( p \) and \( i = 1, 2 \), and
3. \( G^v \) is realizable over \( K_v \) for every \( v \in S \).

(Notice that a \( p \)-group \( G \) is \( K \)-preadmissible if and only if there is a pair of primes \( v_1 \) and \( v_2 \) of \( K \), such that \( G \) is realizable over \( K_{v_1} \) and over \( K_{v_2} \)).

Clearly, every \( K \)-admissible group is also \( K \)-preadmissible. However the opposite does not always hold (see [11, Example 2.14]).

For an extension of fields \( L/K \), \( \text{Br}(L/K) \) denotes the kernel of the restriction map \( \text{res}: \text{Br}(K) \to \text{Br}(L) \). For number fields we have the following isomorphism of groups, where \( \Pi_K \) is the set of places of \( K \):

\[
\text{Br}(L/K) \cong \bigoplus_{\pi \in \Pi_K} \frac{1}{\gcd_{\pi'|\pi} [L_{\pi'}:K_{\pi}]} \mathbb{Z}/\mathbb{Z},
\]

where \( (\cdot)_0 \) denotes that the sum of invariants is zero.

Over a number field \( K \), the exponent of a division algebra is equal to its degree, and so \( L \) is \( K \)-adequate if and only if there is an element of order \([L:K]\) in \( \text{Br}(L/K) \) [19, Proposition 2.1].
2.2. Tame and wild admissibility. We denote by $k_{un}$ the maximal unramified extension of a local field $k$, and by $k_{tr}$ the maximal tamely ramified extension.

The tamely ramified subgroup $\text{Br}(L/K)_{tr}$ of $\text{Br}(L/K)$ is the subgroup of algebras which are split by the tamely ramified part of every completion of $L$; namely the subgroup corresponding under the above isomorphism to

$$
\left( \bigoplus_{\pi \in \Pi_K} \frac{1}{\gcd(x|\pi)} [L_{\pi'} \cap (K_{\pi})_{tr} : K_{\pi}] \mathbb{Z}/\mathbb{Z} \right)_0
$$

Following the above local description of adequacy we define:

**Definition 2.3.** We say that a finite extension $L$ of $K$ is *tamely $K$-adequate* if there is an element of order $[L : K]$ in $\text{Br}(L/K)_{tr}$.

Likewise, a finite group $G$ is *tamely $K$-admissible* if there is a tamely $K$-adequate Galois $G$-extension $L/K$.

The structure of tamely admissible groups is related to Liedahl presentations:

For $t$ prime to $n$, let $\sigma_{t,n}$ be the automorphism of $\mathbb{Q}(\mu_n)/\mathbb{Q}$ defined by $\sigma_{t,n}(\zeta) = \zeta^t$ for $\zeta \in \mu_n$.

**Definition 2.4 ([9]).** We say that a metacyclic $p$-group has a *Liedahl presentation* over $K$, if it has a presentation

$$
\mathcal{M}(m, n, i, t) := \langle x, y \mid x^m = y^i, y^n = 1, x^{-1}yx = y^i \rangle
$$

such that $\sigma_{t,n}$ fixes $K \cap \mathbb{Q}(\mu_n)$.

**Example 2.5.** The dihedral group $D_4$ has a Liedahl presentation over $\mathbb{Q}$, but not over $\mathbb{Q}(\sqrt{-1})$. Thus $D_4$ satisfies the Liedahl condition over $\mathbb{Q}$, but not over $\mathbb{Q}(\sqrt{-1})$.

The existence of Liedahl’s presentation for a $p$-group $G$ over $K$ implies $G$ is $K$-tame-preadmissible (namely, Definition 2.2 holds with realizability within $(K_v)_{tr}$ in 2.2.(3)).

**Remark 2.6 (Liedahl, follows directly from [9, Proofs of theorems 28 and 29]).** Let $G$ be a finite group. If $G$ is realizable over infinitely many completions of $K$ (at infinitely many primes), then $G$ has a presentation as above. If $G$ is a $p$-group then the converse also holds. In addition a $p$-group is realizable over infinitely many completions of $K$ if and only if it is realizable over a completion $K_v$ at one prime $v$ that does not divide $p$.

This allows us to simplify the definition of preadmissibility by noticing that the primes $v_i(p)$, $i = 1, 2, p \mid |G|$, in Definition 2.2 can be chosen to be distinct:

**Lemma 2.7.** Let $K$ be a number field. A group $G$ is $K$-preadmissible if and only if it is realizable over $K$, and there are distinct primes $v_i(p)$, $p$ runs over the primes dividing $|G|$ and $i = 1, 2$, such that for every $p$ and $i = 1, 2$, there is a subgroup $H \leq G$ that contains a $p$-Sylow subgroup of $G$ and is realizable over $K_{v_i(p)}$. 
Proof. The if part holds by definition. To prove the only if part let
\[ T = \{ v_i(p) \mid p \mid |G|, i = 1, 2 \} \]
be a set of primes of \( K \) and for every prime \( v \in T \) a corresponding subgroup \( G^v \) so that
\begin{enumerate}
  \item \( v_1(p) \neq v_2(p) \),
  \item \( G^v \) is realizable over \( K_v \),
  \item \( G^{v_i(p)} \) contains a \( p \)-Sylow subgroup of \( G \),
\end{enumerate}
for every \( p \) dividing \( |G| \) and \( i = 1, 2 \). We shall define primes \( w_i(p) \), \( p \mid |G| \) and \( i = 1, 2 \), such that all primes are distinct and for every \( w_i(p) \) there is a subgroup of \( G \) that contains a \( p \)-Sylow subgroup of \( G \) and is realizable over \( K_{w_i(p)} \).

If \( v_i(p) \) divides \( p \) define \( w_i(p) = v_i(p) \) for any \( p \mid |G| \) and \( i = 1, 2 \). If \( v_i(p) \) does not divide \( p \) then \( G(p) \) is metacyclic and has a Liedahl presentation over \( K \) (by Remark 2.6). Thus, there are infinitely many primes \( w \) of \( K \) for which \( G(p) \) is realizable over \( K_w \). For all primes \( v_i(p) \) that do not divide \( p \) (running over both \( i \) and \( p \)) choose distinct primes \( w_i(p) \) which are not in \( T \) and for which \( G(p) \) is realizable over \( K_{w_i(p)} \) (such a choice is possible since there are infinitely many such \( w \)'s). We have chosen distinct primes \( w_i(p) \), \( p \mid |G| \) and \( i = 1, 2 \), as required. \( \Box \)

Remark 2.8. If a \( p \)-group \( G \) has a Liedahl presentation over \( M \), then \( G \) also has a Liedahl presentation over any subfield \( K \) of \( M \).

Theorem 2.9 (Liedahl [9], see also [11]). If \( G \) is tamely \( K \)-admissible, then \( G(p) \) has a Liedahl presentation over \( K \) for every prime \( p \) dividing \( |G| \).

There are no known counterexamples to the opposite implication. However, the following two results are proved for \( p \)-groups in [9, Theorem 30] and in general in [11]:

Theorem 2.10. Let \( K \) be a number field and let \( G \) be a solvable group with metacyclic Sylow subgroups. Then \( G \) is tamely \( K \)-admissible if and only if its Sylow subgroups have Liedahl presentations.

Theorem 2.11. Let \( K \) be a number field. Let \( G \) be a solvable group such that the rational primes dividing \( |G| \) do not decompose in \( K \). Then \( G \) is \( K \)-admissible if and only if its Sylow subgroups are metacyclic and have Liedahl presentations.

In particular if a solvable group is tamely \( M \)-admissible then it is also tamely \( K \)-admissible for every \( K \subseteq M \), i.e. tame admissibility goes down for solvable groups. Also, if \( G \) is solvable and any prime \( p \mid |G| \) satisfies Item (i) in Liedahl’s condition over \( M \), i.e. does not decompose in \( M \), then \( G \) is \( M \)-admissible if and only if \( G \) is tamely \( M \)-admissible.

In particular for \( M = \mathbb{Q} \) one has that any solvable group \( G \) that is \( \mathbb{Q} \)-admissible is tamely \( \mathbb{Q} \)-admissible. However over larger number fields this is no longer the case. Let us define wild \( K \)-admissibility:
**Definition 2.12.** A $G$-extension $L/K$ is wildly $K$-adequate if $L/K$ is $K$-adequate and there is a prime $p$ dividing $|G|$ such that every prime $v$ of $K$ for which

$$\text{Gal}(L_v/K_v) \supseteq G(p),$$

divides $p$. A $K$-admissible group $G$ is called wildly $K$-admissible if every $K$-adequate $G$-extension is wildly $K$-adequate.

Clearly a tamely $K$-admissible group is not wildly $K$-admissible. Theorems 2.10 and 2.11 guarantee that a solvable group which is $K$-admissible but not wildly, is tamely $K$-admissible. In particular:

**Remark 2.13.** Every $K$-admissible $p$-group which is not tamely $K$-admissible is wildly $K$-admissible. So, every non-metacyclic $K$-admissible $p$-group is wildly $K$-admissible.

### 2.3. The Grunwald-Neukirch (GN) property.

A group $G$ has the GN-property (named after Grunwald and Neukirch) over a number field $K$ if for every finite set $S$ of primes of $K$ and corresponding subgroups $G_v \leq G$ for $v \in S$, there is a Galois $G$-extension $L/K$ for which $\text{Gal}(L_v/K_v) \cong G_v$ for every $v \in S$.

The Grunwald-Wang Theorem shows that except for special cases (see [25]), abelian groups $A$ have the GN-property over $K$. A large set of examples comes from a Theorem of Neukirch [13, Corollary 2]. Let $m(K)$ denote the number of roots of unity in a number field $K$.

**Theorem 2.14 (Neukirch, [13]).** Let $K$ be a number field and $G$ a group for which $|G|$ is prime to $m(K)$. Then $G$ has the GN-property over $K$.

Another important source of examples is having a generic extension ([18, Theorem 5.9]):

**Theorem 2.15 (Saltman).** If $G$ has a generic extension over a number field $K$ then $G$ has the GN-property over $K$.

By [17], if $\mu_p \subseteq K$ then any group of order $p^3$ which is not the cyclic group of order 8 has a generic extension over $K$. In [16], many groups are proved to have a generic extension over number fields, in particular, any abelian group that does not have an element of order 8. In [16] it is also proved that the class of groups with a generic extension is closed under wreath products. In particular we have:

**Corollary 2.16 (Saltman).** Let $q$ be an odd prime and let $K$ be a number field that contains the $q$-th roots of unity. Then any iterated wreath product of odd order cyclic groups and groups of order $q^3$ has the GN-property over $K$.

For more examples see [11]. Under the assumption of the GN-property one has the following characterization of wild admissibility:

**Lemma 2.17.** Let $K$ be a number field and $G$ a $K$-admissible group that has the GN-property over $K$. Then $G$ is wildly $K$-admissible if and only if there is a prime $p \mid |G|$ for which $G(p^\alpha)$ does not have a Liedahl presentation over $K$. 

Theorem 2.19 (Jannsen, Wingberg, [7], see also [15, Theorem 7.5.10])

Moreover, $\sigma_p$ such that for every $p \mid |G|$ there is a prime $v$ of $K$ that does not divide $p$, with $\text{Gal}(L_v/K_v) \supseteq G(p)$. Then $G(p)$ has a Liedahl presentation over $L^{G(p)}$ and by Remark 2.8 $G(p_0)$ has a Liedahl presentation over $K$, contradiction.

On the other hand if all Sylow subgroups have Liedahl presentation s then by Remark 2.6 every Sylow subgroup is realizable over infinitely many completions. One can therefore choose distinct primes $\{v_i(p) \mid i = 1, 2, p \mid |G|\}$ of $K$ such that $G(p)$ is realizable over $K_{v_i(p)}$ and $v_i(p)$ $fp$ for every $p \mid |G|, i = 1, 2$. Since $G$ has the GN-property it follows that $G$ is namely $K$-admissible. \hfill \Box

2.4. Galois groups of local fields. Let $k$ be a $p$-adic field of degree $n$ over $\mathbb{Q}_p$. Let $q$ be the size of the residue field $\tilde{k}$, and let $p^\sigma$ be the size of the group of $p$-power roots of unity inside $k$. Then

1. $\text{Gal}(k_{un}/k)$ is (topologically) generated by an automorphism $\sigma$, and isomorphic to $\mathbb{Z}$;
2. $\text{Gal}(k_{ur}/k_{un})$ is (topologically) generated by an automorphism $\tau$, isomorphic to $\mathbb{Z}(p^\sigma)$ (which is the complement of $\mathbb{Z}_p$ in $\mathbb{Z}$);
3. The group $\text{Gal}(k_{ur}/k)$ is a pro-$\mathbb{Z}_p$ group generated by $\sigma$ (lifting the above mentioned automorphism) and $\tau$, subject to the single relation $\sigma^{-1} \tau \sigma = \tau^q$.

Moreover, $\sigma$ and $\tau$ act on $\mu_{p^n}$ by exponentiation by some $g \in \mathbb{Z}_p$ and $h \in \mathbb{Z}_p$, respectively (Note that $g$ and $h$ are well defined modulo $p^n$).

Let $\overline{G_k(p)}$ denote the Galois group $\text{Gal}(m/k)$, where $m$ is the maximal $p$-extension of $k$ inside a separable closure $k$. Let $p^{\sigma_0}$ be the number of roots of unity of $p$-power order in $k$. Note that if $p^{\sigma_0} \neq 2$ then $n$ must be even. The following Theorem summarizes results of Shafarevich [23], Demushkin [3], Serre [21] and Labute [8]:

Theorem 2.18 ([22, Section II.5.6]). When $p^{\sigma_0} \neq 2$, $\overline{G_k(p)}$ has the following presentation of pro-$p$ groups:

$$\overline{G_k(p)} \cong \left\{ \langle x_1, \ldots, x_{n+2} \mid x_1^{2^{s_0}} [x_1, x_2] \cdots [x_{n+1}, x_{n+2}] = 1 \rangle, \quad \text{if } s_0 > 0 \right\} \cup \left\{ \langle x_1, \ldots, x_{n+2} \rangle, \quad \text{if } s_0 = 0 \right\}$$

When $p^{\sigma_0} = 2$ and $n$ is odd,

$$\overline{G_k(p)} \cong \langle x_1, \ldots, x_{n+2} \mid x_1^2 [x_1, x_2] x_2^2 [x_2, x_3] \cdots [x_{n+1}, x_{n+2}] = 1 \rangle,$$

otherwise there is an $f \geq 2$ for which $\overline{G_k(p)}$ has one of the pro-$p$ presentations:

$$\langle x_1, \ldots, x_{n+2} \mid x_1^2 [x_1, x_2] x_2^2 [x_3, x_4] \cdots [x_{n+1}, x_{n+2}] = 1 \rangle,$$

or

$$\langle x_1, \ldots, x_{n+2} \mid x_1^2 [x_1, x_2] \cdots [x_{n+1}, x_{n+2}] = 1 \rangle.$$
if $n$ is even, and
\[ G_k = \langle \sigma, (\tau)p, (x_0, \ldots, x_n) \mid \tau^a = \tau, \]
\[ x_0^a = \langle x_0, \tau \rangle^a x_1^a [x_1, y_1] [x_2, x_3] \cdots [x_{n-1}, x_n] \]
if $n$ is odd, where $(\tau)p$ denotes that $\tau$ is a pro-$p'$ element (has order prime to $p$ in every finite quotient), and $(x_0, \ldots, x_n)^N_p$ denotes the condition that the closed normal subgroup generated by $x_0, \ldots, x_n$ is required to be a pro-$p$ group. Here, the closed subgroup generated by $\sigma$ and $\tau$ is isomorphic to $\text{Gal}(k_n/k)$.

The notation $\langle x_0, \tau \rangle$ stands for $(x_0, \tau x_0 \tau^{-1}, \ldots, x_0 \tau^{n-1})$, where $\pi_p \in \hat{\mathbb{Z}}$ is an element such that $\pi_p \mathbb{Z} = \mathbb{Z}_p$. Also, $y_1$ is a multiple of $x_1^{\tau_2^{p+1}}$ by an element in the maximal pro-$p$ quotient of the pro-finite group generated by $x_1, \sigma^{\tau_2}$ and $\tau^{\tau_2}$. In particular, in every pro-odd quotient of $G_k$, $[x_1, y_1]$ is trivial.

Remark 2.20. Notice that $G_k$ is a semidirect product of a pro-$p$ group $P_k$ and a profinite metacyclic group $D_k$, where $P_k$ is the closed normal subgroup generated by $x_0, \ldots, x_n$ and $D_k$ is the closed subgroup generated by $\sigma$ and $\tau$.

The $p$-Sylow subgroup of $G_k$ is therefore the pro-$p$ closure of $\langle \sigma^{\tau_2} \rangle \cdot P_k$.

Remark 2.21. If $G$ is admissible over a number field $K$, then for every $p$ there is a subgroup $H \supseteq G(p)$ which is realizable over a completion of $K$. In particular, $H$ is a product of a metacyclic group and a normal $p$-subgroup.

The following result on realizability of metacyclic $p$-groups will be used in Section 5.

**Lemma 2.22.** Let $k$ be a $p$-adic field. Then any metacyclic $p$-group $G$ is realizable over $k$.

**Proof.** Let $G = \mathcal{M}(m, n, i, t)$ (see (2.2)). The proof for $k \neq \mathbb{Q}_p$ is in [12]. For $k = \mathbb{Q}_p$ we cover 2-groups, so $m$ and $n$ are 2-powers and $t$ is odd. In this case $G_k(2)$ has the pro-2 presentation $\langle a, b, c \mid a^2 b^4 [b, c] = 1 \rangle$ (by Theorem 2.18), i.e. $G_k(2)$ is isomorphic to the free pro-2 group on three generator modulo the normal closure of the single relation. So the map $\phi : G_k(2) \to G$ defined by:

\[ a \mapsto x^{-2} y^s, \quad b \mapsto x, \quad c \mapsto y, \]

is well defined (and surjective) whenever $(x^{-2} y^s)^2 x^4 [x, y] = 1$.

As $t$ is odd, $t^2 + 1 \equiv 2$ (mod 4), $\frac{t^2 + 1}{2}$ is odd and we can choose an $s \equiv \frac{1}{t^2 + 1} \frac{1}{2} \frac{k - 1}{2}$ (mod n) so that $s(t^2 + 1) \equiv \frac{1}{2}t^4$ (mod $n$). For such $s$ one has:

\[ (x^{-2} y^s)^2 x^4 [x, y] = x^{-4} y^{s(t^2 - 1)} x^4 y^{t-1} = y^{s(t^2 + 1)t^4 + t - 1} = 1. \]

Thus $\phi$ is well defined. \(\square\)

### 3. $p$-Groups

A nilpotent group $G$ is $K$-admissible if and only if all Sylow subgroups of $G$ are $K$-admissible. In particular studying the behavior of the admissibility of $G$ under extension of number fields is reduced to understanding the behavior of its Sylow subgroups.
3.1. The case $p$ odd. We begin by proving the observation on realizability over extensions of $p$-adic fields, $p$ odd.

**Proof of Proposition 1.2.** Let $n$ denote the rank $[k: \mathbb{Q}_p]$ and let $t = [m:k]$. If $t = 1$ there is nothing to prove. For $t = 2$, $([m:k], p) = 1$ and hence from a $G$-extension $I/k$ we can form a $G$-extension $lm/m$. Now let $t > 2$. It suffice to show that $G_k(p)$ is a quotient of $G_m(p)$.

By Theorem 2.18, $G_k(p)$ and $G_m(p)$ have the following presentations of pro-$p$ groups:

$$G_k(p) \cong \left\{ \left( x_1, \ldots, x_{n+2} \mid x_1^{p^{s_0}} [x_1, x_2] \cdots [x_{n+1}, x_{n+2}] = 1 \right), \quad \text{if } s_0 > 0 \right\},$$

and

$$G_m(p) \cong \left\{ \left( x_1, \ldots, x_{nt+2} \mid x_1^{p^{s_0}} [x_1, x_2] \cdots [x_{nt+1}, x_{nt+2}] = 1 \right), \quad \text{if } s_0' > 0 \right\},$$

where $p^{s_0}$ and $p^{s_0'}$ are the numbers of $p$-power roots of unity in $k$ and $m$, respectively. Clearly $s_0 \leq s_0'$. Let $F_p(y_1, \ldots, y_k)$ denote the free pro-$p$ group of rank $k$ with generators $y_1, \ldots, y_k$. If $s_0 = 0$ then we are done since $F_p(x_1, \ldots, x_{n+1})$ is a quotient of $F_p(x_1, \ldots, x_{nt+1})$.

Suppose $s_0 > 0$. Let $\phi : G_m(p) \to F_p(y_1, \ldots, y_{\frac{nt+2}{2}})$ be the epimorphism defined by $\phi(x_{2i-1}) = 1$ and $\phi(x_{2i}) = y_i$, $i = 1, \ldots, \frac{nt+2}{2}$. Now as $t > 2$ we have:

$$nt + 2 = n \frac{t+2}{2} + 1 \geq n + 2$$

and hence there is a projection $\pi$:

$$\pi : F_p(y_1, \ldots, y_{\frac{nt+2}{2}}) \to G_k(p).$$

Thus $\pi \circ \phi : G_m(p) \to G_k(p)$ is an epimorphism. We deduce that every epimorphic image of $G_k(p)$ is also an epimorphic image of $G_m(p)$. \hfill \Box

We can now prove Proposition 1.3. It suffices to prove:

**Proposition 3.1.** Let $M/K$ be an extension of number fields. Let $p$ be an odd prime and $G$ a $p$-group that is $K$-admissible and has the GN-property over $M$. If $G$ satisfies Liedahl's condition over $M$, then $G$ is $M$-admissible.

**Proof.** As $G$ is $K$-admissible, $G$ is realizable over $K_{v_1}, K_{v_2}$ for two primes $v_1, v_2$ of $K$. We claim there are two primes $w_1, w_2$ of $M$ for which $G$ is realizable over $M_{v_1}, M_{v_2}$. Since $G$ has the GN-property over $M$ proving the claim shows $G$ is $M$-admissible. There are two cases:

Case I: $p$ decomposes in $M$. If one of the primes $v_1, v_2$ does not divide $p$, then $G$ is metacyclic and hence by Lemma 2.22, $G$ is realizable over any $M_{w_1}, M_{w_2}$ for any two primes $w_1, w_2$ of $M$ that divide $p$. If on the other hand both $v_1, v_2$ divide $p$ then by Proposition 1.2, $G$ is realizable over $M_{w_i}$ for $w_i|v_i$, $i = 1, 2$. 

\hfill Documenta Mathematica 18 (2013) 359–382
Case II: $p$ does not decompose in $M$. Since $G$ satisfies Liedahl’s condition over $M$, $G$ has a Liedahl presentation over $M$. In particular by Theorem 2.11, $G$ is $M$-admissible.

As a corollary we deduce that wild admissibility goes up for $p$-groups:

**Corollary 3.2.** Let $p$ be an odd prime. Let $M/K$ be an extension of number fields and $G$ a wildly $K$-admissible $p$-group that has the GN-property over $M$. Then $G$ is also wildly $M$-admissible.

**Proof.** Since $G$ is wildly $K$-admissible, $p$ decomposes in $K$ and hence in $M$. Thus $G$ satisfies Liedahl’s condition over $M$ and by Proposition 3.1 $G$ is $M$-admissible. By remarks 2.6 and 2.13, the wild $K$-admissibility of $G$ implies that $G$ is not realizable over $K_v$ for any prime $v$ which does not divide $p$. By Remark 2.8, $G$ is also not realizable over $M_w$ for any prime $w$ of $M$ which does not divide $p$. Therefore an $M$-adequate $G$-extension must also be wildly $M$-admissible. □

Apply Theorem 2.14, we have:

**Corollary 3.3.** Let $p$ be an odd prime. Let $M/K$ be an extension of number fields so that $M$ does not contain the $p$-th roots of unity. Let $G$ be a $p$-group that is wildly $K$-admissible. Then $G$ is wildly $M$-admissible.

3.2. The case $p = 2$. As in Proposition 1.2 we have:

**Lemma 3.4.** Let $m/k$ is a finite extension of $2$-adic fields, which is either of degree greater than $2$, or such that $m$ and $k$ contain $\sqrt{-1}$ and have the same $2$-power roots of unity. Then any $2$-group realizable over $k$ is also realizable over $m$.

**Proof.** If $[m:k] > 2$, the same proof as of Proposition 1.2 holds in all cases of Theorem 2.18. If $\sqrt{-1} \in k$, and $k$ and $m$ have the same number of $2$-power roots of unity then $G_k(p)$ and $G_m(p)$ have the same type of presentations in Theorem 2.18 and one can obtain an epimorphism: $G_m(p) \rightarrow G_k(p)$ simply by dividing by the redundant generators of $G_m(p)$. □

However, we show that Proposition 1.2 may fail for $p = 2$. We begin with some group-theoretic preparations.

**Lemma 3.5.** The group

$$G = \langle a_1, a_2, a_3 \mid G' \text{ is central of exponent } 2, \quad a_1^2 = [a_2, a_3], \quad a_2^2 = a_3^2 = 1 \rangle$$

is not a quotient of the pro-$2$ group

$$\Gamma = \langle x_1, \ldots, x_4 \mid x_1^2[x_1,x_2][x_3,x_4] = 1 \rangle.$$

**Proof.** For $j,k = 1,2,3$, write $\alpha_{j,k} = [a_j, a_k] \in G$. Suppose $x_i \mapsto a_1^{h_i} a_2^{h_2} a_3^{h_3} z_i$ ($i = 1, \ldots, 4$) is an epimorphism $\Gamma \rightarrow G$, where $z_i \in G'$. Then $[x_2i-1, x_2i] \mapsto$
\[
\prod_{j,k=1}^{3}[a_{j_1k_1}, a_{j_2k_2}, a_{j_3k_3}] = \prod_{1 \leq k < j \leq 3} a_{j,k}^{t_{21-1,k}t_{21,k}t_{22-1,j}t_{22,j}}.
\]
Since \( \exp(G) = 4 \), the defining relation of \( \Gamma \) translates to
\[
\prod_{1 \leq k < j \leq 3} a_{j,k}^{t_{21-1,k}t_{21,k}t_{22-1,j}t_{22,j}} = 1,
\]
from which it follows that \( t_{1,j}t_{2,k} - t_{1,k}t_{2,j} + t_{3,j}t_{4,k} - t_{3,k}t_{4,j} \equiv 0 \pmod{2} \) for every \( 1 \leq k < j \leq 3 \).

Let \( V \) denote the vector space \( \mathbb{F}_2^4 \), endowed with the bilinear form \( b: V \times V \to \mathbb{F}_2 \) defined by \( b((v_1)_{i=1}^4, (v'_i)_{i=1}^4) = v_1v'_1 + v_2v'_2 + v_3v'_3 - v_4v'_4 \). This is an alternating non-degenerate form (in fact, hyperbolic), and letting \( \vartheta \in V \) be the vectors \( \vartheta_1 = t_{i,j} \), we have that \( b(\vartheta, \vartheta) = 0 \) for every \( j, k = 1, 2, 3 \). It follows that \( T = \text{span} \{ \vartheta_1, \vartheta_2, \vartheta_3 \} \subset V \) is orthogonal to itself. But then \( \dim T \leq \frac{1}{2} \dim V = 2 \), contradicting the assumption that the induced map \( \Gamma \to G/G' = C_2^3 \) is surjective.

**Corollary 3.6.** There is a group of order \( 2^6 \) which is realizable over \( k = \mathbb{Q}_2 \) but not over \( m = \mathbb{Q}_2(\sqrt{-1}) \).

**Proof.** As before, we construct a quotient of \( \overline{G_k(2)} \) which is not a quotient of \( \overline{G_m(2)} \). Let \( G \) and \( \Gamma \) be as in Lemma 3.5. By Theorem 2.18, \( \overline{G_m(2)} \cong \Gamma \) and
\[
\overline{G_k(2)} = \langle x_1, x_2, x_3 \mid x_1^2x_2^2x_3^2 = 1 \rangle.
\]

Mapping \( x_i \mapsto a_i \) projects \( \overline{G_k(2)} \) onto \( G \), which is not a quotient of \( \Gamma \). \( \square \)

It seems that \( 2^6 \) is the minimal possible order for such a 2-group.

**Remark 3.7.** Let \( m/k \) be an extension of local fields. If there is one 2-group which is realizable over \( k \) but not over \( m \), then there are infinitely many such groups. Indeed, let \( G \) be such a group, and let \( k' \) be a \( G \)-Galois extension of \( k \); the Galois group of any 2-extension of \( k' \) which is Galois over \( k \) has \( G \) as a quotient, and so is not realizable over \( m \).

Let us apply this example to construct an extension of number fields \( M/K \) for which the group \( G \) of Lemma 3.5 is wildly \( K \)-admissible but not \( M \)-admissible and not even \( M \)-preadmissible.

Let \( p \) and \( q \) be two primes for which:
1) \( p \equiv 5 \pmod{8} \)
2) \( q \equiv 1 \pmod{8} \)
3) \( q \) is not a square mod \( p \).

**Proposition 3.8.** Let \( K = \mathbb{Q}(\sqrt{-7}), M = K(i) \) and \( G \) be the group from Lemma 3.5. Then \( G \) is wildly \( K \)-admissible but not \( M \)-preadmissible.

**Proof.** Since \( G \) is a 2-group that is not metacyclic it is realizable only over completions at primes dividing 2. In particular if \( G \) is \( K \)-admissible then \( G \) is wildly \( K \)-admissible. As 2 splits in \( K \), any (of the two) prime divisor \( v \) of 2 in \( M \) has a completion \( M_v \cong \mathbb{Q}_2(\sqrt{-7}) \). By Corollary 3.6, \( G \) is not realizable...
Danny Neftin and Uzi Vishne

over \( \mathbb{Q}_2(i) \) and hence not \( M\)-preadmissible. It therefore remains to show \( G \) is \( K\)-admissible.

The rational prime \( p \) is inert in \( K \). Let \( \mathfrak{p} \) be the unique prime of \( K \) that divides \( p \). We have \( N(p) := [K_{\mathfrak{p}}] = p^2 \equiv 1 \pmod{8} \). Thus, \( K_{\mathfrak{p}} \) has a totally ramified \( C_8 \)-extension. Let \( q_1, q_2 \) be the two primes of \( K \) dividing 2.

Consider the field extension \( L_0 = K(\mu_8, \sqrt{p})/K \). It has a Galois group

\[
\text{Gal}(L_0/K) \cong C_2^2 \cong G/Z(G).
\]

This extension is ramified only at \( q_1, q_2 \) and \( \mathfrak{p} \). As \( K_{q_i} \cong \mathbb{Q}_2 \) and \( \text{Gal}(L_0_{q_i}/K_{q_i}) \cong C_2^2 \), \( (L_0)_{q_i}/K_{q_i} \) is the maximal abelian extension of \( K_{q_i} \) of exponent 2, for \( i = 1, 2 \). Note that \( N(p) \equiv 1 \pmod{8} \) and hence \( K_{\mathfrak{p}} \) contains \( \mu_8 \).

Notice that \( Z(G) = G' \cong C_2^2 \) and \( G/Z(G) \cong C_2^3 \). Let us show that the central embedding problem

\[
(3.1)
\]

has a solution. Let \( \pi \) denote the epimorphism \( G \to G/Z(G) \). By theorems 2.2 and 4.7 in [14], there is a global solution to Problem 3.1 if and only if there is a local solution at every prime of \( K \). There is always a solution at primes of \( K \) which are unramified in \( L_0 \) so it suffices to find solutions at \( \mathfrak{p}, q_1, q_2 \). Any \( G \)-extension of \( K_{q_i} \) contains \( (L_0)_{q_i} \) (as it is the unique \( C_2^3 \) extensions of \( \mathbb{Q}_2 \), \( i = 1, 2 \). Since \( G \) is realizable over \( \mathbb{Q}_2 \) we deduce that the induced local embedding problem

\[
(3.2)
\]

has a solution for \( i = 1, 2 \). Since \( (L_0)_{\mathfrak{p}} \) is the ramified \( C_2 \)-extension of \( K_{\mathfrak{p}} \), it can be embedded into the totally ramified \( C_4 \)-extension and hence the local embedding problem at \( \mathfrak{p} \) has a solution.

Therefore, Embedding problem 3.1 has a solution. Let \( L \) be the corresponding solution field. As Problem 3.1 is a Frattini embedding problem such a solution must be surjective globally and at \( \{q_1, q_2\} \). Thus, \( L_0/K \) can be embedded in a Galois \( G \)-extension \( L/K \) for which \( \text{Gal}(L_{q_i}/K_{q_i}) \cong G \), for \( i = 1, 2 \). The field \( L \) is clearly \( K \)-adequate and hence \( G \) is \( K \)-admissible.
4. Realizability under extension of local fields

Realizability of a group $G$ as a Galois group over a field $k$ is clearly a necessary condition for $k$-admissibility. When $k$ is a local field, the conditions are equivalent since a division algebra of index $n$ is split by every extension of degree $n$.

In this section we study realizability of groups under field extensions, assuming the fields are local.

4.1. Totally ramified extensions. We first note what happens under prime to $p$ local extensions:

**Lemma 4.1.** Let $G_1$ be a subgroup of $G$ that contains a $p$-Sylow subgroup of $G$ and is realizable over the $p$-adic field $k$. Let $m/k$ be a finite extension for which $([m:k], p) = 1$. Then there is a subgroup $G_2 \leq G_1$ that contains a $p$-Sylow subgroup of $G$ and is realizable over $m$.

**Proof.** Let $l/k$ be a $G_1$-extension. Then $lm/m$ is a Galois extension with Galois group $G_2$ which is a subgroup of $G_1$ and for which $[l : l \cap m] = |G_2|$. Since $([l \cap m:k], p) = 1$, any $p^r | [l:k] = |G_1|$ also divides $p^r | [l : l \cap m] = |G_2|$. Thus $G_2$ must also contain a $p$-Sylow subgroup of $G$. □

The case where $p$ divides the degree $[m:k]$ is more difficult. Let us consider next totally ramified extensions:

**Lemma 4.2.** Let $p \neq 2$. Let $G$ be a group, $k$ a $p$-adic field with $n = [k : \mathbb{Q}_p]$ and $m/k$ a totally ramified finite extension. Assume furthermore that $m/k$ is not the extension $\mathbb{Q}_3(\zeta_9 + \zeta_9)/\mathbb{Q}_3$. If $G$ is realizable over $k$ then $G$ is also realizable over $m$.

**Remark 4.3.** This shows that if $G$ has a subgroup $G_1$ that contains a $p$-Sylow of $G$ and is realizable over $k$ then we can pick $G_2 := G_1$ as a subgroup which contains a $p$-Sylow subgroup of $G$ and is realizable over $m$.

**Proof.** Let $m/k$ be a totally ramified extension of degree $r = [m:k]$. We shall construct an epimorphism $G_m \to G_k$. For this we shall consider the presentations given in Theorem 2.19. Denote the parameters of $k$ by $n, q, s, g$ and $h$. Then the degree of $m$ over $\mathbb{Q}_p$ is $nr$ and its residue degree remains $q$. Denote the rest of the parameters over $m$ by $s', g'$ and $h'$ (the parameters that correspond to $s, g$ and $h$ in Theorem 2.19). Then by Theorem 2.19, $G_m$ has the following presentation (as a profinite group):

$G_m = \langle \sigma, (\tau)^{p^r}, (x_0, \ldots, x_{nr})\rangle_p^n |$

$\tau^s = \tau^q, x_0^a = (x_0, \tau)^g x_1^{p^r} [x_1, x_2] \cdots [x_{nr-1}, x_{nr}],$

if $nr$ is even and

$G_m = \langle \sigma, (\tau)^{p^r}, (x_0, \ldots, x_{nr})\rangle_p^n |$

$\tau^s = \tau^q, x_0^a = (x_0, \tau)^g x_1^{p^r} [x_1, y] [x_2, x_3] \cdots [x_{nr-1}, x_{nr}].$
if \( nr \) is odd. Let \( P_k \) be the closed normal subgroup of \( G_k \) generated by \( x_0,\ldots,x_n \) and let \( D_k \) (resp. \( D_m \)) be the closed subgroup generated by \( \sigma \) and \( \tau \). By assumption, \( P_k \) is a pro-\( p \) group. Note that as \( k \) and \( m \) have the same residue degree (same \( q \)), \( D_k \cong D_m \).

Let us construct the epimorphism from \( G_m \) to \( G_k \). First send \( x_0 \) and every \( x_k \) with \( k \) odd in the presentation of \( G_m \) to 1. We get an epimorphism

\[
G_m \twoheadrightarrow (\sigma, (\tau)^{p, (z_1, \ldots, z_d)^N} | \sigma \tau \sigma^{-1} = \tau^q)
\]

where \( d = \lceil \frac{nr-1}{2} \rceil \) and \( \lceil \gamma \rceil \) denotes the smallest integer \( \geq \gamma \). Let us continue under the assumption \( d \geq n + 1 \). Then there is an epimorphism \( F_p(d) \twoheadrightarrow F_p(n+1) \). We therefore obtain epimorphisms:

\[
G_m \twoheadrightarrow (\sigma, (\tau)^{p, (z_1, \ldots, z_n+1)^N} | \sigma \tau \sigma^{-1} = \tau^q) \twoheadrightarrow D_k \cong P_k \twoheadrightarrow G_k.
\]

The numerical condition \( \lceil \frac{nr-1}{2} \rceil \geq n + 1 \) fails if and only if:

1. \( r = 1 \), or
2. \( r = 2 \), or
3. \( r = 3 \) and \( n = 1 \).

The case \( r = 1 \) is trivial. Since \( p \) is an odd prime, the cases \( r = 2 \) and \( r = 3 \) are done by Lemma 4.1, unless \( p = 3 \) and \( \lceil \frac{m}{k} \rceil = r = 3 \), in which case \( n = 1 \), so \( k = \mathbb{Q}_3 \). If \( m \neq \mathbb{Q}_3(\zeta_9 + \overline{\zeta}_9) \) then \( m \cap k_{tr} = k \) and the parameters \( g, h, s \) in the presentation of \( G_k \) remain the same in the presentation of \( G_m \). In such case there is an epimorphism from \( G_m \) onto \( G_k \) whose kernel is generated by \( \langle x_2, x_3 \rangle \).

So the case \( k = \mathbb{Q}_3 \) and \( m = \mathbb{Q}_3(\zeta_9 + \overline{\zeta}_9) \) remains open. This will be one of several sensitive cases.

4.2. The sensitive cases.

**Definition 4.4.** We call the extension \( m/k \) sensitive if it is one of the following:

1. \( k = \mathbb{Q}_3 \) and \( m \) is the totally ramified 3-extension \( \mathbb{Q}_3(\zeta_9 + \overline{\zeta}_9) \),
2. \( k = \mathbb{Q}_3 \) and \( m = \mathbb{Q}_5(\zeta_{11}) \) is the unramified 5-extension,
3. \( [k: \mathbb{Q}_3] = 1, 2, 3 \) and \( m/k \) is the unramified 3-extension,
4. \( k = \mathbb{Q}_3 \) and \( m = \mathbb{Q}_3(\zeta_7) \) is the unramified 6-extension.

**Remark 4.5.** There are 17 sensitive field extensions, up to isomorphism: one over \( \mathbb{Q}_5 \) and 16 over \( \mathbb{Q}_3 \). Fixing the algebraic closures of the respective \( p \)-adic fields, there is one sensitive 5-adic extension and 27 3-adic ones. This can be verified using the automated tools in [6]. We provide details in the Appendix.

Let us formulate the problem in case (1) for odd order groups:

**Remark 4.6.** Given a field \( F \) denote by \( G_F^{\text{odd}} \) the Galois group that corresponds to the maximal pro-odd Galois extension of \( F \). In the \( p \)-adic case, for odd \( p \), this is obtained from the presentation of \( G_k \) (see Theorem 2.19) simply by dividing by the 2-part of \( \sigma \) and \( \tau \). In such case we get a presentation of \( G_F^{\text{odd}} \) by identifying \( \sigma_2 = \tau_2 = 1 \). We get that \( y_1 \) is a power of \( x_1 \) and hence \( [x_1, y_1] = 1 \).
Question 4.7. Let $m/k$ be the sensitive extension (1). Then $q = 3$; also $p^s = 3$ so we can choose $h = -1$. For $m$ we have $p^m = 9$ and $\tau(\zeta_9 + \zeta_9^{-1}) = \zeta_9 + \zeta_9^{-1}$, so $h_m = -1$ as well. Theorem 2.19 gives us the presentations:

$$G_{k}^{\text{odd}} = \langle \sigma, (\tau)p, (x_0, x_1) \rangle | \text{ } \tau^p = \tau^3, \sigma = (x_0, \tau)x_1^2 \rangle,$$

while:

$$G_{m}^{\text{odd}} = \langle \sigma, (\tau)p, (x_0, x_1, x_2, x_3)^N \rangle | \text{ } \tau^p = \tau^3, \sigma = (x_0, \tau)x_1^2[x_2, x_3] \rangle,$$

where $\sigma, \tau$ are of order prime to 2 and $(x_0, \tau) = (x_0\tau x_0^{-1}\tau)^{\mathbb{F}_p}$, which has order a power of 3 in every finite quotient. Does the following hold: Let $G$ be an epimorphic image of $G_{k}^{\text{odd}}$, is there necessarily a subgroup $G(p) \leq G_0 \leq G$ so that $G_0$ is an epimorphic image of $G_{m}^{\text{odd}}$?

Note that for a 3-group $G$ the claim was proved in Proposition 1.2.

Remark 4.8. In fact quotients of $G_{k}^{\text{odd}}$ with $\tau = 1$ can be covered: the group $\langle \sigma, (x_0, x_1)^N \rangle | \text{ } x_0^p = x_0, \sigma = (x_0, \tau)x_1^2 \rangle$ is covered by $\sigma \mapsto \sigma, \tau \mapsto 1, x_0 \mapsto 1, x_1 \mapsto 1, x_2 \mapsto x_1$ and $x_3 \mapsto 1$. This corresponds to realization of $G$ over $k$ whose ramification index is a 3-power.

4.3. Extensions of local fields. We can now approach the general case. Recall the presentation of $G_k$ from Theorem 2.19. Let $P_k$ denote the closed normal subgroup generated by $x_0, \ldots, x_n$ and $D_k$ the closed subgroup generated by $\sigma$ and $\tau$, as in Remark 2.20.

Remark 4.9. (1) Decompose $\langle \sigma \rangle$ into its $p$-primary part generated by $\sigma_p$ and its complement generated by $\sigma_{p'}$ so that $\sigma = \sigma_p\sigma_{p'}$, where $[\sigma_p, \sigma_{p'}] = 1$. Then the pro-$p$ closure of $\langle \sigma_p \rangle \cdot P_k$ is a $p$-Sylow subgroup of $G_k$.

(2) In every finite quotient $\sigma_p$ is a power of $\sigma$, and so normalizes $\tau$. It follows that $[\tau, \sigma_p]$ is a power of $\tau$, and so a pro-$p'$ element.

(3) The image of the closure of $\langle \sigma_p \rangle P_k$ is normal in a quotient of $G_k$ if and only if $\tau$ conjugates $\sigma_p$ into the closure of $\langle \sigma_p \rangle P_k$; but then the image of $[\tau, \sigma_p]$ is a pro-$p$ element, so by (2) this is the case if and only if the image of $[\tau, \sigma_p]$ is trivial.

(4) Let $\tilde{G}_k$ denote the maximal quotient of $G_k$ with a normal $p$-Sylow subgroup. It follows from (3) that $\tilde{G}_k$ is defined by the relation $[\tau, \sigma_p] = 1$.

Lemma 4.10. Let $p$ be an odd prime. Let $m/k$ be an extension of $p$-adic fields with $f = [m:k]$ a $p$-power, and $\left\lceil \frac{n-1}{2} \right\rceil \geq n+2$ where $n = [k:Q_p]$ and $r = [m:k]$. Then $\tilde{G}_k$ is a quotient of $G_m$.

Proof. We construct an epimorphism from $G_m$ to $\tilde{G}_k$. Let $s_m, g_m, h_m$ be the invariants $s, g, h$ in Theorem 2.19 that correspond to $m$, and let $n = [k:Q_p]$. Theorem 2.19 gives the following presentation of $G_m$:

$$G_m = \langle \sigma, (\tau)p, (x_0, \ldots, x_n)^N \rangle | \text{ } \tau^p = \tau^q, x_0^p = (x_0, \tau)x_1^2[x_1, x_2] \cdots [x_{nr-1}, x_{nr}] \rangle,$$
if \( nr \) is even and
\[
G_m = \langle \sigma, (\tau)_{p'}, (x_0, \ldots, x_{nr})^{N}_{p} \mid \tau' = \tau'^f, x_0^\sigma = (x_0, \tau)^{m_{p'}} x_1^{m_{p'}} [x_1, y_1] [x_2, x_3] \cdots [x_{nr-1}, x_{nr}] \rangle,
\]
if \( nr \) is odd.
Let \( P_k \) (resp. \( P_m \)) be the closed normal subgroup generated by \( x_0, \ldots, x_n \) (resp. \( x_0, \ldots, x_{nr} \)) in \( G_k \) (resp. \( G_m \)) and let \( D_k \leq G_k \) (resp. \( D_m \leq G_m \)) be the closed subgroup generated by \( \sigma, \tau \) in \( G_k \) (resp. in \( G_m \)).
Set \( d = \left\lceil \frac{nr}{2} \right\rceil \), so by assumption \( d \geq n + 2 \). Similarly to Lemma 4.2 (noting that this time \( D_m \) can be viewed as a subgroup of index \( f \) in \( D_k \)), we have an epimorphism
\[
G_m \rightarrow \langle \sigma, (\tau)_{p'}, (z_1, \ldots, z_{m})^{N}_{p} \mid \tau' = \tau'^f \rangle \\
\cong \langle (\sigma)_{p'}, (\sigma')_{p'}, (\tau)_{p'}, (z_1, \ldots, z_{m})^{N}_{p} \mid \tau^\sigma \sigma' = \tau'^f, [\sigma, \sigma'] = 1 \rangle.
\]
Let us divide by the relations \( z_0^f = \sigma \) and \( \tau^m = \tau^\sigma \sigma^{-1} \), where \( \sigma^{-1} \) is well defined since \( f \) is a \( p \)-power. We then obtain an epimorphism to
\[
\langle (\sigma')_{p'}, (\tau)_{p'}, (z_1, \ldots, z_{m})^{N}_{p} \mid \tau^m = \tau^\sigma \sigma'^{-1} f, [z_m, \sigma'] = 1 \rangle.
\]
Adding the relation \([z_m, \sigma']\) and sending \( z_m \mapsto \sigma \) maps this group onto
\[
\langle (\sigma')_{p'}, (\tau)_{p'}, (z_1, \ldots, z_{m-1}, \sigma)_{p'}^{N}_{p} \mid \tau^\sigma \sigma'^{-1} f = \tau^q, [\sigma, \sigma'] = 1 \rangle.
\]
Mapping \( \sigma' \mapsto \sigma'^f \), this groups maps onto
\[
\langle (\sigma)_{p'}, (\sigma')_{p'}, (\tau)_{p'}, (x_0, \ldots, x_{n})^{N}_{p} \mid \tau^\sigma \sigma' = \tau^q, [\sigma, \sigma'] = [\sigma, \tau] = 1 \rangle,
\]
since by Remark 4.9 the assumption that the normal subgroup generated by \( \sigma \) is a \( p \)-group is equivalent to \( [\sigma, \tau] = 1 \).
But \( G_k \) is a quotient of this group by Theorem 2.19 and Remark 4.9.(4).

Using Lemma 4.10, we can prove:

**Proof of Theorem 1.6.** Let \( n, q \) be as defined above for \( k \), and let \( r = [m:k] \).
Let \( f = [m:k] = f_p f_{p'} \) where \( f_p \) is a \( p \)-power and \( f_{p'} \) is prime to \( p \). There is an unramified \( C_f \)-extension \( m'/k \) which lies in \( m \), and then \( m/m' \) is totally ramified. Denote by \( m_p \) the subfield of \( m' \) which is fixed by \( C_{f_p} \). Let \( r' = \frac{m'}{m} = [m:m_p] \). By Lemma 4.1, there is a subgroup \( G_0 \leq G \) that contains a \( p \)-Sylow subgroup of \( G \) and an epimorphism \( \phi : G_{m_p} \rightarrow G_0 \). The list of sensitive cases satisfies that if \( m/k \) is non-sensitive and \( m_p/k \) is unramified and prime to \( p \), then \( m/m_p \) is also non-sensitive and therefore we can assume without loss of generality that \( m_p = k \), \( G = G_0 \), i.e \( f_{p'} = 1, f = f_p \), and \( r' = r \).
If \( \left\lceil \frac{m-1}{2} \right\rceil \geq n + 2 \) then \( G \) is a quotient of \( G_m \) by Lemma 4.10. This numerical condition fails if and only if
- (1) \( r = 4, 5 \) and \( n = 1 \);
- (2) \( r = 3 \) and \( n = 1, 2, 3 \);
- (3) \( r = 1, 2 \).

---

*Documenta Mathematica 18 (2013) 359–382*
The cases \( r = 1, 2, 4 \) are covered by Lemma 4.1. We are left with cases \( r = 3, 5 \). For \( r = 5 \), \( n = 1 \) so \( k = \mathbb{Q}_3 \) and by Lemma 4.2 we may assume \( m/k \) is not totally ramified, so \( m/k \) is the unramified 5-extension which is sensitive.

Let \( r = 3 \). Lemma 4.1 covers the case \( p \neq 3 \), so we may assume \( p = 3 \).

Note that \( f | r \). If \( f = 1 \), Lemma 4.2 applies, except for \( m = \mathbb{Q}_3(\zeta_9 + \zeta_9) \) and \( k = \mathbb{Q}_3 \), which is sensitive. If \( f = 3 \), then \( m/k \) is the unramified 3-extension and \( n = [k: \mathbb{Q}_3] = 1, 2, 3 \) which are all sensitive. \( \square \)

The following example shows that the assumption in Theorem 1.6 that the normal \( p \)-Sylow subgroup of \( G \) is normal, is essential.

**Example 4.11.** Let \( p < q \) be odd primes such that \( p^q \equiv 1 \pmod{q} \) and \( p \neq 1 \pmod{q} \) (for example \( p = 7 \) and \( q = 29 \)). Let \( G = C_p \ast D \) where

\[
D = \langle a, b \mid a^p = b^q = 1, a^{-1}ba = b^p \rangle.
\]

Let \( k = \mathbb{Q}_p \) and \( m/k \) the unramified extension of degree \( p \). Then \( G \) is realizable over \( k \) but there is no subgroup of \( G \) that contains a \( p \)-Sylow subgroup of \( G \) and is realizable over \( m \).

**Proof.** Let \( P = C_p^p \), so that \( G = P \times D \). Then one has the projections

\[
G_k \to G_k^{\text{odd}} = \langle (\sigma, (\tau)_p', (x_0, x_1)_p^N \mid \tau^\sigma = \tau^p, x_0^\sigma = (x_0, \tau)x_1^p \rangle \to \langle (\sigma, (\tau)_p', (x_1)_p^N \mid \tau^\sigma = \tau^p, x_1^p = 1 \rangle,
\]

where the latter two group are pro-odd and the second epimorphism is obtained by dividing by \( x_0 \). The latter group maps onto \( G \) by \( \sigma \mapsto a \) and \( \tau \mapsto b \). It is therefore left to prove that for any homomorphism \( \phi : G_m \to G \), \( \text{Im}(\phi) \) does not contain a \( p \)-Sylow subgroup of \( G \). Assume on the contrary that \( H = \text{Im}(\phi) \) does. Recall:

\[
G_m = \langle (\sigma, (\tau)_p', (x_0, \ldots, x_p)_p^N \mid \tau^\sigma = \tau^p, x_0^\sigma = (x_0, \tau)x_1^p[x_1, y_1][x_2, x_3] \cdots [x_{p-1}, x_p] \rangle.
\]

Since \( q \) is the only prime dividing \( |G| \) other than \( p \), and \( \tau \) is pro-\( p' \), any map into \( G \) must split through:

\[
G_m \to \langle (\sigma, (\tau)_p', (x_0, \ldots, x_p)_p^N \mid \sigma, \tau = 1, \tau^q = 1, x_0^\sigma = (x_0, \tau)x_1^p[x_1, y_1][x_2, x_3] \cdots [x_{p-1}, x_p] \rangle.
\]

However the latter group has a normal \( p \)-Sylow subgroup which is the product of the closed normal subgroup generated by the \( x_i \)'s and the pro-\( p \) group generated by \( \sigma^q \). In particular, letting \( \pi : G \to G/P = D \) be the projection, the image of \( \pi\phi \) has a normal \( p \)-Sylow subgroup. This implies \( \pi\phi \) is not surjective. But \( H \) contains a \( p \)-Sylow subgroup of \( G \), so we must have \( \text{Im}(\pi\phi) = C_p \). Again since \( H \) contains a \( p \)-Sylow subgroup, and in particular \( P \), we must have \( H = P \times C \) where \( C = C_p \) is a subgroup of \( D \) and the action of \( C \) on \( P \) is induced from the action of \( D \). Thus:

\[
\text{rank}(H) = \text{rank}(H/[H, H]) = \text{rank}((P/[P, C]) \times C) = q + 1.
\]
Since $H$ is a $p$-group any epimorphism to it must split through $G_m(p)$. However
rank$(G_m(p)) = [m:k] + 1 = p + 1$, leading to a contradiction. \hfill $\Box$

5. Extensions of number fields

We shall now apply Theorem 1.6 to study admissibility and wild admissibility.

5.1. Main Theorem.

Proof of Theorem 1.8. As mentioned in the introduction, Liedahl’s condition is
necessary. Let us show that if $G$ satisfies this condition then $G$ is $M$-admissible.
We claim that one can choose distinct primes $w_i(p)$, $i = 1, 2, p | |G|$, of $M$ and
and corresponding subgroups $H_i(p) \leq G$ so that $H_i(p)$ contains a $p$-Sylow subgroup
of $G$ and is realizable over $M_{w_i(p)}$, $i = 1, 2$.
As $G$ is $K$-admissible, for every $p | |G|$ there are two options:

1) there are two primes $v_1, v_2$ of $K$ dividing $p$ and two subgroups $G(p) \leq
G_i \leq G$ so that $G_i$ is realizable over $K_v$, $i = 1, 2$.

2) $G(p)$ is realizable over $K_v$ for $v$ which does not divide $p$.

In case (1) with $p$ odd and $G(p)$ normal in $G$, by Theorem 1.6, for any prime
$p$ dividing $v_1$ or $v_2$ there is a subgroup $G(p) \leq H_w \leq G$ that is realizable
over $M_w$. Choose two such primes $w_1(p), w_2(p)$ and set $H_i(p) := H_w(w_i(p))$ (the
subgroups Theorem 1.6 constructs). In case $G(p)$ is not normal or $p = 2$, we
assumed $G(p)$ is metacyclic and by Lemma 2.22, $G(p)$ is realizable over any
$M_w$ for any prime $w$ dividing $v_1$ or $v_2$. In such case similarly choose two such
primes $w_1(p), w_2(p)$ and set $H_i(p) = G(p)$.
In case (2), $G(p)$ is metacyclic. If $p$ has more than one prime divisor in $M$ then
there are two primes $w_1(p), w_2(p)$ so that $w_i(p)$ divides $p$ and by Lemma 2.22
$H_i(p) := G(p)$ is realizable over $M_{w_i(p)}$, $i = 1, 2$.
If $p$ has a unique prime divisor in $M$ then $G(p)$ is assumed to have a Liedahl
presentation. Liedahl’s condition implies that there are infinitely many primes
$w(p)$ for which $G(p)$ is realizable over $M_{w(p)}$ (see Theorem 28 and Theorem 30
in [9]). Thus, we can choose two primes $w_1(p), w_2(p)$ for every prime $p | |G|
that has only one prime divisor in $M$, so that the primes $w_i(p)$, $i = 1, 2$, are not
divisors of any prime $q | |G|$ and are all distinct. For such $p$, we also choose
$H_i(p) := G(p)$.
We have covered all cases of behavior of divisors of rational primes in $M$ and
hence proved the claim. It follows that $G$ is $M$-preadmissible and as $G$ has the
GN-property over $M$, $G$ is $M$-admissible. \hfill $\Box$

Remark 5.1. If $G$ has metacyclic Sylow subgroups, the proof of Theorem 1.8
does not use Theorem 1.6 and holds for sensitive extensions as well.

5.2. Wild admissibility. As to wild admissibility Theorem 1.8 and
Lemma 2.17 give:

Corollary 5.2. Let $M/K$ be a non-sensitive extension. Let $G$ be a $K$-
admissible group for which every Sylow subgroup is either normal or metacyclic
and the 2-Sylow subgroups are metacyclic. Assume $G$ has the GN-property over

\textbf{Documenta Mathematica 18 (2013) 359–382}
M, satisfies Liedahl’s condition over M but there is a prime p for which G(p) does not have a Liedahl presentation over M. Then G is wildly M-admissible.

We deduce that for groups as in Theorem 1.8, wild admissibility goes up in the following sense that generalizes Corollary 3.2:

**Corollary 5.3.** Let M/K be a non-sensitive extension. Let G be a wildly K-admissible group for which every Sylow subgroup is either normal or metacyclic and the 2-Sylow subgroups are metacyclic. Assume G has the GN-property over K and M satisfies Liedahl’s condition over M. Then G is wildly M-admissible.

**Proof.** By Theorem 1.8, G is M-admissible. The assertion now follows from Lemma 2.17, applied to both K and M, and the fact that if G(p) does not have a Liedahl presentation over K then G(p) does not have a Liedahl presentation over M (see Remark 2.8). □

5.3. **Examples.** The following is an example in which Theorem 1.8 is used to understand how admissibility behaves under extensions of a given number field:

**Example 5.4.** Let p, q be odd primes and m an integer so that m is not square mod q but is a square mod p and p ≡ q + 1 (mod q^2). For example p = 13, q = 3, m = 14. Let K = Q(√m) and G = C_p ⋊ H, where H is one of the following groups:

1. H = M_q^3 is the modular group of order q^3, i.e.
   \[ H = \langle x, y|x^{-1}yx = y^{q+1}, x^q = y^{q^2} = 1 \rangle. \]

2. H = C_{pq} × C_q.

3. H = C_t where t ∈ N_{odd} is prime to p.

We shall show in each of the cases G is K-admissible. Let M be any non-sensitive extension of K.

By Theorem 2.14, in case (1) G satisfies the GN-property over any number field that does not have any p-th and q-th roots of unity, in particular over K. By Corollary 2.16, in cases (2),(3), G satisfies the GN-property over any M and in case (1) if M contains the q-th roots of unity.

In cases (2),(3), G satisfies Liedahl’s condition over any M and in case (1), G satisfies Liedahl’s condition over M if and only if q decomposes in M or M ∩ Q(μ_{q^2}) ⊆ Q(μ_q).

It follows from Theorem 1.8, that in cases (2) and (3) G is M-admissible. In case (1), if one assumes M does not contain any p-th and q-th roots of unity or that M contains the q-th roots of unity then G is M-admissible if and only if G satisfies Liedahl’s condition.

**Proof.** The prime p splits (completely) in K. Denote it’s prime divisors in K by v_1, v_2. Then K_{v_i} ∼= Q_p for i = 1, 2. Using the presentation of G_{odd} given in Question 4.7 and dividing by x_0 = 1 one obtains an epimorphism:

\[ G_{Q_p} \to \langle \sigma, \tau^{p^i}, (x_1)^{p^i} \mid \tau^p = \sigma, x_1^p = 1 \rangle. \]
Since $p \equiv q + 1 \pmod{q^2}$ there is an epimorphism
\[ \langle \sigma, (\tau)^p \mid \tau^c = \tau^p \rangle \to M_{q^3} \]
which together with Epimorphism 5.1 shows that $C_p \wr M_{q^3}$ is an epimorphic image of $G_{Q_p}$. The group $G$ in case 3 can obtained as an epimorphic image of $G_{Q_p}$ after dividing 5.1 by $\tau = 1$. In case 2, since $q|p - 1$, there is an epimorphism
\[ \langle \sigma, (\tau)^p \mid \tau^c = \tau^p \rangle \to C_{pq} \times C_q, \]
which together with 5.1 can be used to construct an epimorphism onto $G$.
In particular $C_p \wr H$ is realizable over $K_{v_1}, K_{v_2}$ in all cases. Since $M_{q^3}, C_q \times C_q$ and $C_r$ have Liedahl presentations over $K$, they are realizable over completions at infinitely many primes of $K$. As $G$ has the GN-property over $K$, it follows that $G$ is $K$-admissible in all cases.

Remark 5.5. As Case 3 of Example 5.4 shows, the rank of $p$-Sylow subgroups of $K$-admissible groups is not bounded as apposed to the case of admissible $p$-group in which the rank of the group is bounded (see [19, Section 10]).

Remark 5.6. Case 2 in Example 5.4 is an example of a group for which proving $M$-admissibility requires the use of all steps in the proof of Theorem 1.6.

The following example shows that the assumption that every Sylow subgroup is either normal or metacyclic is essential for Theorem 1.8 even for odd order groups and non-sensitive extensions:

Example 5.7. As in Example 4.11, let $p < q$ be odd primes such that $p^2 \equiv 1 \pmod{q}$ and $p \not\equiv 1 \pmod{q}$. Let $G = C_p \wr D$ where
\[ D = \langle a, b \mid a^p = b^q = 1, a^{-1}ba = b^p \rangle. \]
Let $d$ be a non-square integer that is a square mod $pq$ and $K = \mathbb{Q}(\sqrt{d})$. Let $v_1, v_2$ be the primes of $K$ dividing $p$. Let $M/K$ be a $C_p$-extension in which both $v_1$ and $v_2$ are inert and $M$ does not contain any $p$-th and $q$-th roots of unity. Since both $p$ and $q$ have more than one prime divisor in $M$, $G$ satisfies Liedahl’s condition over $M$. As $M$ does not contain any $p$-th and $q$-th roots of unity, by Theorem 2.14, $G$ has the GN-property over $M$ and $K$. We shall now show $G$ is $K$-admissible but not $M$-admissible. Note that the only condition of Theorem 1.8 that fails is that either $G$ has a normal $p$-Sylow subgroup or a metacyclic one.

Proof. By Example 4.11, $G$ is realizable over $\mathbb{Q}_p$ and hence over $K_{v_1}, K_{v_2}$. As $G$ has the GN-property over $K$, $G$ is $K$-admissible. On the other hand, since $G(p)$ is not metacyclic, a subgroup of $G$ that contains $G(p)$ is realizable only over completions of $M$ at prime divisors of $p$. Let $w_i$ be the prime dividing $v_i$ in $M$, $i = 1, 2$. Then $w_1, w_2$ are the only primes dividing $p$ in $M$ but by Example 4.11 $G$ is not realizable over $M_{w_i}$, for $i = 1, 2$. In particular $G$ is not $M$-preadmissible and not $M$-admissible. □
We use the Jannsen-Wingberg presentation of $G_{Q_3}$ to count the sensitive extensions, as defined in Subsection 4.2, up to isomorphism. There is a single extension in each of cases (1), (2) and (4). In case (3) the extension is unramified, so it suffices to count the ground field $k$, which we do by degrees over $Q_3$. In degree 1 there is one case. In degree 2 there are $\phi$ epimorphisms all together. Dividing by the number of automorphisms, we give $[Q_3^x/Q_3^{x^2}] - 1 = 3$ quadratic extensions. Since the abelianization of $G_{Q_3}$ is $C_3^2$, there are $2^3 = 4$ Galois cubic extensions of $Q_3$. For every non-Galois cubic extension $k$ there is a unique $S_3$-Galois extension of $Q_3$ (generated over $k$ by the square root of the discriminant). The $S_3$-Galois extensions of $Q_3$ are in one-to-one correspondence to the normal subgroups of $G_{Q_3}$ with quotient $S_3$. The number of such subgroups is the number of epimorphisms from $G_{Q_3}$ to $S_3$, divided by $|\text{Aut}(S_3)| = 6$. When counting epimorphisms $\phi : G_{Q_3} \to S_3$, we may assume the generators are in $S_3$, which simplifies the presentation a great deal. Since $p^* = q = 3$ and we may assume $g = 1$ and $h = -1$, the presentation is

$$G_{Q_3} = \langle \sigma, (\tau) \rangle, (x_0, x_1) \rangle \mid \tau^3 = x_0^3 = (x_0 \tau x_0^{-1})^2 x_1^3[x_1, y_1] \rangle.$$ 

However, since $x_1$ is a pro-3 element, we may assume $x_1^3 = 1$. Since all elements of order 3 in $S_3$ commute with each other, we may assume $[x_1, y_1] = 1$ (see Theorem 2.19 for more details on $y_1$). Since $\tau$ is a pro-$3'$ element, $\varphi(\tau)$ has order at most 2, so $\varphi(x_0 \tau x_0^{-1})$ is a commutator, whose order must divide 3. Exponentiation by $\frac{3}{2}$ squares such elements. So every epimorphism to $S_3$ splits through

$$\langle \sigma, (\tau) \varphi, (x_0, x_1) \rangle \mid \tau^2 = x_0^3 = x_1^3 = 1, \tau^3 = x_0^3 = (x_0 \tau x_0^{-1})^2,$$

and we count epimorphisms from this group. If $\varphi(\tau) = 1$ then $\varphi(x_0) = 1$, so $\varphi(x_1)$ is a non-trivial element of order 3 and $\varphi(\sigma) \not\in \{\varphi(x_1)\}$. There are 6 such epimorphisms. So assume $\varphi(\tau)$ is a non-trivial involution. The relations give $[\varphi(\sigma), \varphi(\tau)] = 1$, so $\varphi(\sigma)$ is either 1 or $\varphi(\tau)$. Moreover, it turns out that $\varphi(x_0 \tau x_0^{-1} \tau^2 = \varphi(x_0)$ whenever $\varphi(x_0)$ has order dividing 3. For each possible value of $\varphi(\tau)$ we get 8 epimorphisms with $\varphi(\sigma) = 1$ and 2 more with $\varphi(\sigma) = \varphi(\tau)$. There are 3 involutions, providing us with $6 + 3 \cdot 10 = 36$ epimorphisms all together. Dividing by the number of automorphisms, we have 6 Galois extensions of $Q_3$ with Galois group $S_3$. Each Galois extension of this type contains 3 non-Galois cubic extensions of $Q_3$. The $S_3$-extension is determined by the cubic extension, being its Galois closure. So we have $3 \cdot 6 = 18$ non-Galois cubic subfields of a fixed algebraic closure $Q_3$, consisting of 6 isomorphism classes. Summing up, there are $1 + 1 + (1 + 3 + (4 + 6)) + 1 = 17$ sensitive field extensions, up to isomorphism.

Communicated by Ulf Rehmann

Abstract.

Introduction.

Let $k$ be a global field of characteristic $\neq 2$. The classical Hasse–Minkowski theorem states that if two quadratic forms become isomorphic over all the completions of $k$, then they are isomorphic over $k$ as well. It is natural to ask whether this is true for $G$–quadratic forms, where $G$ is a finite group. In the case of number fields the Hasse principle for $G$–quadratic forms does not hold in general, as shown by J. Morales [M 86]. The aim of the present paper is to study this question when $k$ is a global field of positive characteristic. We give a sufficient criterion for the Hasse principle to hold (see th. 2.1.), and also give counter–examples. These counter–examples are of a different nature than those for number fields: indeed, if $k$ is a global field of positive characteristic, then the Hasse principle does hold for $G$–quadratic forms on projective $k[G]$–modules (see cor. 2.3), and in particular if $k[G]$ is semi–simple, then the Hasse principle is true for $G$–quadratic forms, contrarily to what happens in the case of number fields. On the other hand, there are counter–examples in the non semi–simple case, as shown in §3. Note that the Hasse principle holds in all generality for $G$–trace forms (cf. [BPS 13]).

The third named author is partially supported by National Science Foundation grant DMS-1001872.

§1. Definitions, notation and basic facts

Let $k$ be a field of characteristic $\neq 2$. All modules are supposed to be left modules.
Let $G$ be a finite group, and let $k[G]$ be the associated group ring. A $G$–quadratic space is a pair $(V, q)$, where $V$ is a $k[G]$–module that is a finite dimensional $k$–vector space, and $q : V \times V \to k$ is a non–degenerate symmetric bilinear form such that
\[ q(gx, gy) = q(x, y) \]
for all $x, y \in V$ and all $g \in G$.

Two $G$–quadratic spaces $(V, q)$ and $(V', q')$ are isomorphic if there exists an isomorphism of $k[G]$–modules $f : V \to V'$ such that $q'(f(x), f(y)) = q(x, y)$ for all $x, y \in V$. If this is the case, we write $(V, q) \cong_G (V', q')$, or simply $q \cong q'$.

**Hermitian forms**

Let $R$ be a ring endowed with an involution $r \mapsto \sigma(r)$. For any $R$–module $M$, we denote by $M^*$ its dual $\text{Hom}_R(M, R)$. Then $M^*$ has an $R$–module structure given by $(rf)(x) = f(x)\sigma(r)$ for all $r \in R$, $x \in M$ and $f \in M^*$. If $M$ and $N$ are two $R$–modules and if $f : M \to N$ is a homomorphism of $R$–modules, then $f$ induces a homomorphism $f^* : N^* \to M^*$ defined by $f^*(g) = gf$ for all $g \in N^*$, called the adjoint of $f$.

A hermitian form is a pair $(M, h)$ where $M$ is an $R$–module and $h : M \times M \to R$ is biadditive, satisfying the following two conditions:

1. $h(rx, sy) = rh(x, y)\sigma(r)$ and $h(x, y) = h(y, x)$ for all $x, y \in M$ and all $r, s \in R$.
2. The homomorphism $h : M \to M^*$ given by $y \mapsto h(\cdot, y)$ is an isomorphism.

Note that the existence of $h$ implies that $M$ is self-dual, i.e. isomorphic to its dual.

If $G$ is a finite group, then the group algebra $R = k[G]$ has a natural $k$–linear involution, characterized by the formula $\overline{g} = g^{-1}$ for every $g \in G$. We have the following dictionary (see for instance [BPS 13, 2.1, Example])

a) $R$–module $M \iff k$–module $M$ with a $k$–linear action of $G$;

b) $R$–dual $M^* \iff k$–dual of $M$, with the contragredient (i.e. dual) action of $G$.

c) hermitian space $(M, h) \iff$ symmetric bilinear form on $M$, which is $G$–invariant and defines an isomorphism of $M$ onto its $k$–dual.

Therefore a hermitian space over $k[G]$ corresponds to a $G$–quadratic space, as defined above.

**Hermitian elements**

Let $E$ be a ring with an involution $\sigma : E \to E$ and put
\[ E^0 = \{ z \in E^\times \mid \sigma(z) = z \}. \]
If \( z \in E^0 \), the map \( h_z : E \times E \to E \) defined by \( h_z(x,y) = x.z.\sigma(y) \) is a hermitian space over \( E \); conversely, every hermitian space over \( E \) with underlying module \( E \) is isomorphic to \( h_z \) for some \( z \in E^0 \).

Define an equivalence relation on \( E^0 \) by setting \( z \equiv z' \) if there exists \( e \in E^\times \) with \( z' = \sigma(e)ze \); this is equivalent to \((E,h_z) \simeq (E,h_{z'})\). Let \( H(E,\sigma) \) be the quotient of \( E^0 \) by this equivalence relation. If \( z \in E^0 \), we denote by \([z]\) its class in \( H(E,\sigma)\).

**Classifying hermitian spaces via hermitian elements**

Let \((M,h_0)\) be a hermitian space over \( R \). Set \( E_M = \text{End}(M) \). Let \( \tau : E_M \to E_M \) be the involution of \( E_M \) induced by \( h_0 \), i.e.

\[
\tau(e) = h_0^{-1} e^* h_0, \quad \text{for } e \in E_M,
\]

where \( e^* \) is the adjoint of \( e \). If \((M,h)\) is a hermitian space (with the same underlying module \( M \)), we have \( \tau(h_0^{-1}h) = h_0^{-1}(h_0^{-1}h)^* h_0 = h_0^{-1}h^* (h_0^{-1})^* h_0 = h_0^{-1}h \). Hence \( h_0^{-1}h \) is a hermitian element of \((E_M,\tau)\); let \([h_0^{-1}h]\) be its class in \( H(E_M,\tau)\).

**Lemma 1.1.** (see for instance [BPS 13, lemma 3.8.1]) Sending a hermitian space \((M,h)\) to the element \([h_0^{-1}h]\) of \( H(E_M,\tau) \) induces a bijection between the set of isomorphism classes of hermitian spaces \((M,h)\) and the set \( H(E_M,\tau) \).

**Components of algebras with involution**

Let \( A \) be a finite dimensional \( k \)-algebra, and let \( \iota : A \to A \) be a \( k \)-linear involution. Let \( R_A \) be the radical of \( A \). Then \( A/R_A \) is a semi-simple \( k \)-algebra, hence we have a decomposition \( A/R_A = \prod_{i=1}^e M_{n_i}(D_i) \), where \( D_1,\ldots,D_e \) are division algebras. Let us denote by \( K_i \) the center of \( D_i \), and let \( D_i^{op} \) be the opposite algebra of \( D_i \).

Note that \( \iota(R_A) = R_A \), hence \( \iota \) induces an involution \( \iota : A/R_A \to A/R_A \). Therefore \( A/R_A \) decomposes into a product of involution invariant factors. These can be of two types : either an involution invariant matrix algebra \( M_{n_i}(D_i) \), or a product \( M_{n_i}(D_i) \times M_{n_i}(D_i^{op}) \), with \( M_{n_i}(D_i) \) and \( M_{n_i}(D_i^{op}) \) exchanged by the involution. We say that a factor is unitary if the restriction of the involution to its center is the not the identity : in other words, either an involution invariant \( M_{n_i}(D_i) \) with \( \iota|K_i \neq \text{the identity} \), or a product \( M_{n_i}(D_i) \times M_{n_i}(D_i^{op}) \). Otherwise, the factor is said to be of the first kind. In this case, the component is of the form \( M_{n_i}(D_i) \) and the restriction of \( \iota \) to \( K_i \) is the identity. We say that the component is orthogonal if after base change to a separable closure \( \iota \) is given by the transposition, and symplectic otherwise. A component \( M_{n_i}(D_i) \) is said to be split if \( D_i \) is a commutative field.

**Completions**
If $k$ is a global field and if $v$ is a place of $k$, we denote by $k_v$ the completion of $k$ at $v$. For any $k$–algebra $E$, set $E_v = E \otimes_k k_v$. If $K/k$ is a field extension of finite degree and if $w$ is a place of $K$ above $v$, then we use the notation $w/v$.

§2. Hasse principle

In this section, $k$ will be a global field of characteristic $\neq 2$. Let us denote by $\Sigma_k$ the set of all places of $k$. The aim of this section is to give a sufficient criterion for the Hasse principle for $G$–quadratic forms to hold. All modules are left modules, and finite dimensional $k$–vector spaces.

Theorem 2.1. Let $V$ be a $k[G]$–module, and let $E = \text{End}(V)$. Let $R_E$ be the radical of $E$, and set $\overline{E} = E/R_E$. Suppose that all the orthogonal components of $\overline{E}$ are split, and let $(V, q), (V, q')$ be two $G$–forms. Then $q \simeq_G q'$ over $k$ if and only if $q \simeq_G q'$ over all the completions of $k$.

This is announced in [BP 13], and replaces th. 3.5 of [BP 11]. The proof of th. 2.1 relies on the following proposition

Proposition 2.2. Let $E$ be a finite dimensional $k$–algebra endowed with a $k$–linear involution $\sigma : E \to E$. Let $R_E$ be the radical of $E$, and set $\overline{E} = E/R_E$. Suppose that all the orthogonal components of $\overline{E}$ are split. Then the canonical map $H(E, \sigma) \to \prod_{v \in \Sigma_k} H(E_v, \sigma_v)$ is injective.

Proof. The case of a simple algebra. Suppose first that $E$ is a simple $k$–algebra. Let $K$ be the center of $E$, and let $F$ be the fixed field of $\sigma$ in $K$. Let $\Sigma_F$ denote the set of all places of $F$. For all $v \in \Sigma_k$, set $E_v = E \otimes_k k_v$, and note that $E_v = \prod_{w|v} E_w$, therefore $\prod_{v \in \Sigma_k} H(E_v, \sigma_v) = \prod_{w \in \Sigma_F} H(E_w, \sigma_w)$. By definition, $H(E, \sigma)$ is the set of isomorphism classes of one dimensional hermitian forms over $E$. Moreover, if $\sigma$ is orthogonal, then the hypothesis implies that $E$ is split, in other words we have $E \simeq M_n(F)$. Therefore the conditions of [R 11, th. 3.3.1] are fulfilled, hence the Hasse principle holds for hermitian forms over $E$ with respect to $\sigma$. This implies that the canonical map $H(E, \sigma) \to \prod_{v \in \Sigma_k} H(E_v, \sigma_v)$ is injective.

The case of a semi–simple algebra. Suppose now that $E$ is semi–simple. Then

$$E \simeq E_1 \times \ldots \times E_r \times A \times A^{\text{opp}},$$

where $E_1, \ldots, E_r$ are simple algebras which are stable under the involution $\sigma$, and where the restriction of $\sigma$ to $A \times A^{\text{opp}}$ exchanges the two factors. Applying [BPS 13, lemmas 3.7.1 and 3.7.2] we are reduced to the case where $E$ is a simple algebra, and we already know that the result is true in this case.

Documenta Mathematica 18 (2013) 383–392
General case. We have $\overline{E} = E/R_E$. Then $\overline{E}$ is semi–simple, and $\sigma$ induces a $k$–linear involution $\overline{\sigma}: \overline{E} \to \overline{E}$. We have the following commutative diagram

\[
\begin{array}{ccc}
H(E,\sigma) & \xrightarrow{f} & \prod_{v \in \Sigma_k} H(E_v,\sigma) \\
\downarrow & & \downarrow \\
H(E,\overline{\sigma}) & \xrightarrow{\overline{f}} & \prod_{v \in \Sigma_k} H(E_v,\overline{\sigma}),
\end{array}
\]

where the vertical maps are induced by the projection $E \to \overline{E}$. By [BPS 13, lemma 3.7.3], these maps are bijective. As $\overline{E}$ is semi–simple, the map $\overline{f}$ is injective, hence $f$ is also injective. This concludes the proof.

**Proof of th. 2.1.** It is clear that if $q \simeq_G q'$ over $k$, then $q \simeq_G q'$ over all the completions of $k$. Let us prove the converse. Let $(V, h)$ be the $k[G]$–hermitian space corresponding to $(V, q)$, and let $\sigma : E \to E$ be the involution induced by $(V, h)$ as in §1. Let $(V, h')$ be the $k[G]$–hermitian space corresponding to $(V, q')$, and set $u = h^{-1}h'$. Then $u \in E^p$, and by lemma 1.1, the element $[u] \in H(E, \sigma)$ determines the isomorphism class of $(V, q')$; in other words, we have $q \simeq_G q'$ if and only if $[u] = [1]$ in $H(E, \sigma)$. Hence the theorem is a consequence of proposition 2.2.

**Corollary 2.3** Suppose that $\text{char}(k) = p > 0$, and let $V$ be a projective $k[G]$–module. Let $(V, q)$, $(V, q')$ be two $G$–forms. Then $q \simeq_G q'$ over $k$ if and only if $q \simeq_G q'$ over all the completions of $k$.

**Proof.** Since $V$ is projective, there exists a $k[G]$–module $W$ and $n \in N$ such that $V \oplus W \simeq k[G]^n$. The endomorphism ring of $k[G]^n$ is $M_n(k[G])$, and as $\text{char}(k) = p > 0$, we have $k[G] = F_p[G] \otimes_{F_p} k$. Hence $M_n(k[G])$ is isomorphic to $M_n(F_p[G]) \otimes_{F_p} k$. Let $E = \text{End}(V)$, let $R_E$ be the radical of $E$, and let $\overline{E} = E/R_E$. Let us show that all the components of $\overline{E}$ are split. Let $e$ be the idempotent endomorphism of $V \oplus W$ which is the identity of $V$. Set $\Lambda = \text{End}(V \oplus W)$ and let $R_\Lambda$ be the radical of $\Lambda$. Then $eR_\Lambda e = E$ and $eR_\Lambda e = R_E$. Set $\overline{\Lambda} = \Lambda/R_\Lambda$, and and let $\overline{\sigma}$ be the image of $e$ in $\overline{\Lambda}$. Set $k[\overline{\Gamma}] = k[G]/(\text{rad}(k[G])$. Then we have $\overline{E} \cong \overline{\sigma}\overline{\Lambda}\overline{\sigma} \cong \overline{\Lambda} M_n(k[\overline{\Gamma}]) \overline{\sigma}$. This implies that $\overline{E}$ is a component of the semi–simple algebra $M_n(k[\overline{\Gamma}])$. Let us show that all the components of $M_n(k[\overline{\Gamma}])$ are split. As $F_p$ is a finite field, $F_p[G]/(\text{rad}(F_p[G]))$ is a product of matrix algebras over finite fields. Moreover, for any finite field $F$ of characteristic $p$, the tensor product $F \otimes_{F_p} k$ is a product of fields. This shows that $(F_p[G]/(\text{rad}(F_p[G]))) \otimes_{F_p} k$ is a product of matrix algebras over finite extensions of $k$; in particular, it is semi–simple. The natural isomorphism $F_p[G] \otimes_{F_p} k \to k[G]$ induces an isomorphism $[F_p[G]/(\text{rad}(F_p[G]))] \otimes_{F_p} k \to k[G]/(\text{rad}(F_p[G]), k[G])$. Therefore $\text{rad}(F_p[G], k[G])$ is the radical of $k[G]$, and we have an isomorphism $[F_p[G]/(\text{rad}(F_p[G]))] \otimes_{F_p} k \to k[G]/(\text{rad}(k[G]))$. Hence all the components of $k[G]/(\text{rad}(k[G]))$ are split. This implies that all the components of $\overline{E}$ are split as well. Therefore the corollary follows from th. 2.1.

The following corollary is well–known (see for instance [R 11, 3.3.1 (b)]).
Corollary 2.4 Suppose that $\text{char}(k) = p > 0$, and that the order of $G$ is prime to $p$. Then two $G$–quadratic forms are isomorphic over $k$ if and only if they become isomorphic over all the completions of $k$.

Proof. This follows immediately from cor. 2.3.

§3. Counter–examples to the Hasse principle

Let $k$ be a field of characteristic $p > 0$, let $C_p$ be the cyclic group of order $p$, and let $G = C_p \times C_p \times C_p$. In this section we give counter–examples to the Hasse principle for $G \times G$–quadratic forms over $k$ in the case where $k$ is a global field. We start with some constructions that are valid for any field of positive characteristic.

3.1 A construction

Let $D$ be a division algebra over $k$. It is well–known that there exist indecomposable $k[G]$–modules such that their endomorphism ring modulo the radical is isomorphic to $D$. We recall here such a construction, brought to our attention by R. Guralnick, in order to use it in 3.2 in the case of quaternion algebras.

The algebra $D$ can be generated by two elements (see for instance [J 64, Chapter VII, §12, th. 3, p. 182]). Let us choose $i, j \in D$ be two such elements. Let us denote by $D^{op}$ the opposite algebra of $D$, and let $d$ be the degree of $D$. Then we have $D \otimes_k D^{op} \simeq M_d(k)$. Let us choose an isomorphism $f : D \otimes_k D^{op} \simeq M_d(k)$, and set $a_1 = f(1 \otimes 1) = 1$, $a_2 = f(i \otimes 1)$ and $a_3 = f(j \otimes 1)$.

Let $g_1, g_2, g_3 \in G$ be three elements of order $p$ such that the set $\{g_1, g_2, g_3\}$ generates $G$, and let us define a representation $G \to \text{GL}_{2d^2}(k)$ by sending $g_m$ to the matrix

$$
\begin{pmatrix}
I & a_m \\
0 & I
\end{pmatrix}
$$

for all $m = 1, 2, 3$. Note that this is well–defined because $\text{char}(k) = p$. This endows $k^{2d^2}$ with a structure of $k[G]$–module. Let us denote by $N$ this $k[G]$–module, and let $E_N$ be its endomorphism ring. Then

$$
E_N = \left\{ \begin{pmatrix} x & y \\ 0 & x \end{pmatrix} \mid x \in D^{op} \subset M_{d^2}(k), \; y \in M_{d^2}(k) \right\},
$$

and its radical is

$$
R_N = \left\{ \begin{pmatrix} 0 & y \\ 0 & 0 \end{pmatrix} \mid y \in M_{d^2}(k) \right\},
$$

hence $E_N/R_N \simeq D^{op}$. 

Documenta Mathematica 18 (2013) 383–392
3.2. The case of a quaternion algebra

Let $H$ be a quaternion algebra over $k$. Then by 3.1, we get a $k[G]$-module $N = NH$ with endomorphism ring $E_N$ such that $E_N/R_N \simeq H^{op}$, where $R_N$ is the radical of $E_N$. We now construct a $G$-quadratic form $q$ over $N$ in such a way that the involution it induces on $E_N/R_N \simeq H^{op}$ is the canonical involution.

Let $i, j \in H$ such that $i^2, j^2 \in k^\times$ and that $ij = -ji$. Let $\tau : H \to H$ be the orthogonal involution of $H$ obtained by composing the canonical involution of $H$ with $\text{Int}(ij).$ Let $\sigma : H^{op} \to H^{op}$ be the canonical involution of $H^{op}$. Let us consider the tensor product of algebras with involution

$$(H, \tau) \otimes (H^{op}, \sigma) = (M_4(k), \rho).$$

Then $\rho$ is a symplectic involution of $M_4(k)$ satisfying $\rho(a_m) = a_m$ for all $m = 1, 2, 3$, since $\tau(i) = (ij)(-i)(ij)^{-1} = i$, $\tau(j) = (ij)(-j)(ij)^{-1} = j$. Let $\alpha \in M_4(k)$ be a skew-symmetric matrix such that for all $x \in M_4(k)$, we have

$$\rho(x) = \alpha^{-1}x^T \alpha,$$

where $x^T$ denotes the transpose of $x$. Set $A = \begin{pmatrix} 0 & \alpha \\ -\alpha & 0 \end{pmatrix}$.

Then $A^T = A$. Let $q : N \times N \to k$ be the symmetric bilinear form defined by $A$:

$$q(v, w) = v^T Aw$$

for all $v, w \in N$. Let $\gamma : M_8(k) \to M_8(k)$ be the involution adjoint to $q$, that is

$$\gamma(X) = A^{-1}X^T A$$

for all $X \in M_8(k)$, i.e. $q(fv, w) = q(v, \gamma(f)w)$ for all $f \in M_8(k)$ and all $v, w \in N$. The involution $\gamma$ restricts to an involution of $E_N$, as for all $x, y \in M_4(k)$, we have

$$\gamma \begin{pmatrix} x & y \\ 0 & x \end{pmatrix} = \begin{pmatrix} \alpha^{-1}x^T \alpha & -\alpha^{-1}y^T \alpha \\ 0 & \alpha^{-1}x^T \alpha \end{pmatrix}.$$

It also sends $R_N$ to itself, and induces an involution $\overline{\gamma}$ on $H^{op} \simeq E_N/R_N$ that coincides with the canonical involution of $H^{op}$.

We claim that $q : N \times N \to k$ is a $G$-quadratic form. To check this, it suffices to show that $q(g_m v, g_m w) = q(v, w)$ for all $v, w \in N$ and for all $m = 1, 2, 3$. Since $\rho(a_m) = a_m$ for all $m = 1, 2, 3$, we have

$$\gamma \begin{pmatrix} I & a_m \\ 0 & I \end{pmatrix} = \begin{pmatrix} I & a_m \\ 0 & I \end{pmatrix}^{-1}$$

and hence

$$q(g_m v, g_m w) = q(v, \gamma(g_m)g_m w) = q(v, w)$$

for all $m = 1, 2, 3$ and all $v, w \in N$. Thus $q$ is a $G$-quadratic form, and by construction, the involution of $E_N$ induced by $q$ is the restriction of $\gamma$ to $E_N$. 

Documenta Mathematica 18 (2013) 383–392
3.3. Two quaternion algebras

Let \( H_1 \) and \( H_2 \) be two quaternion algebras over \( k \). By the construction of 3.2, we obtain two indecomposable \( k[G] \)-modules \( N_1 \) and \( N_2 \). Set \( E_1 = E_{N_1} \) and \( E_2 = E_{N_2} \). Let \( R_i \) be the radical of \( E_i \) for \( i = 1, 2 \), and set \( \overline{E}_i = E_i/R_i \). We also obtain \( G \)-quadratic spaces \( q_i : N_i \times N_i \to k \) inducing involutions \( \gamma_i : E_i \to E_i \) such that the involutions \( \overline{\gamma}_i : \overline{E}_i \to \overline{E}_i \) coincide with the canonical involution of \( H_{i, op} \), for all \( i = 1, 2 \).

Let us consider the tensor product \( (N, q) = (N_1, q_1) \otimes_k (N_2, q_2) \). Then \( (N, q) \) is a \( G \times G \)-quadratic space. Set \( E = \text{End}_{k[G \times G]}(N_1 \otimes N_2) \). Then \( E \simeq E_1 \otimes E_2 \). Let \( I \) be the ideal of \( E \) generated by \( R_1 \) and \( R_2 \). Then there is a natural isomorphism \( f : E_1 \otimes E_2 \to E \) with \( f(I) = R_E \), where \( R_E \) is the radical of \( E \). Set \( \overline{E} = E/R_E \). Then \( \overline{E} \simeq \overline{E}_1 \otimes \overline{E}_2 \simeq H_{1, op} \otimes H_{2, op} \).

Set \( \gamma = \gamma_1 \otimes \gamma_2 \). Then \( \gamma : E \to E \) is the involution induced by the \( G \times G \)-quadratic space \((N, q)\). We obtain an involution \( \overline{\gamma} : \overline{E} \to \overline{E} \), and \( \overline{\gamma} = \overline{\gamma}_1 \otimes \overline{\gamma}_2 \).

Let us recall that \( \overline{E}_i = H_{i, op} \) for \( i = 1, 2 \), and that \( \overline{\gamma}_i \) is the canonical involution of \( H_{i, op} \). Hence \( \overline{\gamma} : \overline{E} \to \overline{E} \) is an orthogonal involution.

3.4. A counter-example to the Hasse principle

Suppose now that \( k \) is a global field of characteristic \( p \), with \( p > 2 \), and suppose that \( H_i \) is ramified at exactly two places \( v_1, v'_1 \) of \( k \), such that \( v_1, v'_1, v_2, v'_2 \) are all distinct. We have \( H_{1, op} \otimes H_{2, op} \simeq M_2(Q) \) where \( Q \) is a quaternion division algebra over \( k \), and \( Q \) is ramified exactly at the places \( v_1, v'_1, v_2, v'_2 \) of \( k \). Recall that the involution \( \overline{\gamma} : M_2(Q) \to M_2(Q) \) is the tensor product of the canonical involutions of \( H_{i, op} \). In particular, \( \overline{\gamma} \) is of orthogonal type. Note that at all \( v \in \Sigma_k \), one of the algebras \( H_{1, op} \) or \( H_{2, op} \) is split. This implies that at all \( v \in \Sigma_k \), the involution \( \overline{\gamma} \) is hyperbolic.

Let \( \delta : Q \to Q \) be an orthogonal involution of the division algebra \( Q \). Then \( \overline{\gamma} \) is induced by some hermitian space \( h : Q^2 \times Q^2 \to Q \) with respect to the involution \( \delta \). As for all \( v \in \Sigma_k \), the involution \( \overline{\gamma} \) is hyperbolic at \( v \), the hermitian form \( h \) is also hyperbolic at \( v \). By Lemma 1.1 the set of isomorphism classes of hermitian spaces on \( Q^2 \) is in bijection with the set \( H(\overline{E}, \overline{\gamma}) \), the hermitian space \((Q^2, h)\) corresponding to the element \([1] \in H(\overline{E}, \overline{\gamma})\).

Let \((Q^2, h')\) be a hermitian space which becomes isomorphic to \((Q^2, h)\) over \( Q_v \), for all \( v \in \Sigma_k \), but is not isomorphic to \((Q^2, h)\) over \( Q \) (this is possible by [Sch 85, 10.4.6]). Let \( u \in \overline{E} \), such that \([u] \in H(\overline{E}, \overline{\gamma})\) corresponds to \((Q^2, h')\) by the bijection of lemma 1.1. Then \([u] \neq [1] \in H(\overline{E}, \overline{\gamma})\), and the images of \([u] \) and \([1] \) coincide in \( \prod_{v \in \Sigma_k} H(\overline{E}_v, \overline{\gamma}) \).

Recall that \( H(E, \gamma) \) is in bijection with the isomorphism classes of \((G \times G)\)-quadratic forms over \( N \), the element \([1] \in H(E, \gamma) \) corresponding to the isomorphism class of \((N, q)\). Let \( \pi : E \to \overline{E} \) be the projection, and let \( \tilde{u} \in E^0 \) be...
such that $\pi(\tilde{u}) = u$ (cf. lemma 1.1). Let $(N, q')$ be a $(G \times G)$–quadratic form corresponding to $\tilde{u}$. The diagram

$$
\begin{align*}
H(E, \gamma) & \xrightarrow{f} \prod_{v \in \Sigma_k} H(E_v, \gamma) \\
\downarrow & \downarrow \\
H(E', \tau) & \xrightarrow{f'} \prod_{v \in \Sigma_k} H(E'_v, \tau),
\end{align*}
$$

is commutative, and the vertical maps are bijective by [BPS 13, lemma 3.7.3]. Hence $(N, q)$ and $(N, q')$ are become isomorphic over all the completions of $k$, but are not isomorphic over $k$.

E. BAYER–FLUCKIGER AND R. PARIMALA

Revised: February 17, 2013
Communicated by Ulf Rehmann

Theorem 3.5 of [BP 11] is not correct as stated, and should be replaced by

THEOREM. Let $V$ be a $k[G]$–module that is a finite dimensional $k$–vector space, and let $E = \text{End}(V)$. Let $R_E$ be the radical of $E$, and set $\overline{E} = E/R_E$. Suppose that all the orthogonal components of $\overline{E}$ are split, and let $(V, q), (V, q')$ be two $G$–forms. Then $q \simeq_G q'$ over $k$ if and only if $q \simeq_G q'$ over all the completions of $k$.

This is proved in [BPN 13], Theorem 2.1. Note however that very few changes are needed in [BP 11]. Indeed, Theorem 3.5 and its proof are correct when $k[G]$ is semi–simple, and this is the only case that is used in the sequel of [BP 11].

On Zagier’s Conjecture for Base Changes of Elliptic Curves

François Brunault

Received: June 15, 2012
Revised: December 21, 2012

Communicated by Stephen Lichtenbaum

Abstract. Let $E$ be an elliptic curve over $\mathbb{Q}$, and let $F$ be a finite abelian extension of $\mathbb{Q}$. Using Beilinson’s theorem on a suitable modular curve, we prove a weak version of Zagier’s conjecture for $L(E_F, 2)$, where $E_F$ is the base change of $E$ to $F$.

2010 Mathematics Subject Classification: 11G40, 11G55, 19F27

Keywords and Phrases: Elliptic curves, $L$-functions, elliptic dilogarithm, Zagier’s conjecture, regulators, Beilinson’s conjecture

Introduction

Zagier conjectured in [19] very deep relations between special values of zeta functions at integers, special values of polylogarithms at algebraic arguments and $K$-theory. While the original conjectures concerned the Dedekind zeta function of a number field and Artin $L$-functions, theoretical and numerical results by many authors suggested an extension of these conjectures to elliptic curves (see [20] for an historical account). A precise formulation for elliptic curves over number fields was given by Wildeshaus in [17]. The conjecture on $L(E, 2)$, where $E$ is an elliptic curve over $\mathbb{Q}$, was proved by Goncharov and Levin in [11]. In this article, we prove an analogue of Goncharov and Levin’s result for the base change of $E$ to an arbitrary abelian number field.

Let $E$ be an elliptic curve defined over $\mathbb{Q}$. Let $F \subset \overline{\mathbb{Q}}$ be a finite abelian extension of $\mathbb{Q}$, and let $E_F$ be the base change of $E$ to $F$. The $L$-function $L(E_F, s)$ admits a factorization $\prod_{\chi \in \hat{G}} L(E \otimes \chi, s)$, where $\hat{G}$ is the group of $\overline{\mathbb{Q}}^*$-valued characters of $G = \text{Gal}(F/\mathbb{Q})$. Each factor $L(E \otimes \chi, s)$ has an analytic continuation to $\mathbb{C}$ with a simple zero at $s = 0$. The functional equation relates $L(E_F, 2)$ with the leading term of $L(E_F, s)$ at $s = 0$. 
Let $D_E$ (resp. $J_E$) be the Bloch elliptic dilogarithm (resp. its “imaginary” cousin) on $E(C) \cong C/(Z + \tau Z)$ (see [28] for the definitions). These functions induce linear maps on the free abelian group $\mathbb{Z}[E(C)]$, and thus on $\mathbb{Z}[E(\overline{Q})]$ after fixing an embedding $\iota : \overline{Q} \to C$. Let $\mathbb{Z}[E(\overline{Q})]^{G_F}$ denote the subgroup of divisors fixed by $G_F := \text{Gal}(\overline{Q}/F)$. It carries a natural action of $G$. The main theorem of this article can be stated as follows.

**Theorem 1.** There exists a divisor $\ell \in \mathbb{Z}[E(\overline{Q})]^{G_F}$ such that for every character $\chi \in \hat{G}$, the following identity holds

$$L'(E \otimes \chi, 0) \sim \chi \left\{ \begin{array}{ll} \frac{1}{\pi} \sum_{\sigma \in G} \chi(\sigma) D_E(\ell^\sigma) & \text{if $\chi$ is even}, \\ \frac{1}{\pi(\tau)} \sum_{\sigma \in G} \chi(\sigma) J_E(\ell^\sigma) & \text{if $\chi$ is odd}. \end{array} \right. \quad (1)$$

Using the Dedekind-Frobenius formula for group determinants, we deduce from Theorem 1 the following result. Let us denote the elements of $G$ by $\sigma_1, \ldots, \sigma_d$ (resp. $\sigma_1, \overline{\sigma_1}, \ldots, \sigma_d, \overline{\sigma_d}$) if $F$ is real (resp. complex), with $d = [F : \mathbb{Q}]$.

**Corollary (Weak version of Zagier’s conjecture for $L(E_F, 2)$).**

Let $\ell \in \mathbb{Z}[E(\overline{Q})]^{G_F}$ be a divisor satisfying the identities (1) of Theorem 1. For any $i$, define $\ell_i = \ell^{\sigma_i}$. If $F$ is real, then we have

$$L(E_F, 2) \sim \chi \pi^d \cdot \det(D_E(\ell_i^{\sigma_i}))_{1 \leq i, j \leq d}. \quad (2)$$

If $F$ is complex, then we have

$$L(E_F, 2) \sim \chi \pi^d \left\{ \begin{array}{ll} \frac{1}{\pi(\tau)} \sum_{\sigma \in G} \chi(\sigma) D_E(\ell^\sigma) & \text{if $\chi$ is even}, \\ \frac{1}{\pi(\tau)} \sum_{\sigma \in G} \chi(\sigma) J_E(\ell^\sigma) & \text{if $\chi$ is odd}. \end{array} \right. \quad (3)$$

**Remarks.**

1. Wildeshaus’s formulation of the conjecture [17] Conjecture, Part 2, p. 366] uses Kronecker double series instead of $D_E$ and $J_E$. The link between these objects is classical (see the proof of Prop. 6).

We have chosen to formulate our results in terms of $D_E$ and $J_E$ because these functions are easier to compute numerically and make apparent the distinction according to the parity of $\chi$.

2. Because of the definition of $\ell_i$, the determinant appearing in (2) is a group determinant, indexed by $G$. In fact, the eigenvalues of the matrix $(D_E(\ell_i^{\sigma_i}))$ are precisely the sums $\sum_{\sigma \in G} \chi(\sigma) D_E(\ell^\sigma)$ appearing in Theorem 1. This is an algebraic counterpart of the factorization of the $L$-value of $E_F$ as a product of twisted $L$-values.

3. The divisor $\ell$ produced by Theorem 1 satisfies Goncharov and Levin’s conditions [11] (2)-(4). Following [28], let $A_{E/F} \subset \mathbb{Z}[E(\overline{Q})]^{G_F}$ be the group of divisors satisfying these conditions. The strong version of Zagier’s conjecture predicts that if $F$ is real (resp. complex), then for any divisors $\ell_1, \ldots, \ell_d \in A_{E/F}$ (resp. $\ell_1, \ldots, \ell_d \in A_{E/F}$), the right-hand side of (2) (resp. (3)) is a rational multiple of $L(E_F, 2)$ (possibly equal to zero). As in the case $F = \mathbb{Q}$, this strong conjecture is beyond the reach of current technology.
In order to prove Theorem 1, we prove a weak version of Beilinson’s conjecture for the special value $L^{(d)}(E_F, 0)$ (see [3] for the definition of the objects involved in the following theorem).

**Theorem 2.** There exists a subspace $\mathcal{P}_{E/F} \subset H^2_{\text{mot}}(E_F, \mathbb{Q}(2))$ such that $R_{E/F} := \text{reg}_{E/F}(\mathcal{P}_{E/F})$ is a $\mathbb{Q}$-structure of $H^1(E_F(\mathbb{C}), \mathbb{R})^-$ and

$$\det(R_{E/F}) = L^{(d)}(E_F, 0) \cdot \det(H^1(E_F(\mathbb{C}), \mathbb{Q})^-).$$ (4)

We prove Theorem 2 by using Beilinson’s theorem on a suitable modular curve. More precisely, we make use of a result of Schappacher and Scholl [15] on the (non geometrically connected) modular curve $X_1(N)_F$, where $N$ is the conductor of $E$. We therefore need to work in the adelic setting. We establish a divisibility statement in the Hecke algebra of $X_1(N)_F$ in order to get the desired result for $E_F$.

The methods used in this article are of inexplicit nature and do not give rise, in general, to explicit divisors. However, Theorem 1 and its corollary can be made explicit in the particular case of the elliptic curve $E = X_1(11)$ and the maximal real subfield $F = \mathbb{Q}(\zeta_{11})^+$ inside the cyclotomic field $\mathbb{Q}(\zeta_{11})$. In fact, we may take for $\ell$ a divisor on the cuspidal subgroup of $E$. The tools for proving this are Kato’s explicit version of Beilinson’s theorem for the modular curve $X_1(N)_{\mathbb{Q}(\zeta_m)}$, the work of the author [3], as well as a technique used by Mellit [13] to get new relations between values of the elliptic dilogarithm. We hope to give soon an expanded account of this example.

The organization of the article is as follows. In §1, we recall well-known facts about $L(E_F, s)$. In §2 and §3, we recall the definition of the regulator map and we compute it for $E_F$ (Prop. 9). In §4, we explain the adelic setting for modular curves. In §5, we prove the divisibility we need in the Hecke algebra (Prop. 16). Finally, we give in §6 the proofs of the main results. We conclude with some remarks and a conjecture in the case $F/\mathbb{Q}$ is not abelian.

**Acknowledgements.** I would like to thank Anton Mellit for the very inspiring discussions which led to the discovery of the example alluded to above, which in turn motivated all the results presented here.

1 The $L$-function of the base change

By the Kronecker-Weber theorem, we have $F \subset \mathbb{Q}(\zeta_m)$ for some $m \geq 1$, so that $G$ is a quotient of $(\mathbb{Z}/m\mathbb{Z})^*$ and $\overline{G}$ can be identified with a subgroup of the Dirichlet characters modulo $m$.

Let $f = \sum_{n \geq 1} a_n q^n \in S_2(\Gamma_0(N))$ be the newform associated to $E$. For any $\chi \in \overline{G}$, define $L(E \otimes \chi, s) := L(f \otimes \chi, s)$, where $f \otimes \chi$ is the unique newform of weight 2 whose $p$-th Fourier coefficient is $a_p \chi(p)$ for every prime $p \nmid Nm$. The $L$-function of $E_F$ has the following description.

\[ \text{Documenta Mathematica 18 (2013) 395–412} \]
Proposition 3. The following identity holds:

\[ L(E_F, s) = \prod_{\chi \in \hat{G}} L(f \otimes \chi, s). \]  

(5)

Proof. Let \( \rho = (\rho_\ell) \) be the compatible system of 2-dimensional \( \ell \)-adic representations of \( G_\mathbb{Q} \) attached to \( f \) by Deligne [5]. By modularity \( L(E_F, s) = L(\rho|_{G_F}, s) \). Using Artin’s formalism for \( L \)-functions, we have

\[ L(\rho|_{G_F}, s) = L(\text{Ind}_{G_\mathbb{Q}}^{G_F}(\rho|_{G_F}), s). \]  

(6)

If \( 1_{G_F} \) denotes the trivial representation of \( G_F \), we have

\[ \text{Ind}_{G_\mathbb{Q}}^{G_F}(\rho|_{G_F}) \cong \text{Ind}_{G_\mathbb{Q}}^{G_F}(1_{G_F}) \otimes \rho \]  

(7)

\[ \cong \bigoplus_{\chi \in \hat{G}} \rho \otimes \chi. \]  

(Here we chose embeddings \( \overline{\mathbb{Q}} \to \overline{\mathbb{Q}_\ell} \).) Finally, since an irreducible \( \ell \)-adic representation of \( G_\mathbb{Q} \) is determined by the traces of all but finitely many Frobenius elements, the compatible system associated to \( f \otimes \chi \) is \( \rho \otimes \chi \), so that

\[ L(\rho \otimes \chi, s) = L(f \otimes \chi, s) \]  

for any \( \chi \in \hat{G} \).

Proposition 4. We have

\[ L(E_F, 2) \sim_{\mathbb{Q}^*} \pi^{2d} L^{(d)}(E_F, 0), \]  

where \( L^{(d)}(E_F, 0) \) denotes the \( d \)-th derivative at \( s = 0 \).

Proof. Since each \( L(f \otimes \chi, s) \) has a simple zero at \( s = 0 \), we get

\[ \frac{L^{(d)}(E_F, 0)}{d!} = \prod_{\chi \in \hat{G}} L'(f \otimes \chi, 0), \]  

(8)

Let \( N_{f \otimes \chi} \) be the level of the newform \( f \otimes \chi \). Putting \( \Lambda(f \otimes \chi, s) = N_{f \otimes \chi}^{s/2}(2\pi)^{-s} \Gamma(s)L(f \otimes \chi, s) \), we have [7, §5]

\[ \Lambda(f \otimes \chi, s) = -w_{f \otimes \chi} \Lambda(f \otimes \overline{\chi}, 2 - s) \quad (s \in \mathbb{C}) \]  

(9)

where \( w_{f \otimes \chi} \) is the pseudo-eigenvalue of \( f \otimes \chi \) with respect to the Atkin-Lehner involution of level \( N_{f \otimes \chi} \). Note that [10] implies \( w_{f \otimes \chi} w_{f \otimes \overline{\chi}} = 1 \). Letting \( w = \prod_{\chi \in \hat{G}} w_{f \otimes \chi} \), we have

\[ w^2 = \prod_{\chi \in \hat{G}} w_{f \otimes \chi} w_{f \otimes \overline{\chi}} = 1 \]  

(10)

so that \( w = \pm 1 \). Moreover \( \Lambda(f \otimes \chi, 0) = L'(f \otimes \chi, 0) \) and \( \Lambda(f \otimes \overline{\chi}, 2) = (N_{f \otimes \chi}/4\pi^2)L(f \otimes \overline{\chi}, 2) \). Taking the product over \( \chi \) yields the result. \( \square \)
2. The regulator map on Riemann surfaces

In this section, we recall the definition of the regulator map on compact Riemann surfaces [5, §1], and its computation in the case of elliptic curves. Let $X$ be a compact connected Riemann surface, and $\mathcal{M}(X)$ be its field of meromorphic functions. For any $f, g \in \mathcal{M}(X)^*$, consider the 1-form

$$\eta(f, g) := \log |f| \cdot \text{darg}(g) - \log |g| \cdot \text{darg}(f).$$

(11)

For any $f \in \mathcal{M}(X) \setminus \{0, 1\}$, the differential form $\eta(f, 1 - f)$ is exact on $X \setminus f^{-1}(\{0, 1, \infty\})$. More precisely $\eta(f, 1 - f) = d(D \circ f)$, where $D$ is the Bloch-Wigner dilogarithm function [13]. Let $K_2(\mathcal{M}(X))$ be the Milnor $K_2$-group associated to $\mathcal{M}(X)$. The regulator map on $X$ is the unique linear map

$$\text{reg}_X : K_2(\mathcal{M}(X)) \to H^1(X, \mathbb{R})$$

(12)

such that for any $f, g \in \mathcal{M}(X)^*$ and any holomorphic 1-form $\omega$ on $X$, we have

$$\int_X \text{reg}_X \{f, g\} \wedge \omega = \frac{1}{2\pi} \int_X \eta(f, g) \wedge \omega.$$

(13)

The map $\text{reg}_X$ is well-defined by exactness of $\eta(f, 1 - f)$ and Stokes’ theorem. The construction of $\text{reg}_X$ easily extends to the case where $X$ is compact but not connected. Indeed, put $\mathcal{M}(X) := \prod_{i=1}^r \mathcal{M}(X_i)$ where $X_1, \ldots, X_r$ are the connected components of $X$. Then $K_2(\mathcal{M}(X)) \cong \bigoplus_{i=1}^r K_2(\mathcal{M}(X_i))$ as well as $H^1(X, \mathbb{R}) \cong \bigoplus_i H^1(X_i, \mathbb{R})$, and we define $\text{reg}_X$ to be the direct sum of the maps $\text{reg}_{X_i}$ for $1 \leq i \leq r$.

Let us recall the classical computation of the regulator map on a complex torus [11, §4]. Let $E_\tau := \mathbb{C}/(\mathbb{Z} + \tau \mathbb{Z})$ with $\tau \in \mathbb{C}$, $\text{Im}(\tau) > 0$. The map $z \mapsto \exp(2\pi i z)$ induces an isomorphism $E_\tau \cong \mathbb{C}^*/q^\mathbb{Z}$, where $q := \exp(2\pi i \tau)$. Let $D_q : E_\tau \to \mathbb{R}$ be the Bloch elliptic dilogarithm, defined by $D_q([x]) = \sum_{n=-\infty}^{\infty} D(q^n x)$ for any $x \in \mathbb{C}^\times$. We will also use the function $J_q : E_\tau \to \mathbb{R}$, which is defined as follows. Let $J : \mathbb{C}^* \to \mathbb{R}$ be the function defined by $J(x) = \log |x| \cdot \log |1 - x|$ if $x \neq 1$, and $J(1) = 0$. Following [13], we put

$$J_q([x]) = \sum_{n=0}^{\infty} J(q^n x^n) - \sum_{n=1}^{\infty} J(x^{-1} q^n) + \frac{1}{3} \log^2 |q| \cdot B_3 \left( \frac{|x|}{\log |q|} \right) \quad (x \in \mathbb{C}^*)$$

(14)

where $B_3 = x^3 - \frac{1}{2} x^2 + \frac{1}{12}$ is the third Bernoulli polynomial. The function $J_q$ is well-defined since $J(x) + J(\frac{1}{x}) = \log |x|$ and $B_3(x + 1) - B_3(x) = 3x^2$. Both functions $D_q$ and $J_q$ extend to linear maps $\mathbb{Z}[E_\tau] \to \mathbb{R}$, by setting $D_q(\sum_i n_i[P_i]) := \sum_i n_i D_q(P_i)$ and similarly for $J_q$.

**Definition 5.** For any $f, g \in \mathcal{M}(E_\tau)^*$ with divisors $\text{div}(f) = \sum_i m_i[P_i]$ and $\text{div}(g) = \sum_i n_j[Q_j]$, the divisor $\beta(f, g) \in \mathbb{Z}[E_\tau]$ is defined by

$$\beta(f, g) = \sum_{i,j} m_i n_j [P_i - Q_j].$$

(15)
The following classical result expresses the regulator map on $E_\tau$ in terms of $D_q$ and $J_q$.

**Proposition 6.** For any $f, g \in \mathcal{M}(E_\tau)^\times$, we have

\[
\int_{E_\tau} \eta(f, g) \wedge dz = (D_q - iJ_q)(\beta(f, g)).
\] (16)

**Proof.** We have $\int_{E_\tau} \eta(f, g) \wedge dz = -\frac{2(\tau)^2}{\pi}K_{2,1,\tau}(\beta(f, g))$ by [12 §4.3] and [6 (6.2)], where $K_{2,1,\tau}$ is the linear extension of the following Eisenstein-Kronecker series on $E_\tau$:

\[
K_{2,1,\tau}(z) := \sum_{\lambda \in \mathbb{Z}^+ \tau \mathbb{Z}} \exp\left(\frac{2i\pi}{\lambda}(z^\tau - \bar{z^\tau})\right) / \lambda^2 (z \in \mathbb{C}/(\mathbb{Z}^+ \tau \mathbb{Z})).
\] (17)

The result now follows from the formula $-\frac{2(\tau)^2}{\pi}K_{2,1,\tau} = D_q - iJ_q$, for which we refer to [2, Thm 10.2.1] and [15 §2, p. 616].

3. The Regulator Map on the Base Change

Let $X$ be a connected (but not necessarily geometrically connected) smooth projective curve over $\mathbb{Q}$. Its function field $\mathbb{Q}(X)$ embeds into $\mathcal{M}(X(\mathbb{C}))$, so we get a natural map $K_2(\mathbb{Q}(X)) \to K_2(\mathcal{M}(X(\mathbb{C})))$. Let $c$ denote the complex conjugation on $X(\mathbb{C})$. For any $f, g \in \mathbb{Q}(X)^\times$, we have $c^* \eta(f, g) = -\eta(f, g)$, so that [12] induces a map

\[
K_2(\mathbb{Q}(X)) \to H^3(X(\mathbb{C}), \mathbb{R})^-, \quad (18)
\]

where $(\cdot)^-$ denotes the $(-1)$-eigenspace of $c^*$.

Let $K_2(X)$ be the Quillen algebraic $K_2$-group associated to $X$. Recall that the motivic cohomology group $H^2_M(X, \mathbb{Q}(2)) := K_2^{(2)}(X)$ is defined as the second Adams eigenspace of $K_2(X) \otimes \mathbb{Q}$. The exact localization sequence in $K$-theory yields a canonical injective map $K_2(X) \otimes \mathbb{Q} \to K_2(\mathbb{Q}(X)) \otimes \mathbb{Q}$ which is compatible with the Adams operations, so that in fact $K_2^{(2)}(X) = K_2(X) \otimes \mathbb{Q}$.

The integral subspace $H^2_M(X, \mathbb{Q}(2)) \subset H^2_M(X, \mathbb{Q}(2))$ is the image of the map $K_2(X) \otimes \mathbb{Q} \to K_2(X) \otimes \mathbb{Q}$ for any proper regular model $X/\mathbb{Z}$ of $X$ (see [10] for a definition in a more general setting). Tensoring [15] with $\mathbb{Q}$ and restricting to the integral subspace gives the Beilinson regulator map on $X$:

\[
\text{reg}_X : H^2_M(Z(X, \mathbb{Q}(2))) \to H^1(X(\mathbb{C}), \mathbb{R})^-.
\] (19)

Note that the real vector space $H^1(X(\mathbb{C}), \mathbb{R})^-$ admits the natural $\mathbb{Q}$-structure $H_X := H^1(X(\mathbb{C}), \mathbb{Q})^-$.

Any finite morphism $\varphi : X \to Y$ between smooth projective curves over $\mathbb{Q}$ induces maps $\varphi^* : K_2(Y) \to K_2(X)$ and $\varphi_* : K_2(X) \to K_2(Y)$, the latter being
Let us return to our elliptic curve $E$. Fix an isomorphism $E(\mathbb{C}) \cong E_\tau$ which is compatible with complex conjugation, and let $q = \exp(2i\pi\tau)$. Let $D_E$ and $J_E$ be the real-valued functions on $E(\mathbb{C})$ induced by $D_q$ and $J_q$, respectively. The space $H^1(E(\mathbb{C}), \mathbb{Q})^\ast$ is generated by the 1-form $\eta^\ast$, with

$$\eta^\ast = dz + d\bar{z} \quad \text{and} \quad \eta^- = \frac{dz - d\bar{z}}{\tau - \bar{\tau}}$$

**Lemma 7.** Let $f, g \in \mathbb{C}(E)^\times$ and $\ell = \beta(f, g)$. We have

$$\text{reg}_{E(\mathbb{C})}(f, g) = \frac{1}{2i\pi} (D_E(\ell) \cdot \eta^\ast + J_E(\ell) \cdot \eta^-).$$

**Proof.** Using (13) with Prop. 6 and identifying the real and imaginary parts gives the lemma.

Let $\Sigma$ be the set of embedding of $F$ into $\mathbb{C}$. We consider $E_F = E \times_{\text{Spec} \mathbb{Q}} \text{Spec} F$ as a scheme over $\text{Spec} \mathbb{Q}$, so that $E_F(\mathbb{C})$ is the disjoint union of $d$ copies of $E(\mathbb{C})$. In particular

$$H^1(E_F(\mathbb{C}), \mathbb{R}) \cong \bigoplus_{\psi \in \Sigma} H^1(E(\mathbb{C}), \mathbb{R})$$

and $H^1(E_F(\mathbb{C}), \mathbb{Q})$ decomposes accordingly. The group $G$ acts from the right on $E_F$. This induces a left action of $G$ on $H^1(E_F(\mathbb{C}), \mathbb{Q})$. For any character $\chi \in \widehat{G}$, consider the idempotent

$$e_\chi := \frac{1}{|G|} \sum_{\sigma \in \widehat{G}} \chi(\sigma) \cdot [\sigma] \in \overline{\mathbb{Q}}[G].$$

It acts on $H^1(E_F(\mathbb{C}), \overline{\mathbb{Q}} \otimes \mathbb{R})$. For any $\psi \in \Sigma$, let $\eta^\ast(\psi)$ be the 1-form $\eta^\ast$ sitting in the $\psi$-component of (23). Note that the embedding $\iota : \overline{\mathbb{Q}} \hookrightarrow \mathbb{C}$ induces a distinguished element $\iota \in \Sigma$. Define

$$\eta_\chi = \begin{cases} e_\chi(\eta^-(\iota)) & \text{if } \chi \text{ is even}, \\ e_\chi(\eta^+(\iota)) & \text{if } \chi \text{ is odd}. \end{cases}$$

The lattice $\mathbb{Z} + i\mathbb{Z}$ is uniquely determined by $E$, and $q$ is a well-defined real number such that $0 < |q| < 1$. But the pair $(D_E, J_E)$ is defined only up to sign (choosing an isomorphism $E(\mathbb{C}) \cong E_\tau$ amounts to specifying an orientation of $E(\mathbb{R})$).

---

*Documenta Mathematica* 18 (2013) 395–412
LEMMA 8. If \( c : E_F(C) \to E_F(C) \) is the map induced by complex conjugation on Spec \( C \), then \( c^* \eta_\chi = -\eta_\chi \).

Proof. For any \( \psi \in \Sigma \), we have \( c^* \eta^\chi(\psi) = \pm \eta^\chi(\overline{\psi}) \). It follows that

\[
c^* \eta_\chi = \frac{1}{|G|} \sum_{\sigma \in G} \chi(\sigma) c^* (\sigma \cdot \eta^\chi(\psi)) = -\chi(1) \frac{1}{|G|} \sum_{\sigma \in G} \chi(\sigma) (\overline{\sigma} \cdot \eta^\chi(\psi)).
\]

Since \( \chi(1) \chi(\sigma) = \chi(\overline{\sigma}) \), we get the result. \( \square \)

The map \( \beta \) induces a linear map \( F(E)^\chi \otimes F(E)^\chi \to \mathbb{Z}[E(\overline{\mathbb{Q}})]^{G_\ell} \), which we still denote by \( \beta \). The following proposition computes explicitly the regulator map associated to \( E_\ell \).

PROPOSITION 9. Let \( \gamma \in F(E)^\chi \otimes F(E)^\chi \) and \( \ell = \beta(\gamma) \). For any \( \chi \in \widehat{G} \), we have \( c_\chi \text{reg}_{E/F}(\langle \gamma \rangle) = \mu_\chi(\ell) \cdot \eta_\chi \), where \( \mu_\chi(\ell) \in \mathbb{Q} \otimes \mathbb{R} \) is given by

\[
\mu_\chi(\ell) = \begin{cases} 
-\frac{1}{2\pi} \sum_{\sigma \in G} \chi(\sigma) \otimes D_E(\ell^a) & \text{if } \chi \text{ is even}, \\
\frac{1}{2\pi} \sum_{\sigma \in G} \chi(\sigma) \otimes J_E(\ell^a) & \text{if } \chi \text{ is odd}.
\end{cases}
\]

Proof. Put \( r = \text{reg}_{E/F}(\langle \gamma \rangle) \). By Lemma \( \square \), the \( \psi \)-component of \( r \) is

\[
r_\psi = -\frac{1}{2\pi} \left( D_E(\psi(\ell)) \cdot \eta^+(\psi) + J_E(\psi(\ell)) \cdot \eta^-(\psi) \right).
\]

Since \( c_\chi(r) \) and \( \eta_\chi \) belong to the same \( G \)-eigenspace, it suffices to compare their \( t \)-components. By definition, we have \( (\eta_\chi)_t = \frac{1}{|G|} \eta^\chi(1) \). Moreover

\[
e_\chi(r) = \frac{1}{|G|} \sum_{\sigma \in G} \chi(\sigma) \otimes (\sigma \cdot t), \quad e_\chi(t) = \frac{1}{|G|} \sum_{\sigma \in G} \chi(\sigma) \otimes r_{t, o a} \quad (28)
\]

\[
= -\frac{1}{2\pi |G|} \sum_{\sigma \in G} \chi(\sigma) \otimes (D_E(\ell^a) \cdot \eta^+ + J_E(\ell^a) \cdot \eta^-). \quad (29)
\]

But \( D_E(\overline{\mathbb{P}}) = D_E(P) \) and \( J_E(\overline{\mathbb{P}}) = -J_E(P) \) for any \( P \in E(C) \), so that the terms involving \( J_E \) (resp. \( D_E \)) cancel out if \( \chi \) is even (resp. odd). \( \square \)

4 Modular curves in the adelic setting

Let \( A_f \) be the ring of finite adèles of \( \mathbb{Q} \). For any compact open subgroup \( K \subset GL_2(A_f) \), there is an associated smooth projective modular curve \( \overline{M}_K \) over \( \mathbb{Q} \). For example \( X(N) = \overline{M}_{K(N)} \) and \( X_1(N) = \overline{M}_{K_1(N)} \), where

\[
K(N) = \ker(GL_2(\overline{\mathbb{Z}}) \to GL_2(\mathbb{Z}/N\mathbb{Z})) \quad (30)
\]

\[
K_1(N) = \{ g \in GL_2(\overline{\mathbb{Z}}); g \equiv \begin{pmatrix} * & 1 \\ 0 & 1 \end{pmatrix} \pmod{N} \}. \quad (31)
\]

Documenta Mathematica 18 (2013) 395–412
The Riemann surface $\overline{M}_K(C)$ can be identified with the compactification of $GL_2(\mathbb{Q})/(\mathbb{A}_f^+ \times GL_2(\mathbb{A}_f))/K$. The set of connected components of $\overline{M}_K(C)$ is in bijection with $\hat{Z}/\det(K)$. For any $g \in GL_2(\mathbb{A}_f)$, we have an isomorphism $g:\overline{M}_K \cong \overline{M}_{g^{-1}Kg}$ over $\mathbb{Q}$, which is given on the complex points by $(\tau, h) \mapsto (\tau, hg)$. For any compact open subgroups $K' \subset K$ of $GL_2(\mathbb{A}_f)$, we have a finite morphism $\pi_{K'K} : \overline{M}_{K'} \to \overline{M}_K$.

The Hecke algebra $\mathcal{H}_K$ is the space of functions $K \backslash GL_2(\mathbb{A}_f)/K \to \overline{Q}$ with finite support, equipped with the convolution product $[\mathbb{H}]$. It acts on $H^1(\mathbb{M}_K(C), \overline{Q})$ and $\Omega^1(\mathbb{M}_K) \otimes \overline{Q}$. Let $T_K = T_{\mathcal{M}_K}$ be the image of $\mathcal{H}_K$ in $\text{End}_{\overline{Q}}(\Omega^1(\mathbb{M}_K) \otimes \overline{Q})$. Let

$$\langle \cdot, \cdot \rangle : H^1(\mathbb{M}_K(C), \mathbb{R})^* \times (\Omega^1(\mathbb{M}_K) \otimes \mathbb{R}) \to \mathbb{R}$$

be the perfect pairing induced by Poincaré duality. For any $T \in \mathcal{H}_K$, we have $\langle T \eta, \omega \rangle = \langle \eta, T' \omega \rangle$, where $T' \in \mathcal{H}_K$ is defined by $T'(g) = T(g^{-1})$, so that the action of $\mathcal{H}_K$ on $H^1(\mathbb{M}_K(C), \overline{Q} \otimes \mathbb{R})^*$ factors through $T_K$.

Following [15] 1.1.1, let $Q_K \subset K_2(\mathbb{M}_K) \otimes \mathbb{Q}$ be the subspace of Beilinson elements, and let

$$\mathcal{P}_K = \bigcup_{K' \subset K} \langle \pi_{K'K} \rangle_* Q_{K'} \subset K_2(\mathbb{M}_K) \otimes \mathbb{Q}. \tag{33}$$

Schappacher and Scholl [15] 1.1.2 proved that $\mathcal{P}_K \subset H^2_{\text{ét}}(\mathbb{M}_K, \mathbb{Q}(2))$ and that $\text{res}_{\mathbb{M}_K} \mathcal{P}_K$ is a $\mathbb{Q}$-structure of $H^1(\mathbb{M}_K(C), \mathbb{R})^*$ whose determinant with respect to the natural $\mathbb{Q}$-structure of $\mathcal{H}_{\mathcal{M}_K}$ is given by the leading term of $L(h^1(\mathbb{M}_K), s)$ at $s = 0$.

In the following, we assume $K = \prod_p K_p$, where $K_p$ a compact open subgroup of $GL_2(\mathbb{Q}_p)$. The Hecke algebra then decomposes as a restricted tensor product $\mathcal{H}_K = \bigotimes_p \mathcal{H}_{K_p}$. For any prime $p$, let $\overline{T}(p) \in \mathcal{H}_K$ (resp. $\widehat{T}(p, p) \in \mathcal{H}_K$) be the characteristic function of $K \left( \begin{smallmatrix} \varpi_p & 0 \\ 0 & 1 \end{smallmatrix} \right) K$ (resp. $K \left( \begin{smallmatrix} \varpi_p & 0 \\ 0 & \varpi_p \end{smallmatrix} \right)$), where $\varpi_p \in \mathbb{A}_f^+$ has component $p$ at the place $p$, and 1 elsewhere. Let $T(p)$ (resp. $\overline{T}(p, p)$) be the image of $\overline{T}(p)$ (resp. $\widehat{T}(p, p)$) in $T_K$. When $K$ needs to be specified, we write $T(p)_K$ or $T(p)_{\mathcal{M}_K}$.

For any integer $M \geq 1$, we let $\mathcal{H}_K^{(M)} \subset \mathcal{H}_K$ be the subalgebra generated by the $\mathcal{H}_{K_p}$ for $p \mid M$. We use the notation $T_K^{(M)}$ for the corresponding subalgebra of $T_K$.

**Lemma 10.** If $K(M) \subset K$ then $T_K^{(M)}$ is in the center of $T_K$.

**Proof.** For any prime $p \mid M$, we have $\mathcal{H}_{K_p} \cong GL_2(\mathbb{Z}_p)$ and by Satake the map $\overline{Q}[T, S, S^{-1}] \to \mathcal{H}_{K_p}$ given by $T \mapsto \overline{T}(p)$ and $S \mapsto \widehat{T}(p, p)$ is an isomorphism. In particular $\mathcal{H}_{K_p}$ is contained in the center of $\mathcal{H}_K$, whence the result.

Let $U_F \subset \hat{Z}$ denote the preimage of $\text{Gal}(\mathbb{Q}(\zeta_m)/F) \subset (\mathbb{Z}/m\mathbb{Z})^\times$ under the natural map $\hat{Z}^\times \to (\mathbb{Z}/m\mathbb{Z})^\times$ (note that $U_F$ does not depend on $m$). For any
compact open subgroup $K \subset \text{GL}_2(A_f)$ with $\det(K) = \hat{\mathbb{Z}}^\times$, let

$$K_F := \{ k \in K; \det(k) \in U_F \}. \quad (34)$$

Let $pr : A_f^\times \to \hat{\mathbb{Z}}^\times$ be the projection associated to the decomposition $A_f^\times \cong Q_{>0} \times \hat{\mathbb{Z}}^\times$.

**Definition 11.** Let $\gamma : \text{GL}_2(A_f) \to G$ be the composite morphism

$$\text{GL}_2(A_f) \xrightarrow{\det} A_f^\times \xrightarrow{pr} \hat{\mathbb{Z}}^\times \to G. \quad (35)$$

Note that there is an exact sequence

$$1 \to K_F \to K \xrightarrow{\gamma |_K} G \to 1. \quad (36)$$

The sequence $(36)$ induces a right action of $G$ on $\overline{M}_{K_F}$, and thus a left action of $G$ on $\Omega^1(\overline{M}_{K_F})$. Moreover, the curve $\overline{M}_K$ can be identified with $\overline{M}_{K_F}$ as a curve over $\mathbb{Q}$, and we have a bijection

$$\overline{M}_{K_F}(C) \xrightarrow{\cong} G \times \overline{M}_K(C) \quad (37)$$

$$[\tau, g] \mapsto (\gamma(g), [\tau, g]).$$

The action of $G$ on $\overline{M}_{K_F}(C)$ corresponds via $(37)$ to the action by translation on the first factor of $G \times \overline{M}_K(C)$.

Now let us consider the case $K = K_1(N)$, so that $\overline{M}_{K_F} \cong X_1(N)_F$. By the previous discussion, the image of $G$ in $\text{End} \Omega^1(X_1(N)_F) \otimes \mathbb{Q}$ is contained in $T_{X_1(N)_F}$, in order to ease notations, let $T = T_{X_1(N)_F} \subset \text{End} \Omega^1(X_1(N)_F) \otimes \mathbb{Q}$. Let $TG$ be the subalgebra of $T_{X_1(N)_F}$ generated by $T$ and $G$.

**Lemma 12.** The algebra $TG$ is commutative.

**Proof.** Note that $K(Nm) \subset K_1(N)_F$, so $T$ is commutative and commutes with $G$ by Lemma 10. Since $G$ is abelian, the result follows. \qed

Since $\Omega^1(X_1(N)_F) \cong \Omega^1(X_1(N)) \otimes F$, we can define the base change morphism $\nu_F : \text{End} \Omega^1(X_1(N)) \to \text{End} \Omega^1(X_1(N)_F)$ by $\nu_F(T) = T \otimes \text{id}_F$. For any $\alpha \in (\mathbb{Z}/m\mathbb{Z})^\times$, let $\sigma_\alpha$ be its image in $G$.

**Lemma 13.** For any prime $p \nmid Nm$, we have

$$\nu_F(T(p)_{X_1(N)}) = T(p)_{X_1(N)_F} \cdot \sigma_p \in TG \quad (38)$$

$$\nu_F(T(p,p)_{X_1(N)}) = T(p,p)_{X_1(N)_F} \cdot \sigma_p^2 \in TG. \quad (39)$$
Proof. Let \( g = \begin{pmatrix} \omega_p & 0 \\ 0 & 1 \end{pmatrix} \) and \( K := K_1(N) \cap g^{-1}K_1(N)g = K_1(N) \cap K_0(p) \). Note that \( \det K = \tilde{Z}^* \). Consider the following correspondence

\[
\begin{array}{c}
\mathcal{M}_K \\
\downarrow \alpha \\
X_1(N) \\
\downarrow \beta \\
\tilde{T}(p)X_1(N) \rightarrow X_1(N)
\end{array}
\]

(40)

where \( \alpha = \pi_{K,K_1(N)} \) and \( \beta = g^{-1} \circ \pi_{K,g^{-1}K_1(N)g} = \pi_{K,g^{-1}K_1(N)g} \circ g^{-1} \). Then \( T(p)X_1(N) = \beta \circ \alpha \) on \( \Omega^1(X_1(N)) \). Similarly \( T(p)X_1(N)_{\phi F} \) is defined by

\[
\begin{array}{c}
\mathcal{M}_{K_F} \\
\downarrow \alpha_F \\
X_1(N)_F \\
\downarrow \beta_F \\
\tilde{T}(p)X_1(N)_{\phi F} \rightarrow X_1(N)_F
\end{array}
\]

(41)

where \( \alpha_F \) is the natural projection and \( \beta_F \) is induced by \( g^{-1} \). Using the identification \( \mathcal{M}_{K_F} \approx \mathcal{M}_K \otimes F \) and the description (37) of the complex points, we obtain \( \alpha_F = \alpha \otimes \text{id}_F \) and \( \beta_F = \beta \otimes \gamma(g^{-1}) \). Since \( \gamma(g) = \sigma_{p^{-1}} \), we get \( T(p)X_1(N)_{\phi F} = \nu_F(T(p)X_1(N)) \circ (\sigma_p)_* \) and thus (38). The proof of (39) is similar.

5 A divisibility in the Hecke algebra

In this section we define and study a projection associated to \( E_F \) using the Hecke algebra of \( X_1(N)_F \).

Let \( \phi : X_1(N) \rightarrow E \) be a modular parametrization of the elliptic curve \( E \), and let \( \phi_F : X_1(N)_F \rightarrow E_F \) be the base change of \( \phi \) to \( F \). Consider the map

\[
e_F = \frac{1}{\deg \phi}(\phi_F)^*(\phi_F) \circ (\sigma_p)_*, \quad \Omega^1(X_1(N)_F).
\]

Lemma 14. We have \( e_F^2 = e_F \) and \( e_F \in T(G) \).

Proof. The first equality follows from \( (\phi_F)^*(\phi_F) = \deg \phi_F \).

We have \( e_F = \nu_F(e) \) where \( e = \frac{1}{\deg \phi} \phi^* \phi \in \text{End}_Q \Omega^1(X_1(N)) \). The image of \( e \) is the \( Q \)-vector space generated by \( \omega_f = 2i\pi f(z)dz \). Since \( f \) is a newform of level \( N \), the Atkin-Lehner-Li theory implies that \( e \in T_{X_1(N)} \). The result now follows from Lemma 13.

The space \( \Omega = \varprojlim_K \Omega^1(\mathcal{M}_K) \otimes \mathcal{Q} \) has a natural \( \text{GL}_2(A_f) \)-action and decomposes as a direct sum of irreducible admissible representations \( \Omega_\pi \) of \( \text{GL}_2(A_f) \). For any \( K \) we have \( \Omega^K = \Omega^1(\mathcal{M}_K) \otimes \mathcal{Q} \). Let \( \Pi(K) \) be the set of such \( \pi \) satisfying \( \Omega^K \neq \{0\} \). By (12) p. 393, we have

\[
\Omega^1(\mathcal{M}_K) \otimes \mathcal{Q} = \bigoplus_{\pi \in \Pi(K)} \Omega^K_\pi
\]

(42)
where each $\Omega^K_\pi$ is a simple $T_K$-module. In particular $T_K$ is a semisimple algebra. By Lemma [10] the algebra $T$ is contained in the center of $T_{K_1(N)_F}$. Using [12 Prop 2.11], we deduce that $T$ acts by scalar multiplication on each $\Omega^K_{\pi_1(N)_F}$, so there exists a morphism $\theta_\pi : T \to \mathbb{Q}$ such that $T$ acts as $\theta_\pi(T)$ on $\Omega^\pi_{K_1(N)_F}$. The multiplicity one and strong multiplicity one theorems [14] ensure that the characters $(\theta_\pi)_{\pi \in \Pi(K_1(N)_F)}$ are pairwise distinct.

For any $\chi \in \hat{G}$, let $\pi(f \otimes \chi)$ be the automorphic representation of $\text{GL}_2(A_f)$ corresponding to the modular form $f \otimes \chi$. We have $\pi(f \otimes \chi) \cong \pi(f) \otimes (\chi \circ \det)$, where $\chi : A_f^1/\mathbb{Q}_{\text{am}} \to \mathbb{C}^*$ denotes the ad\'elization of $\chi$, sending $\varpi_p$ to $\chi(p)$ for every $p \nmid m$. Since $\pi(f) \in \Pi(K_1(N)_F)$, it follows that $\pi(f \otimes \chi) \in \Pi(K_1(N)_F)$.

**Lemma 15.** For any prime $p \nmid Nm$, we have

$$\theta_\pi(f \otimes \chi)(T(p)) = a_p \chi(p)$$  \hspace{1cm} (43)

$$\theta_\pi(f \otimes \chi)(T(p,p)) = \chi(p)^2.$$  \hspace{1cm} (44)

**Proof.** We know that $\theta_\pi(f)(T(p)) = a_p$ and $\theta_\pi(f)(T(p,p)) = 1$. The equalities [43] and [44] follow formally from the fact that $\chi \circ \det$ is equal to $\chi(p)$ on the double coset $K_1(N)_F \left( \varpi_p \begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix} \right) K_1(N)_F$. \hfill $\Box$

Let $e_{f \otimes \chi} : \Omega^1(X_1(N)_F) \otimes \overline{\mathbb{Q}} \to \Omega^K_{\pi(f \otimes \chi)}$ be the projection induced by [22]. The multiplicity one theorems imply that $e_{f \otimes \chi} \in T$.

**Proposition 16.** The element $e_\chi e_F$ is divisible by $e_{f \otimes \chi}$ in $TG$.

**Proof.** Since $e_\chi$, $e_F$ and $e_{f \otimes \chi}$ are commuting projections, it suffices to prove that the image of $e_\chi e_F$ is contained in the image of $e_{f \otimes \chi}$. We know that the image of $\varphi^* : \Omega^1(E) \to \Omega^1(X_1(N))$ lies in the kernel of $T(p) - a_p \in T_{X_1(N)}$. Therefore the image of $\varphi^*_F$ lies in the kernel of $\nu_F(T(p)) - a_p$. Using Lemma [13] it follows that in $TG$ we have

$$T(p)\sigma_p e_F = a_p e_F.$$  \hspace{1cm} (45)

Applying $e_\chi$ to both sides and using the identity $e_\chi \sigma_p = \overline{\chi}(p)e_\chi$ yields

$$T(p) e_\chi e_F = a_p \chi(p) e_\chi e_F.$$  \hspace{1cm} (46)

The same argument shows that $T(p,p) e_\chi e_F = \chi(p)^2 e_\chi e_F$. The proposition now follows from Lemma [15] and the multiplicity one theorems. \hfill $\Box$
6 Proof of the main results

Recall that \( \varphi : X_1(N) \to E \) is a modular parametrization, and that \( \varphi_F \) is the base change of \( \varphi \) to \( F \). We have a commutative diagram

\[
\begin{array}{ccc}
K_2(X_1(N)_F) \otimes \mathbb{Q} & \xrightarrow{} & H^1(X_1(N)_F(\mathbb{C}), \mathbb{R})^* \\
\xrightarrow{\langle \varphi_F \rangle} & & \xrightarrow{\langle \varphi_F \rangle}
\end{array}
\]

where the horizontal maps are the regulator maps on \( X_1(N)_F \) and \( E_F \).

The strategy of the proof is to use Beilinson’s theorem on \( X_1(N)_F \) and then to get back to \( E_F \) using the Hecke algebra.

Let \( \mathcal{P}_{E/F} = (\varphi_F)_*\mathcal{P}_{X_1(N)_F} \subset K_2(E_F) \otimes \mathbb{Q} \). By [15, 1.1.2(iii)], we have \( \mathcal{P}_{E/F} \subset H^2_{\text{et}}(E_F, \mathbb{Q}(2)) \). We want to prove that \( R_{E/F} := \text{reg}_{E/F}(\mathcal{P}_{E/F}) \) is a \( \mathbb{Q} \)-structure satisfying \( \mathcal{F} \). Since \( \mathcal{P}_{X_1(N)_F} \) is stable by the Hecke algebra, the spaces \( \mathcal{P}_{E/F} \) and \( R_{E/F} \) are stable by \( G \).

For any \( \chi \in \hat{G} \), let \( R_\chi = e_\chi (R_{E/F} \otimes \overline{\mathbb{Q}}) \) and \( H_\chi = e_\chi (H_{E/F} \otimes \overline{\mathbb{Q}}) \). We want to compare \( R_\chi \) and \( H_\chi \).

We have

\[
\varphi_F^* R_\chi = e_\chi \varphi_F^* (R_{E/F} \otimes \overline{\mathbb{Q}})
\]

Similarly, we have

\[
\varphi_F^* H_\chi = e_\chi \varphi_F^* (H_{X_1(N)_F} \otimes \overline{\mathbb{Q}}).
\]

We will build on the following theorem of Schappacher and Scholl. Let \( \lambda_\chi \) be the unique element of \( (\overline{\mathbb{Q}} \otimes \mathbb{R})^* \) such that for every \( \psi : \overline{\mathbb{Q}} \to \mathbb{C}^* \), we have

\[
\psi(\lambda_\chi) = L'(f \otimes \chi, 0) \in \mathbb{C}^*.
\]

By [15, 1.2.4 and 1.2.6], we have

\[
e_{f \otimes \chi} (\text{reg}_{X_1(N)_F}(\mathcal{P}_{X_1(N)_F} \otimes \overline{\mathbb{Q}})) = \lambda_\chi \cdot e_{f \otimes \chi} (H_{X_1(N)_F} \otimes \overline{\mathbb{Q}}).
\]

By Prop. [16] the equality [50] remains true when \( e_{f \otimes \chi} \) is replaced by \( e_\chi e_F \), so that \( \varphi_F^* R_\chi = \lambda_\chi \cdot \varphi_F^* H_\chi \) by [48] and [49]. Since \( \varphi_F^* \) is injective, we get \( R_\chi = \lambda_\chi \cdot H_\chi \). Put \( V = H^1(E_F, \mathbb{R})^* \) and \( V_\chi = e_\chi (V \otimes \overline{\mathbb{Q}}) \) for any \( \chi \in \hat{G} \).

Lemma 17. The \( \mathbb{R}[G] \)-module \( V \) is free of rank 1.

Proof. By Poincaré duality \( V \cong \text{Hom}_\mathbb{Q}(\Omega^1(E_F), \mathbb{R}) \), and \( \Omega^1(E_F) \cong \Omega^1(E) \otimes F \) is free of rank 1 over \( \mathbb{Q}[G] \) by the normal basis theorem.

We will use the following lemma from linear algebra. Recall that if \( B \) is an \( A \)-algebra and \( N \) is a \( B \)-module, an \( A \)-structure of \( N \) is an \( A \)-submodule \( M \subset N \) such that \( M \otimes_A B \cong N \).

Lemma 18. Let \( M \) be a \( \mathbb{Q}[G] \)-submodule of \( V \). The following conditions are equivalent:

\[
\text{(i) } M \text{ is free of rank } 1.
\text{(ii) } M \text{ is an } A \text{-structure of } N.
\text{(iii) } M \otimes_A B \cong N.
\]
(i) $M$ is a $\mathbb{Q}$-structure of the real vector space $V$.

(ii) For any $\chi \in \hat{G}$, the space $M_\chi := e_\chi(M \otimes \overline{\mathbb{Q}})$ is a $\overline{\mathbb{Q}}$-structure of the $\overline{\mathbb{Q}} \otimes \mathbb{R}$-module $V_\chi$.

Moreover, if these conditions hold, then $M$ is free of rank 1 over $\mathbb{Q}[G]$.

Proof. The implication (i) $\Rightarrow$ (ii) follows from the isomorphisms $M_\chi \otimes \overline{\mathbb{Q}} (\overline{\mathbb{Q}} \otimes \mathbb{R}) \cong e_\chi (M \otimes \overline{\mathbb{Q}} \otimes \mathbb{R}) \cong V_\chi$. Let us assume (ii). By Lemma 18 the $\overline{\mathbb{Q}} \otimes \mathbb{R}$-module $V_\chi$ is free of rank 1, so that $\dim_{\overline{\mathbb{Q}}} M_\chi = 1$. Since $M \otimes \overline{\mathbb{Q}} \cong \oplus_{\chi \in \hat{G}} M_\chi$, we get $\dim_{\overline{\mathbb{Q}}} M = d$. Moreover $M \otimes \overline{\mathbb{Q}} \otimes \mathbb{R}$ generates $V \otimes \overline{\mathbb{Q}} \otimes \mathbb{R}$, so that any $\mathbb{Q}$-basis of $M$ is actually free over $\mathbb{R}$.

Finally, if (i) holds, then $M$ is isomorphic to the regular representation of $G$ by Lemma 17, so that $M$ is free of rank 1 over $\mathbb{Q}[G]$. $\square$

Using Lemma 18 with the $\mathbb{Q}$-structure $H_{EF}$, we see that $H_\chi$ is a $\overline{\mathbb{Q}}$-structure of $V_\chi$. By Lemma 8 the 1-form $\eta_\chi$ is a $\overline{\mathbb{Q}}$-basis of $H_\chi$.

Proof of Theorem 2. Since $R_\chi = \lambda_\chi \cdot H_\chi$ is a $\overline{\mathbb{Q}}$-structure of $V_\chi$, Lemma 18 implies that $R_{EF}$ is a $\mathbb{Q}$-structure of $V$. Moreover, the determinant of $R_{EF} \otimes \mathbb{Q}$ with respect to $H_{EF} \otimes \overline{\mathbb{Q}}$ is represented by $\delta := \prod_{\chi \in \hat{G}} \lambda_\chi \in (\overline{\mathbb{Q}} \otimes \mathbb{R})^\times$. Note that $\sigma(\lambda_\chi) = \lambda_{\sigma \chi}$ for any $\sigma \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, so that $\delta$ lies in the image of $\mathbb{R}^\times$ in $(\overline{\mathbb{Q}} \otimes \mathbb{R})^\times$. Using the natural evaluation map $(\overline{\mathbb{Q}} \otimes \mathbb{R})^\times \hookrightarrow C^\times$, we get in fact $\delta = \prod_{\chi \in \hat{G}} L(f \otimes \chi, 0)$. Since the natural map $\mathbb{R}^\times/\mathbb{Q}^\times \to (\overline{\mathbb{Q}} \otimes \mathbb{R})^\times/\overline{\mathbb{Q}}^\times$ is injective, we conclude that $\det(R_{EF}) = L(d)(E_F, 0) \cdot \det(H_{EF})$ by 8. $\square$

Proof of Theorem 1. We know from Theorem 2 that $R_{EF}$ is a $\mathbb{Q}$-structure of $V$. Since $R_{EF}$ is stable by $G$, it is free of rank 1 over $\mathbb{Q}[G]$ by Lemma 18. Let $\gamma \in \mathcal{P}_{EF}$ such that $R_{EF} = Q[G] \cdot \text{reg}_{EF}(\gamma)$. Replacing $\gamma$ by a suitable integer multiple, we may assume that $\gamma$ has a representative $\overline{\gamma} \in F(E) \otimes F(E)$. Let $\ell = \beta(\overline{\gamma})$. For any $\chi \in \hat{G}$, we have $R_\chi = \mu_\chi(\ell) H_\chi$ by Prop. 9 where $\mu_\chi(\ell)$ is given by 20. It follows that $\mu_\chi(\ell)/\lambda_\chi \in \overline{\mathbb{Q}}^\times$. Since $\lambda_\chi$ and $\mu_\chi(\ell)$ belong to $\mathbb{Q}(\chi) \otimes \mathbb{R}$, we have in fact $\mu_\chi(\ell)/\lambda_\chi \in \mathbb{Q}(\chi)^\times$. Moreover, the definitions of $\lambda_\chi$ and $\mu_\chi(\ell)$ show that $\tau(\lambda_\chi) = \lambda_{\chi^\tau}$ and $\tau(\mu_\chi(\ell)) = \mu_{\chi^\tau}(\ell)$ $(\tau \in \text{Gal}(\mathbb{Q}(\chi)/\mathbb{Q}))$. (51)

Lemma 19. Let $(a_\chi)_{\chi \in \hat{G}}$ be a family of algebraic numbers, with $a_\chi \in \mathbb{Q}(\chi)^\times$, such that $\tau(a_\chi) = a_{\chi^\tau}$ for any $\chi$ and any $\tau \in \text{Gal}(\mathbb{Q}(\chi)/\mathbb{Q})$. Then there exists a unique $a \in \mathbb{Q}[G]^\times$ such that for every $\chi \in \hat{G}$, we have $\chi(a) = a_\chi$.

Proof. The canonical morphism of $\mathbb{Q}$-algebras $\Psi : \mathbb{Q}[G] \to \prod_{\chi \in \hat{G}} \mathbb{Q}(\chi)$ is injective and its image is contained in the subalgebra $W$ of families $(b_\chi)_\chi$ satisfying $\tau(b_\chi) = b_{\chi^\tau}$ for any $\chi$ and $\tau$. Writing $\hat{G}$ as a disjoint union of Galois orbits, we have $\dim_{\mathbb{Q}} W = \# \hat{G} = d$, so that $\Psi$ is an isomorphism. $\square$
Let $\ell(\chi)$, we get $a \in \mathbb{Q}[G]^{*}$ such that $\mu_{\chi}(\ell) = \chi(a)\lambda_{\chi}$ for any $\chi$. Since $\mu_{\chi}(a\ell) = \chi(a)\mu_{\chi}(\ell)$, replacing $\ell$ with a suitable integer multiple of $a\ell$ results in $\mu_{\chi}(\ell) \sim_{\mathbb{Q}} \lambda_{\chi}$ for any $\chi$. Evaluating everything in $\mathbb{C}$ yields $\chi$. $\hfill \Box$

**Proof of Corollary.** Let us first recall the Dedekind-Frobenius formula for group determinants. If $a : G \to \mathbb{C}$ is an arbitrary function, let $A$ be the matrix $(a(gh^{-1}))_{g,h \in G}$. Then

$$\det(A) = \prod_{\chi \in \hat{G}} \sum_{g \in G} \chi(g) a(g). \quad (52)$$

Let $\ell \in \mathbb{Z}[E(Q)]^{G_{r}}$ be a divisor satisfying the identities (1) of Theorem 1. Assume first $F$ is real. Put $\ell_{i} := \ell^{\sigma_{i}}$ for $1 \leq i \leq d$. Using (52) with $a(\sigma) = D_{E}(\ell^{\sigma})$ yields

$$\det(D_{E}(\ell_{i}^{\sigma}))_{1 \leq i,j \leq d} \sim_{\mathbb{Q}^{*}} \prod_{\chi \in \hat{G}} \pi L(E \otimes \chi, 0) \sim_{\mathbb{Q}^{*}} \pi^{-d} L(E_{F}, 2) \quad (53)$$

where the last relation follows from (8) and Prop. 4.

Assume now $F$ is complex. Put $\ell_{i} := \ell^{\sigma_{i}^{-1}}$ for $1 \leq i \leq d/2$. We use (52) with the function $a(\sigma) = D_{E}(\ell^{\sigma}) + J_{E}(\ell^{\sigma})$. Indexing the lines and columns of $A$ by \( \sigma_{1}, \sigma_{1}, \ldots, \sigma_{d/2}, \sigma_{d/2} \), we see that $A$ consists of blocks of the form

$$\begin{pmatrix} x + y & x - y \\ x - y & x + y \end{pmatrix},$$

where $x = D_{E}(\ell^{\sigma_{i}^{-1}})$ and $y = J_{E}(\ell^{\sigma_{i}^{-1}})$. Elementary operations on the lines and columns of $A$ thus gives

$$\det A = 2^{d} \det(D_{E}(\ell_{i}^{\sigma}))_{1 \leq i,j \leq d/2} \cdot \det(J_{E}(\ell_{i}^{\sigma}))_{1 \leq i,j \leq d/2}. \quad (54)$$

On the other hand, we have

$$\sum_{\sigma \in G} \chi(\sigma) a(\sigma) = \begin{cases} \sum_{\sigma \in G} \chi(\sigma) D_{E}(\ell^{\sigma}) & \text{if } \chi \text{ is even}, \\ \sum_{\sigma \in G} \chi(\sigma) J_{E}(\ell^{\sigma}) & \text{if } \chi \text{ is odd}, \end{cases} \quad (55)$$

so that we conclude as in the first case. $\hfill \Box$

**Further remarks and a conjecture**

The proof of Theorem 2 relies crucially on the hypothesis that $F/\mathbb{Q}$ is abelian. Since the field of constants of a modular curve is always an abelian extension of $\mathbb{Q}$, it is not possible to cover a non-abelian base change of $E$ by a usual modular curve. In fact, in the case $F/\mathbb{Q}$ is not abelian, we have no example of a (non CM) elliptic curve $E$ over $\mathbb{Q}$ for which we can prove Zagier’s conjecture for $L(E_{F}, 2)$. However, Theorem 1 suggests the following conjecture for Artin-twisted $L$-values. For simplicity, we restrict to the case $F$ is totally real.
Conjecture 20. Let $E$ be an elliptic curve defined over $\mathbb{Q}$, and let $F$ be a finite Galois totally real extension of $\mathbb{Q}$. There exists a divisor $\ell \in \mathbb{Z}[E(\mathbb{Q})]^\text{Gal}(\mathbb{Q}/F)$ satisfying Goncharov and Levin’s conditions such that for every Artin representation $\rho : \text{Gal}(F/\mathbb{Q}) \to \text{GL}_d(\mathbb{C})$, we have

$$L^{(d)}(E \otimes \rho, 0) \sim_{\mathbb{Q}} \pi^{-d} \det\left( \sum_{\sigma \in G} \rho(\sigma) D_E(\ell^\sigma) \right).$$

(56)

Conversely, for every $\ell \in \mathbb{Z}[E(\mathbb{Q})]^\text{Gal}(\mathbb{Q}/F)$ satisfying Goncharov and Levin’s conditions and for every $\rho : \text{Gal}(F/\mathbb{Q}) \to \text{GL}_d(\mathbb{C})$, we have

$$\pi^{-d} \det\left( \sum_{\sigma \in G} \rho(\sigma) D_E(\ell^\sigma) \right) \in L^{(d)}(E \otimes \rho, 0) \cdot \mathbb{Q}(\text{tr } \rho),$$

(57)

where $\mathbb{Q}(\text{tr } \rho)$ is the field generated by the traces of $\rho$.

Noting that the identities (56) and (57) are compatible with taking direct sums of Artin representations. In fact, Conjecture 20 is a refinement of Zagier’s conjecture for $L(E_F, 2)$, in the sense that taking the product over irreducibles $\rho$ with multiplicities $\text{dim}(\rho)$ gives the conjecture for $E_F$. Note that the analytic continuation and the functional equation of $L(E \otimes \rho, s)$ are only conjectural in general.

It would be interesting to investigate the rational factors arising in Theorem 1. As a matter of fact, even for $F = \mathbb{Q}$, we don’t know how to predict the rational factor appearing in Zagier’s conjecture. The Bloch-Kato conjecture predicts the exact value of $L(E_F, 2)$ (at least up to a unit in the ring of integers of $F$), but the link between both conjectures remains to be worked out. In fact, in this setting it may be more natural to investigate the equivariant Tamagawa number conjecture of Burns and Flach [9, Part 2, Conjecture 3], which predicts the equivariant $L$-value $L(F_E, 2) \in \mathbb{R}[G]^+$ up to a unit in an order of $\mathbb{Q}[G]$. Taking norms down to $\mathbb{Q}$, this predicts $L(E_F, 2)$ up to sign. The deep work of Gealy [10] on the Bloch-Kato conjecture for modular forms, which uses Kato’s Euler system, could be used to tackle this equivariant conjecture. Note also that if $F$ is abelian and real, then Theorem 1 gives a link between $L(F_E, 2)$ and the vector-valued elliptic dilogarithm $D_E(\ell) = \sum_{\sigma \in G} D_E(\ell^\sigma)[\sigma]$.

Finally, although the divisor $\ell$ produced by Theorem 1 is inexplicit in general, it would be interesting to try to bound the number field generated by the support of $\ell$, as well as the heights of the points involved.

Communicated by Ulf Rehmann

Abstract. Conjugacy classes of outer automorphisms of order 3 of simple algebraic groups of classical type $D_4$ are classified over arbitrary fields. There are two main types of conjugacy classes. For one type the fixed algebraic groups are simple of type $G_2$; for the other type they are simple of type $A_2$ when the characteristic is different from 3 and are not smooth when the characteristic is 3. A large part of the paper is dedicated to the exceptional case of characteristic 3. A key ingredient of the classification of conjugacy classes of trialitarian automorphisms is the fact that the fixed groups are automorphism groups of certain composition algebras.

1. Introduction

The projective linear algebraic group $\text{PGL}_n$ admits two types of conjugacy classes of outer automorphisms of order two. For one type the fixed subgroups are symplectic groups; for the other type the fixed groups are orthogonal groups, which are not smooth when the base field has characteristic 2.

The picture is similar for trialitarian automorphisms (i.e., outer automorphisms of order three) of the algebraic groups $G = \text{PGO}_8^+$ or $G = \text{Spin}_8$. There are two types of conjugacy classes. For one type the fixed groups are simple of type $G_2$; for the other type they are simple of type $A_2$ when the characteristic is different from 3, and not smooth when the characteristic is 3. The first case is well known: there is a split exact sequence

$$1 \to \text{Int}(G) \to \text{Aut}(G) \to S_3 \to 1$$

where the permutation group of three elements $S_3$ is viewed as the group of automorphisms of the Dynkin diagram of type $D_4$.

\[ \begin{array}{c}
\alpha_1 \\
\alpha_2 \\
\hdashline \\
\alpha_3 \\
\alpha_4
\end{array} \]

(The simple roots $\alpha_i$ are numbered after [Bou81]). Viewing $G$ as a Chevalley group, there is a canonical section of the exact sequence (1.1) which leads to a distinguished trialitarian automorphism of $G$, known as a graph automorphism.

The permutation $\rho: \alpha_1 \mapsto \alpha_3 \mapsto \alpha_4 \mapsto \alpha_1, \alpha_2 \mapsto \alpha_2$ of the Dynkin diagram above induces a permutation of all simple roots $\alpha$ of $G$, also denoted by $\rho$.

The graph automorphism is such that $\rho(x_\alpha(u)) = x_{\rho(\alpha)}(u)$ for each simple root group $x_\alpha(u)$ of $G$ (see [Ste68b] or Section 2). The subgroup of $G$ fixed by the graph automorphism is of type $G_2$.

The aim of this paper is to describe all conjugacy classes of trialitarian automorphisms of simple algebraic groups of classical inner type $D_4$ over arbitrary fields, from the (functorial) point of view of algebraic groups. In particular the case of characteristic 3 has not been considered before in this setting, and a large part of this paper is dedicated to it. In a previous paper [CKT12], three of the authors gave a description based on the (known) classification of symmetric composition algebras of dimension 8 and a correspondence between symmetric compositions and trialitarian automorphisms. Here we take a different approach: we classify trialitarian automorphisms directly, and then use the correspondence to derive a new proof of the classification of symmetric composition algebras of dimension 8.

In the first part of the paper, consisting of §§2–7, we consider algebraic groups over algebraically closed fields. The first step, achieved in §§2–3, is to prove

\[ \text{Trialitarian automorphisms (or more generally automorphisms of finite order) of simple Lie algebras have been extensively studied, see i.a., [Hel78], [Kac69], [Knu09], [Rec10] and [WG68].} \]
that every trialitarian automorphism admits an invariant maximal torus. This is clear in characteristic different from 3 since trialitarian automorphisms are semisimple and semisimple automorphisms admit invariant tori (see [BM55], [Ste68a] or [Pia85]). However we did not find references for the result over fields of characteristic 3. In §§4–5, we recall the correspondence between symmetric compositions and trialitarian automorphisms set up in [CKT12], and use it to define two standard trialitarian automorphisms $\rho_0$ and $\rho_0$ corresponding respectively to the para-Zorn composition $\diamond$ and the split Okubo composition $\triangle$ on the 8-dimensional quadratic space $(C,n)$ of Zorn matrices. We then define in §6 a split maximal torus $T$ of $PGO^+(n)$ invariant under $\rho_0$ and $\rho_0$, and use it in §7 to show that over an algebraically closed field, every trialitarian automorphism of $PGO^+(n)$ is conjugate to $\rho_0$ or to $\rho_0$. In view of the results of §3, and since over a separably closed field all the maximal tori are conjugate, it suffices to consider trialitarian automorphisms that preserve the given torus $T$.

In the second part of the paper, we describe the subgroups of $PGO^+_8$ fixed under trialitarian automorphisms, over an arbitrary field $F$. These fixed subgroups are the automorphism groups of the corresponding symmetric composition algebras. They are divided into two classes according to their isomorphism class over an algebraic closure. In §8 we show that for one of the classes the symmetric composition algebras are para-octonion algebras and the automorphism groups are of type $G_2$; for the other the symmetric composition algebras are Okubo algebras and the automorphism groups are of type $A_2$ when the characteristic is different from 3. The following §§9–11 deal with the case of Okubo algebras in characteristic 3. A particular type of idempotents, which we call quaternionic idempotents, is singled out in §9, where we show that the existence of a quaternionic idempotent characterizes split Okubo algebras, and that split Okubo algebras over a field of characteristic 3 contain a unique quaternionic idempotent. This idempotent is used to describe in §§10–11 the group scheme $\text{Aut}(\triangle)$ of automorphisms of the split Okubo algebra in characteristic 3. (The corresponding groups of rational points already occur in various settings, see [Tit59], [GL83] and [Eld99].) Using the description of $\text{Aut}(\triangle)$, we recover in §12 the classification of Okubo algebras over arbitrary fields of characteristic 3 by a cohomological approach. Finally, in §13 we give a cohomological version of the correspondence between symmetric compositions and trialitarian automorphisms, and show that the only groups of classical type $^{1,2}D_4$ that admit trialitarian automorphisms are $PGO^+(n)$ and $\text{Spin}(n)$ for $n$ a 3-Pfister quadratic form. Note that the cohomology we use is faithfully flat finitely presented cohomology, or fppf-cohomology, since we need to deal with inseparable base field extensions. (Galois cohomology would be sufficient for fields of characteristic different from 3.) We refer to [DG70], [Wat79] and [KO74] for details on fppf-cohomology and descent theory.

The fact that the composition algebras of octonions could be used to define trialitarian automorphisms was already known to Élie Cartan (see [Car25]). We refer to [KMRT98] and [SV00] for historical comments on triality.
Chernousov, Elduque, Knus, Tignol

If not explicitly mentioned $F$ denotes throughout the paper an arbitrary field and the algebras considered are defined over $F$.

We gratefully thank Philippe Gille for his help during the preparation of this paper.

2. Generators and relations in Chevalley groups

We recall in this section results about Chevalley groups which will be used later. Let $G$ be a split simple simply connected group over $F$. Since $G$ is a Chevalley group over $F$, its $F$-structure is well known. For details and proofs of all standard facts about $G(F)$ used in this section we refer to [Ste68b]. Let $G$ be the Lie algebra of $G$. Choose a split maximal torus $T \subset G$ and a Borel subgroup $T \subset B \subset G$. Let $\Sigma = \Sigma(G,T)$ be the root system of $G$ relative to $T$. The Borel subgroup $B$ determines an ordering of $\Sigma$, hence the system of simple roots $\Pi = \{\alpha_1, \ldots, \alpha_n\}$. We pick a Chevalley basis [Ste68b]

$$\{H_{\alpha_1}, \ldots, H_{\alpha_n}, X_{\alpha}, \alpha \in \Sigma\}$$

in $G$ corresponding to the pair $(T,B)$. This basis is unique up to signs and automorphisms of $G$ which preserve $B$ and $T$ (see [Ste68b], §1, Remark 1). The group $G(F)$ is generated by the so-called root subgroups $U_\alpha = \langle x_\alpha(u) | u \in F \rangle$, where $\alpha \in \Sigma$ and

$$x_\alpha(u) = \sum_{n=0}^{\infty} u^n X^n_\alpha / n!$$

(we refer to [Ste68b] for the definition of the operators $X^n_\alpha / n!$ in the case $\text{char}(F) = p > 0$, see also [SGA3]).

If $\alpha \in \Sigma$ and $t \in G_m(F)$, the following elements are also of great importance:

$$w_\alpha(t) = x_\alpha(t)x_{-\alpha}(-t^{-1})x_\alpha(t) \quad \text{and} \quad h_\alpha(t) = w_\alpha(t)w_\alpha(1)^{-1}.$$

To ease notation we set $w_\alpha = w_\alpha(1)$. The elements $h_\alpha(t)$ give rise to a cocharacter $h_\alpha : G_m \to T$ whose image is $T_\alpha = T \cap G_\alpha$ where $G_\alpha$ is the subgroup generated by $U_{\pm \alpha}$.

Example 2.2. The group $G_\alpha$ is isomorphic in a natural way to $\text{SL}_2$. This isomorphism is given by

$$x_\alpha(u) \mapsto \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix}, \quad x_{-\alpha}(u) \mapsto \begin{pmatrix} 1 & 0 \\ u & 1 \end{pmatrix},$$

$$h_\alpha(t) \mapsto \begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix}, \quad w_\alpha \mapsto \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

The following relations hold in $G$ (cf. [Ste68b], Lemma 19 a), Lemma 28 b), Lemma 20 a)):

$$T = T_{\alpha_1} \times \cdots \times T_{\alpha_n};$$

for any two roots $\alpha, \beta \in \Sigma$ we have

$$w_\alpha h_\beta(t) w_\alpha^{-1} = h_{w_\alpha(\beta)}(t);$$

Documenta Mathematica 18 (2013) 413–468
where \( \varepsilon = \pm 1 \).
We finally recall a commutator formula due to Chevalley, see [Ste68b, Lemma 32']. For arbitrary roots \( \alpha, \beta \), one has
\[
(w_\alpha X_\beta w_\alpha^{-1} = \varepsilon X_{w_\alpha(\beta)}
\]
where \( \varepsilon = \pm 1 \).

3. Invariant Tori

The main result in this section is the existence of invariant tori under trialitarian automorphisms. As already mentioned in the introduction the claim is known over fields of characteristic different from 3. We give here a proof for any field \( F \).

We first reduce to the case of simply connected groups. Let \( G \) be a split simple simply connected group of type \( D_4 \) over \( F \), and let \( G^{\text{ad}} \) be the isogenous adjoint group. We have a canonical exact sequence
\[
1 \to \mu_2 \times \mu_2 \to G \to G^{\text{ad}} \to 1,
\]
where \( \mu_2 \) is the group scheme of square roots of unity. Every automorphism of \( G \) induces an automorphism of \( G^{\text{ad}} \).

Lemma 3.2. Every trialitarian automorphism \( \phi \) of \( G^{\text{ad}} \) lifts to a trialitarian automorphism \( \tilde{\phi} \) of \( G \). If \( T \) is a torus in \( G \) invariant under \( \tilde{\phi} \), the image of \( T \) in \( G^{\text{ad}} \) is invariant under \( \phi \).

Proof. Viewing \( G \) as a Chevalley group, we have a group of graph automorphisms of \( G \) isomorphic to \( S_3 \) defined over \( F \), and we may consider the semidirect products \( G \rtimes S_3 \) and \( G^{\text{ad}} \rtimes S_3 \). Note that
\[
\text{Aut}(G^{\text{ad}}) = \text{Int}(G^{\text{ad}}) \rtimes S_3 = G^{\text{ad}} \rtimes S_3,
\]
and the exact sequence (3.1) yields an exact sequence
\[
1 \to \mu_2 \times \mu_2 \to G \rtimes S_3 \to G^{\text{ad}} \rtimes S_3 \to 1.
\]
Consider the associated exact sequence in faithfully flat finitely presented cohomology (see [DG70, p. 272–273]):
\[
(\mu_2 \times \mu_2)(F) \to (G \rtimes S_3)(F) \to (G^{\text{ad}} \rtimes S_3)(F) \to H^1_{\text{fppf}}(F, \mu_2 \times \mu_2).
\]
Viewing \( \phi \) as an element in \( (G^{\text{ad}} \rtimes S_3)(F) \), we may consider its image \( \phi' \) in \( H^1_{\text{fppf}}(F, \mu_2 \times \mu_2) \). We have \( \phi'^2 = 1 \) because \( H^1_{\text{fppf}}(F, \mu_2 \times \mu_2) \) has exponent 2, and \( \phi'^3 = 1 \) because \( \phi'^3 = 1 \), hence \( \phi' = 1 \). It follows that \( \phi \) has a preimage \( \phi'' \) in \( (G \rtimes S_3)(F) \). We have \( \phi''' \in (\mu_2 \times \mu_2)(F) \) since \( \phi' = 1 \), hence conjugation by \( \phi''' \) in \( G \rtimes S_3 \) restricts to an automorphism \( \tilde{\phi} \) of order 3 of \( G \). The induced automorphism on \( G^{\text{ad}} \) is \( \phi \), so \( \tilde{\phi} \) is a lift of \( \phi \) and is an outer automorphism.
A torus $T$ in $G$ is invariant under $\tilde{\phi}$ if and only if it centralizes $\phi''$. It is then clear that the image of $T$ in $G^{ad}$ is invariant under $\phi$. \qed

The crucial tool to prove the existence of invariant tori is the following result of G. Harder:

**Proposition 3.3** ([Har75, Lemma 3.2.4]). Let $F$ be an infinite field and let $G$ be a split simple simply connected algebraic group or a split simple adjoint algebraic group of type $\mathbb{D}_4$ over $F$. Let $\phi \in \text{Aut}(G)(F)$ be an outer automorphism of order 3 of $G$ over $F$. There exists a parabolic subgroup $P \subset G$ such that $H = P \cap P^{\phi} \cap P^{\phi^2}$ is a reductive subgroup of $G$ of dimension 10 defined over $F$ whose semi-simple part $H' = [H,H]$ is a simple group of type $A_2$.

We first make some comments about properties of $H$. Assume that $F$ is separably closed. Being a reductive group, $H$ is an almost direct product of its central 2-dimensional torus $S$ and its derived subgroup $H'$. Let $T$ be an arbitrary maximal torus in $H$. Since $\dim T = 4$, $T$ is also maximal in $G$. It then follows that $H'$ is generated by some root subgroups $U_{\pm \gamma}$ and $U_{\pm \delta}$ where $\gamma, \delta$ are roots in $G$ with respect to $T$. Note that every such subgroup in $G$ is simply connected, hence $H' \cong \text{SL}_3$. Let $\alpha_1, \ldots, \alpha_4$ be the basis of the root system $\Sigma$ of type $\mathbb{D}_4$ as defined in [Bou81], see also (1), and let $\beta = \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 \in \Sigma$. For an arbitrary pair of roots $\gamma, \delta$ with $(\gamma, \delta) = -1$ in $\Sigma$ there exists an element $w$ in the corresponding Weyl group such that $w(\gamma) = \alpha_2$, $w(\delta) = \beta$. In view of (2.5) we may then assume without loss of generality that $H'$ is the subgroup $G_{(\alpha_2,\beta)}$ generated by the root subgroups $U_{\pm \alpha_2}$ and $U_{\pm \beta}$.

Another ingredient in the proof of existence of invariant tori is the following lemma. Let $G$ be a split simple simply connected algebraic group of type $\mathbb{D}_4$ over a field $F$. Let $T \subset B$ be a maximal split torus and a Borel subgroup in $G$. As usual, the subgroup $B$ determines the ordering in the root system $\Sigma = \Sigma(G,T)$ of $G$ with respect to $T$ and hence a basis of $\Sigma$. As above we set $\beta = \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4$.

**Lemma 3.4.** Assume that $F$ is a field of characteristic 3. Let $\rho$ be the graph automorphism of $G$. If $x = x_{\alpha_2}(u)$, where $u \in F^\times$, there exists $g \in B(F) \times \langle \rho \rangle$ such that $g(\rho x)g^{-1} = \rho x_{\alpha_2}(u_1)x_\beta(u_2)x_{\alpha_2 + \beta}(u_3) \in B(F) \times \langle \rho \rangle$, where $u_1, u_2 \in F^\times$ and $u_3 \in F$.

**Proof.** The proof is based on the commutator formula (2.6). Note that for a group of type $G_2$ in the commutator formula applied to two simple roots $\gamma_1, \gamma_2$ of $G_2$ (numbered as in [Bou81]), all integers $c_{ij}$ are non-zero modulo 3.

Consider the subgroup $\mathcal{G}$ of $G$ of elements invariant under $\rho$, which is of type $G_2$. It contains the subgroup of $G$ generated by $G_{\alpha_2}, G_{\beta}$ of type $A_2$. Also, the root subgroups in $\mathcal{G}$ corresponding to its two simple roots $\gamma_1$ and $\gamma_2$ are generated by elements $x_{\alpha_2}(u)$ and $x_{\alpha_1}(v)x_{\alpha_3}(v)x_{\alpha_4}(v)$. Taking into consideration (2.6) and the fact that $\rho$ commutes with $x_{\alpha_1}(v)x_{\alpha_3}(v)x_{\alpha_4}(v)$ we can write the element

$$X = (x_{\alpha_1}(1)x_{\alpha_3}(1)x_{\alpha_4}(1)) (\rho x_{\alpha_2}(u)) (x_{\alpha_1}(1)x_{\alpha_3}(1)x_{\alpha_4}(1))^{-1}$$

\[2\text{We are indebted to Philippe Gille for pointing out this result to us.}\]
in the form
\begin{equation}
X = \rho(x_{\alpha_2}(v_1)x_{\beta}(v_2)x_{\alpha_2+\beta}(v_3))YZ
\end{equation}
where $v_1, v_2 \neq 0$ (see the above remark about the integers $c_{ij}$) and
\begin{align*}
Y &= x_{\alpha_1+\alpha_2}(v_4)x_{\alpha_3+\alpha_2}(v_5)x_{\alpha_4+\alpha_2}(v_6) \\
Z &= x_{\alpha_1+\alpha_3+\alpha_2}(v_7)x_{\alpha_1+\alpha_2+\alpha_2}(v_8)x_{\alpha_3+\alpha_4+\alpha_2}(v_9)
\end{align*}
where $v_i \in F$. We now note that in the expression (3.5) for $X$ the root elements $x_{\alpha_1}(\cdot), x_{\alpha_3}(\cdot)$ and $x_{\alpha_4}(\cdot)$ are missing and the commutator of the other root subgroups which appear in (3.5) is either 1 or of the form $x_{\alpha_2+\beta}(\cdot)$ which is in the center of $B(F) \rtimes \langle \rho \rangle$. So there is no harm if we ignore factors $x_{\alpha_2+\beta}(\cdot)$ in the computations below and thus we shall assume that all root subgroups $x_\gamma$ which appear commute with each other. Since $\rho x$ has order 3 (because $\rho$ and $x$ commute and $x^3 = x_{\alpha_2}(3\gamma) = 1$) it follows almost immediately that $Z$ satisfies the “cocycle condition” $Z\rho(Z)\rho^2(Z) = 1$. Since $\rho$ acts freely on the subgroup
\begin{equation*}
A = \langle x_{\alpha_1+\alpha_2+\alpha_1}(\cdot) \rangle \times \langle x_{\alpha_1+\alpha_2+\alpha_2}(\cdot) \rangle \times \langle x_{\alpha_3+\alpha_2+\alpha_4}(\cdot) \rangle
\end{equation*}
one can see that $Z$ can be written in the form $Z = \rho^{-1}Z_1\rho Z_1^{-1}$ where $Z_1 \in A$. We then have
\begin{align*}
Z_1^{-1}XZ_1 &= Z_1^{-1}\rho x_{\alpha_2}(v_1)x_{\beta}(v_2)Y(\rho^{-1}Z_1\rho) \\
&= \rho(\rho^{-1}Z_1^{-1}\rho) x_{\alpha_2}(v_1)x_{\beta}(v_2)Y(\rho^{-1}Z_1\rho) \\
&= \rho x_{\alpha_2}(v_1)x_{\beta}(v_2)Y.
\end{align*}
Arguing similarly we can now up to conjugacy eliminate $Y$ and this completes the proof. We emphasize once more that all the above equalities are considered modulo the central subgroup $x_{\alpha_2+\beta}(\cdot)$ of $B(F) \rtimes \langle \rho \rangle$. \hfill \qed

**Theorem 3.6.** Let $F$ be a separably closed field and let $G$ be a simple simply connected algebraic group or a simple adjoint algebraic group of type $D_4$. Let $\phi \in \text{Aut}(G)(F)$ be an outer automorphism of order 3 of $G$. There exists a maximal $F$-torus $T$ which is invariant under $\phi$. Moreover, if $\tau$ is another outer automorphism of order 3, there exists a conjugate of $\tau$ in $\text{Aut}(G)(F)$ which leaves the $F$-torus $T$ invariant.

**Proof.** The last claim follows from the fact that over a separably closed field two maximal tori in $G$ are always conjugate ([Bor56]). To show the existence of an invariant torus we treat the cases $\text{char } F \neq 3$ and $\text{char } F = 3$ separately. We may assume that $G$ is simply connected by Lemma 3.2. We keep the above notation. Let $H$ be the subgroup in $G$ provided by Proposition 3.3. By construction it is $\phi$-stable. Since $H'$ has no outer automorphisms of order 3 the restriction of $\phi$ to $H'$ is an inner automorphism of $H'$ given by an element $x \in H'$.

A) **Characteristic $F \neq 3$.**

Note that $\phi$ is a semi-simple automorphism of $G$ in characteristic different from 3, hence $x$ is also semi-simple and therefore $x$ is contained in a maximal torus, say $S'$, in $H'$. By our construction we have $\dim S' = 2$ and $\dim S = 2$. 

Documenta Mathematica 18 (2013) 413–468
and this implies that the torus $T = S \cdot S'$ is maximal in $G$ and stable with respect to $\phi$ (because so are $S$ and $S'$).

**B) Characteristic $F = 3$.**

We keep the notation used above. Since $x$ has order 3 it is unipotent. Therefore there are two possibilities for its Jordan normal form.

We first assume that

$$
\begin{bmatrix}
1 & 1 & 0 \\
0 & 1 & 1 \\
0 & 0 & 1
\end{bmatrix}
$$

Let $\{e_1, e_2, e_3\}$ be the basis of the vector space over $F$ in which $x$ has form (3.7). Let $S' \subset H'$ be a maximal torus in $H'$ whose three weight subspaces are spanned by $e_1 + e_2$, $2e_1 + e_2$, $2e_1 + 2e_2 + e_3$. One easily checks that $S'$ is stable with respect to conjugation given by $x$. As above we then get that the maximal torus $T = S \cdot S'$ in $G$ is invariant with respect to $\phi$.

We next assume that $x$ is of the form

$$
x = x_{\alpha_2}(1) = \begin{bmatrix}
1 & 1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
$$

Let $S'$ be the corresponding diagonal torus in $H' = \text{SL}_3$ and let $T = S \cdot S'$. Choose a graph automorphism $\sigma$ of $G$ such that it acts trivially on $H' = G_{\alpha_2, \beta}$ and the images of $\phi$ and $\sigma$ with respect to $G \times \mathfrak{S}_3 \to \mathfrak{S}_3$ are equal. Let $\psi = \phi \circ (\sigma x)^{-1}$. It is an inner automorphism of $G$ acting trivially on $H'$ and hence on $S'$. It follows that $\psi$ stabilizes $C_G(S') = T$. Note that the last equality follows from the fact that in general case $C_G(S')$ is a reductive group generated by $T$ and root subgroups $U_\gamma$, such that $\gamma$ is orthogonal to $\alpha_2$ and $\beta$ and in case $D_4$ there are no roots orthogonal to $\alpha_2, \beta$. Thus we showed that $\psi$ is an inner conjugation in $G$ given by an element say $y$ which belongs to $N_G(T)(F)$. By our construction $y$ commutes with $S'$ and hence with its generators $h_{\alpha_2}(u)$ and $h_{\beta}(u)$. In view of (2.4) we conclude that the image $\hat{y}$ of $y$ in the Weyl group $W = N_G(T)/T$ acts trivially on the roots $\alpha_2, \beta$. One checks that in the Weyl group of type $D_4$ none of the elements acts trivially on two roots whose scalar product is $-1$. It follows $\hat{y} = 1$ implying $y \in T$. Thus we showed that $\phi = y\sigma x$ where $y \in T(F)$. By (2.3) we can write $y$ in the form $y = h_{\alpha_2}(u_2)h_{\alpha_1}(u_1)h_{\alpha_2}(u_3)h_{\alpha_4}(u_4)$ where $u_i \in F^\times$. Since $x$ commutes with $\sigma$ it is easy to see that the condition that $\phi$ has order 3 implies $h_{\alpha_1}(u_1)h_{\alpha_2}(u_3)h_{\alpha_4}(u_4)\sigma$ also has order 3 and $h_{\alpha_2}(u_2)^3 = 1$. The latter of course implies that $u_2 = 1$. Then arguing as in Lemma 3.4 we may write $h_{\alpha_1}(u_1)h_{\alpha_2}(u_3)h_{\alpha_4}(u_4)\sigma$ in the form $t\sigma t^{-1}$ for some element $t \in T(F)$. It follows $\phi = t\sigma t^{-1} x$ or $t^{-1}\phi t = \sigma(t^{-1}xt)$. Note that $\tilde{x} = t^{-1}xt \in U_{\alpha_2}$. Let $B \subset G$ be the corresponding Borel subgroup in $G$. By Lemma 3.4 the element $\sigma \tilde{x}$ is conjugate in $B(F) \rtimes \mathbb{Z}/3\mathbb{Z}$ to an element of the form $\sigma x'$ where $x' = x_{\alpha_2}(u_1)x_{\beta}(u_2)x_{\alpha_2+\beta}(u_3)$ and $u_1, u_2$ are non-zero elements in $F$. The Jordan
normal form of such unipotent element is of the shape (3.7) and this reduces the proof to the previous case. □

Corollary 3.8. Let $G$ be a simple simply connected algebraic group or a simple adjoint algebraic group of type $\text{D}_4$ over an arbitrary field $F$ and let $\phi$ be a trialitarian automorphism of $G$ over $F$. There exists a finite separable field extension $\tilde{F}$ of $F$ such that over $\tilde{F}$ there is a split maximal torus $T$ which is invariant under $\phi$. Moreover, if $\tau$ is another trialitarian automorphism of $G$ over $F$, there exists a conjugate of $\tau$ in the automorphism group of $G$ over a finite separable field extension of $F$ which leaves the torus $T$ invariant.

Let $G$ be split over $F$ and $T \subset G$ be a split maximal torus over $F$. We denote the group of automorphisms of $G$ which leave the torus $T$ invariant by $\text{Aut}(G \supset T)$. Let $\rho \in \text{Aut}(G \supset T)(F)$ be a fixed trialitarian automorphism of $G$, for example the graph automorphism of $G$ described in the introduction.

The normalizer $N$ of $T$ in $G$ is also invariant under $\rho$ and $\rho$ induces a well-defined action $\rho$ on $N/T$, which is the Weyl group $W$ of $G$. This action is not inner. The group $W$ also admits a group of outer automorphisms isomorphic to $S_3$ and we still call trialitarian the outer automorphisms of $W$ of order 3 (see [Ban69], [Fra01] or [FH03] for automorphism groups of Weyl groups).

Proposition 3.9. (i) Any trialitarian automorphism $\alpha \in \text{Aut}(G)(F)$ leaving $T$ invariant induces a trialitarian automorphism $\alpha$ of $W$.

(ii) If two trialitarian automorphisms $\alpha$ and $\beta$ of $G$ over $F$ leaving the same torus $T$ invariant satisfy $\alpha = \beta$ in $\text{Aut}(W)$, then $\alpha = \text{Int}(t) \circ \beta$ for some element $t \in T(F)$.

Proof. We may assume that $G$ is adjoint and we may view trialitarian automorphisms as elements of $G \rtimes S_3$. In particular trialitarian automorphisms of $G$ which leave $T$ invariant are represented by elements of $N \rtimes S_3$. Let now $\alpha$ be represented by an element $\alpha_0 \in (N \rtimes S_3)(F)$. Let $\alpha_0'$ be the class of $\alpha_0$ in $(W \rtimes S_3)(F) = W \rtimes S_3$ according to the last map in the exact sequence

$$1 \rightarrow T \rightarrow N \rtimes S_3 \rightarrow W \rtimes S_3 \rightarrow 1.$$ (3.10)

Let $Z(W) = \mathbb{Z}/2\mathbb{Z}$ be the center of $W$. The class of the automorphism $\overline{\alpha}$ of $W$ induced by $\alpha$ is the class $\overline{\alpha} = \overline{\alpha_0'}$ of $\alpha_0'$ in $\text{Aut}(W) \subset W/Z(W) \rtimes S_3$, hence Claim (i). For Claim (ii), the image of an element $\alpha \circ \beta^{-1}$ in $W$ induces the trivial automorphism of $W$. Since the center of $W$ has order 2 and $\alpha$, $\beta$ have order 3 this image is trivial and this implies $\alpha = \text{Int}(t) \circ \beta$ for some $t \in T(F)$. □

4. Trialitarian automorphisms and symmetric compositions

In the following sections, we recall a construction of trialitarian automorphisms given in [KMRT98, §35.B], [CKT12, Th. 4.6], and we construct explicitly invariant tori for some of these automorphisms.
Let \((V,q)\) be a quadratic space over \(F\), i.e., \(V\) is a finite-dimensional vector space over \(F\) and \(q: V \to F\) is a quadratic form. We always assume that \(q\) is nonsingular, in the sense that the polar bilinear form \(b_q\) defined by
\[
b_q(x, y) = q(x + y) - q(x) - q(y) \quad \text{for } x, y \in V
\]
has radical \(\{0\}\). We also assume throughout that \(\dim V\) is even.

Let \(\GO(q)\) be the \(F\)-algebraic group of similarities of \((V,q)\), whose group of rational points \(\GO(q)(F)\) consists of linear maps \(f: V \to V\) for which there exists a scalar \(\mu(f) \in F^\times\), called the multiplier of \(f\), such that
\[
q(f(x)) = \mu(f)q(x) \quad \text{for all } x \in V.
\]

Let also \(O(q)\) be the \(F\)-algebraic group of isometries of \((V,q)\), i.e., the kernel of the multiplier map \(\mu: \GO(q) \to G_m\). The center of \(\GO(q)\) is the multiplicative group \(G_m\), whose rational points are viewed as homotheties. For \(f \in \GO(q)(F)\), we let \([f]\) be the image of \(f\) in \(\PGO(q)(F) = \GO(q)(F)/G_m(F)\). For simplicity, we write
\[
\GO(q) = \GO(q)(F) \quad \text{and} \quad \PGO(q) = \PGO(q)(F) = \GO(q)/F^\times.
\]

Let \(C(V,q)\) be the Clifford algebra of the quadratic space \((V,q)\) and let \(C_0(V,q)\) be the even Clifford algebra. We let \(\sigma\) be the canonical involution of \(C(V,q)\), such that \(\sigma(x) = x\) for \(x \in V\), and use the same notation for its restriction to \(C_0(V,q)\). Every similarity \(f \in \GO(q)\) induces an automorphism \(C_0(f)\) of \((C_0(V,q),\sigma)\) such that
\[
C_0(f)(xy) = \mu(f)^{-1}f(x)f(y) \quad \text{for } x, y \in V,
\]
see [KMRT98, (13.1)]. This automorphism depends only on the image \([f] = fF^\times\) of \(f\) in \(\PGO(q)\), and we shall use the notation \(C_0[f]\) for \(C_0(f)\). The similarity \(f\) is proper if \(C_0[f]\) fixes the center of \(C_0(V,q)\) and improper if it induces a nontrivial automorphism of the center of \(C_0(V,q)\) (see [KMRT98, (13.2)]).

Proper similarities define an algebraic subgroup \(\GO^+(q)\) in \(\GO(q)\), and we let \(\PGO^+(q) = \GO^+(q)/G_m\), a subgroup of \(\PGO(q)\). The groups \(\GO^+(q)\) and \(\PGO^+(q)\) are the connected components of the identity in \(\GO(q)\) and \(\PGO(q)\) respectively, see [KMRT98, §23.B]. We write \(O^+(q)\) for the algebraic group of proper isometries of \((V,q)\).

The \(F\)-rational points of the \(F\)-algebraic group \(\Spin(q)\) are given by
\[
\Spin(q)(F) = \Spin(q) = \{c \in C_0(V,q)^\times \mid cVc^{-1} \subset V \quad \text{and} \quad c\sigma(c) = 1\},
\]
see for example [KMRT98, §35.C]. For any element \(c \in \Spin(q)\) the linear map \(x \mapsto cxc^{-1}, x \in V\), is a proper similitude of \((V,q)\). Thus there exists a morphism of algebraic groups \(\pi: \Spin(q) \to \PGO^+(q)\). In the next proposition we collect known results about the algebraic groups \(\Spin(q)\) and \(\PGO^+(q)\), see for example [KMRT98, 26.A].

**Proposition 4.2.** Let \((V,q)\) be a quadratic space and let \(\dim V = 2n\) with \(n \equiv 0 \pmod{2}\).
(i) The algebraic group $\text{Spin}(q)$ is simple, simply connected of type $D_n$ and its center is isomorphic to $\mu_2^2 = \mu_2 \times \mu_2$, with $\mu_2(F) = \{\pm 1\}$.

(ii) The algebraic group $\text{PGO}^+(q)$ is simple, adjoint of type $D_n$.

(iii) The sequence of algebraic groups

$$1 \to \mu_2^2 \to \text{Spin}(q) \xrightarrow{\eta} \text{PGO}^+(q) \to 1$$

is exact.

Following [KMRT98, §35.B] or [CKT12, §4] we next recall how trialitarian automorphisms can be generated with the help of symmetric compositions, which we define next, following [KMRT98, §34] or [CKT12, §3].

**Definition 4.3.** A symmetric composition on a nonsingular quadratic space $(S, n)$ is a bilinear map $*: S \times S \to S$ such that for all $x, y, z \in S$

1. $n(x \ast y) = n(x)n(y)$,
2. $b_n(x \ast y, z) = b_n(x, y \ast z)$,
3. $x \ast (y \ast x) = n(x)y = (x \ast y) \ast x$.

If $*$ is a symmetric composition on $(S, n)$, the triple $(S, *, n)$ is called a symmetric composition algebra. The composition $*$ is its multiplication.

Symmetric composition algebras exist in dimension 2, 4, and 8. Their norms are Pfister forms. From now on, we restrict to dimension 8.

**Theorem 4.4.** Let $(S, *, n)$ be an 8-dimensional symmetric composition algebra. Let $f$ be a similitude of $n$ with multiplier $\mu(f)$.

(i) If $f$ is proper there exist proper similitudes $f_1, f_2$ of $n$ such that for all $x, y \in S$

$$\mu(f)^{-1}f(x \ast y) = f_2(x) \ast f_1(y)$$

$$\mu(f_1)^{-1}f_1(x \ast y) = f(x) \ast f_2(y)$$

$$\mu(f_2)^{-1}f_2(x \ast y) = f_1(x) \ast f(y).$$

(ii) If $f$ is improper there exist improper similitudes $f_1, f_2$ of $n$ such that for all $x, y \in S$

$$\mu(f)^{-1}f(x \ast y) = f_2(y) \ast f_1(x)$$

$$\mu(f_1)^{-1}f_1(x \ast y) = f(y) \ast f_2(x)$$

$$\mu(f_2)^{-1}f_2(x \ast y) = f_1(y) \ast f(x).$$

The pair $(f_1, f_2)$ is determined by $f$ up to a factor $(\mu, \mu^{-1})$, $\mu \in F^\times$, and we have $\mu(f_1)\mu(f_2) = 1$. Furthermore any of the three formulas in (i) (resp. (ii)) implies the two others.

For a proof, see [KMRT98, (35.4)] or [CKT12, Th. 4.5].

---

3The symmetric compositions considered in [CKT12] are slightly more general; the ones we use here are referred to as normalized in [CKT12].
In view of Theorem 4.4, the elements $[f_1], [f_2]$ in $\text{PGO}^+(n)(F)$ are uniquely determined by $[f]$. Thus they give rise to well-defined maps

$$\rho_* : \text{PGO}^+(n)(F) \to \text{PGO}^+(n)(F), \quad [f] \mapsto [f_2],$$

$$\hat{\rho}_* : \text{PGO}^+(n)(F) \to \text{PGO}^+(n)(F), \quad [f] \mapsto [f_1].$$

**Theorem 4.5.** The mappings $\rho_*$ and $\hat{\rho}_*$ are outer automorphisms over $F$ of order 3 of $\text{PGO}^+(n)$, and $\hat{\rho}_* = \rho_2^*.$

**Proof.** See [KMRT98, (35.6)]. □

The algebraic group $\text{Spin}(n)$ can be described with the help of a symmetric composition $\star$ on $(S,n)$:

**Proposition 4.6.** Let $(S,\star,n)$ be a symmetric composition algebra with norm $n$. Then

$$\text{Spin}(n)(F) = \{ (f,f_1,f_2) \mid f_i \in \mathcal{O}(n)(F), f(x \star y) = f_2(x) \star f_1(y), x,y \in S \}.$$  

Moreover any of the three relations

$$f(x \star y) = f_2(x) \star f_1(y)$$

$$f_1(x \star y) = f(x) \star f_2(y)$$

$$f_2(x \star y) = f_1(x) \star f(y)$$

implies the two others.

**Proof.** See [KMRT98, (35.2)] for a proof in characteristic different from 2 and [KT13] for a proof in any characteristic. □

We have an obvious trialitarian automorphism $\rho_*$ of $\text{Spin}(n)$:

$$\rho_* : (f,f_1,f_2) \mapsto (f_2,f,f_1)$$

and properties similar to those for $\text{PGO}^+(n)$ hold.

Viewing $\mu_3^2$ as kernel of the multiplication map

$$p : \mu_3^2 \to \mu_2, \quad p(\varepsilon_1,\varepsilon_2,\varepsilon_3) = \varepsilon_1\varepsilon_2\varepsilon_3,$$

we get a natural $\mathfrak{A}_3$-action on the center $\mu_3^2$ of $\text{Spin}(n)$, compatible with the trialitarian action on $\text{Spin}(n)$ and the sequence

$$1 \to \mu_2^2 \to \text{Spin}(n) \to \text{PGO}^+(n) \to 1$$

is $\mathfrak{A}_3$-equivariant (see [KMRT98, (35.13)]). Here $\mathfrak{A}_3 \subseteq \mathfrak{S}_3$ is the subgroup of even permutations. In particular the trialitarian action on $\text{Spin}(n)$ is a lift of the trialitarian action on $\text{PGO}^+(n)$.

Isomorphisms of symmetric compositions are defined in the obvious way. The trialitarian automorphisms associated to isomorphic symmetric compositions are conjugate; more precisely, we have:

**Lemma 4.7.** Let $\phi : (S,\diamond,n) \to (S,\star,n)$ be an isomorphism of symmetric composition algebras. Then

$$\rho_* = \text{Int}(\phi) \circ \rho_0 \circ \text{Int}(\phi)^{-1}.$$
Proof. See [CKT12, Proposition 6.1]. \[\square\]

The main result of [CKT12] is the following:

**Theorem 4.8.** Let \((S, n)\) be a 3-Pfister quadratic space over a field \(F\). The assignment \(* \mapsto \rho_*\) defines a one-to-one correspondence between isomorphism classes of symmetric compositions on \((S, n)\) and conjugacy classes over \(F\) of trialitarian automorphisms of \(\text{PGO}^+(n)\) defined over \(F\).

**Proof.** This follows from Theorems 5.8 and 6.4 of [CKT12]. \[\square\]

Automorphisms of order 3 of a given symmetric composition lead to new symmetric compositions by “twisting”:

**Proposition 4.9.** Let \((S, \star, n)\) be a symmetric composition algebra and let \(\phi\) be an automorphism of order 3 of \((S, \star, n)\).

(i) The multiplication 
\[
(\xi, \eta) \mapsto \xi \star \phi \eta = \phi(\xi) \star \phi^2(\eta), \quad \text{for } \xi, \eta \in S
\]
defines a symmetric composition on the quadratic space \((S, n)\).

(ii) \(\rho_{\star \phi} = \text{Int}(\phi^{-1}) \circ \rho_\star\).

**Proof.** See [Pet69] for the first claim and [CKT12, Lemma 5.2] for the second. \[\square\]

The symmetric composition \(*_\phi\) is called the (Petersson) twist of \(*\).

5. **Zorn matrices**

In this section we use Zorn’s nice description of the split octonion algebra in [Zor30] to give two examples of 8-dimensional symmetric compositions. The associated trialitarian automorphisms play a fundamental rôle in this work.

The **Zorn matrix algebra** is defined as follows. Let \(\bullet\) be the usual scalar product on the 3-dimensional space \(F^3\) and let \(\times\) the vector product: for vectors \(\vec{a} = (a_1, a_2, a_3)\) and \(\vec{b} = (b_1, b_2, b_3) \in F^3\), we have \(\vec{a} \bullet \vec{b} = a_1b_1 + a_2b_2 + a_3b_3\) and \(\vec{a} \times \vec{b} = (a_2b_3 - a_3b_2, a_3b_1 - a_1b_3, a_1b_2 - a_2b_1)\). The Zorn algebra is the set of matrices
\[
C = \left\{ \begin{pmatrix} \alpha & \vec{a} \\ \vec{b} & \beta \end{pmatrix} \big| \alpha, \beta \in F, \, \vec{a}, \vec{b} \in F^3 \right\}
\]
with the product
\[
(5.1) \quad \begin{pmatrix} \alpha & \vec{a} \\ \vec{b} & \beta \end{pmatrix} \cdot \begin{pmatrix} \gamma & \vec{c} \\ \vec{d} & \delta \end{pmatrix} = \begin{pmatrix} \alpha\gamma + \vec{a} \bullet \vec{d} & \alpha \vec{c} + \delta \vec{a} - \vec{b} \times \vec{d} \\ \gamma \vec{b} + \beta \vec{d} + \vec{a} \times \vec{c} & \beta \delta + \vec{b} \bullet \vec{c} \end{pmatrix},
\]
the norm
\[
n(\begin{pmatrix} \alpha & \vec{a} \\ \vec{b} & \beta \end{pmatrix}) = \alpha \beta - \vec{a} \bullet \vec{b},
\]
and the conjugation
\[
\overline{(\begin{pmatrix} \alpha & \vec{a} \\ \vec{b} & \beta \end{pmatrix})} = \begin{pmatrix} \beta & -\vec{a} \\ -\vec{b} & \alpha \end{pmatrix}.
\]

**Documenta Mathematica** 18 (2013) 413–468
which is such that $\xi \cdot \overline{\xi} = \xi \cdot \xi = n(\xi)$ for all $\xi \in C$ (see [Zor30, p. 144]). The element $1 = \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right)$ is an identity element for the product. One checks that the norm is multiplicative:

(5.2) $n(\xi \cdot \eta) = n(\xi)n(\eta)$ for all $\xi, \eta$ in $C$.

Thus $(C, \cdot, n)$ is an 8-dimensional composition algebra with identity. Since the norm $n$ is obviously a hyperbolic form, $(C, \cdot, n)$ is a split octonion algebra.

Let $\{\vec{a}_1, \vec{a}_2, \vec{a}_3\}$ be the standard basis of $F^3$. The elements

(5.3) $e_1 = \left( \begin{array}{cc} 1 & 0 \\ 0 & 0 \end{array} \right)$, $f_1 = \left( \begin{array}{cc} 0 & 0 \\ 0 & 1 \end{array} \right)$, $u_i = \left( \begin{array}{cc} 0 & -\vec{a}_i \\ \vec{a}_i & 0 \end{array} \right)$, $v_i = \left( \begin{array}{cc} 0 & \vec{a}_i \\ \vec{a}_i & 0 \end{array} \right)$, $i = 1, 2, 3$, form a hyperbolic basis, called the canonical basis of the Zorn algebra $(C, \cdot, n)$.

We have $e_1 = f_1$, and $u_i = -u_i$, $v_i = -v_i$ for $i = 1, 2, 3$.

Next we associate to $(C, \cdot, n)$ a symmetric composition. More generally, let $(H, \cdot, n)$ be a Hurwitz algebra (i.e., a quadratic algebra, a quaternion algebra or an octonion algebra) with conjugation $x \mapsto \overline{x}$, $x \in H$.

**Lemma 5.4.** Setting $x \diamond y = x \cdot y$ we get a symmetric composition $(H, \diamond, n)$.

**Proof.** See for example [KMRT98, §34A].

We call $(H, \diamond, n)$ the para-Hurwitz algebra (resp. para-quadratic, para-quaternion or para-octonion algebra) associated with $H$. Applying the same construction to the Zorn algebra, we obtain the para-Zorn algebra with multiplication

(5.5) $\left( \begin{array}{cc} \alpha & \vec{a} \\ \vec{b} & \beta \end{array} \right) \circ \left( \begin{array}{cc} \gamma & \vec{c} \\ \vec{d} & \delta \end{array} \right) = \left( \begin{array}{cc} \beta \vec{d} + \vec{a} \bullet \vec{d} & -\beta \vec{c} - \gamma \vec{a} - \vec{b} \times \vec{d} \\ -\delta \vec{d} - \alpha \vec{d} + \vec{a} \times \vec{c} & \alpha \gamma + \vec{b} \bullet \vec{c} \end{array} \right)$.

As we shall see in Remark 8.11 the trialitarian automorphism associated to the para-Zorn algebra is conjugate to the graph automorphism described in the introduction.

The group $\text{GL}_3$ acts on the vector space $C$ of Zorn matrices by

(5.6) $s_g \left( \begin{array}{cc} \alpha & \vec{a} \\ \vec{b} & \beta \end{array} \right) = \left( \begin{array}{cc} \alpha g^2(\vec{b}) & g(\vec{a}) \\ g^2(\vec{b}) & \beta \end{array} \right)$,

where $g \in \text{GL}_3(F)$ and $g^4 = (g^{-1})^4$.

**Proposition 5.7.** (i) The mappings $s_g$ for $g \in \text{SL}_3(F)$ are automorphisms of the para-Zorn algebra $(C, \diamond, n)$.

(ii) The mappings $s_g$ for $g \in \text{GL}_3(F)$ are isometries of $(C, n)$.

---

4Zorn’s definition is different, but isomorphic under the map $(\alpha \vec{a} \vec{b} \beta) \mapsto (\alpha \vec{a} \vec{b} \beta)$. 

---

**Documenta Mathematica 18 (2013) 413–468**
Proof. Let \( g \in \text{GL}_3(F) \). For \( \vec{x}, \vec{y} \in F^3 \) we have \( g(\vec{x}) \cdot \vec{y} = \vec{x} \cdot g^t(\vec{y}) \), hence
\[
(5.8) \quad g(\vec{x}) \cdot g^t(\vec{y}) = \vec{x} \cdot \vec{y}.
\]

This readily implies (ii). To prove (i), observe that \( \vec{x} \times \vec{y} \) is characterized by the condition that for all \( \vec{z} \in F^3 \)
\[
[(\vec{x} \times \vec{y}) \cdot \vec{z}] \vec{a}_1 \wedge \vec{a}_2 \wedge \vec{a}_3 = \vec{x} \wedge \vec{y} \wedge \vec{z} \quad \text{in } \bigwedge^3 F^3.
\]

For all \( \vec{x}, \vec{y}, \vec{z} \in F^3 \) we have
\[
(\det g) \vec{x} \wedge \vec{y} \wedge \vec{z} = g(\vec{x}) \wedge g(\vec{y}) \wedge g(\vec{z}),
\]

hence
\[
(\det g) (\vec{x} \times \vec{y}) \cdot \vec{z} = (g(\vec{x}) \times g(\vec{y})) \cdot g(\vec{z}) = g^t (g(\vec{x}) \times g(\vec{y})) \cdot \vec{z}.
\]

Since these equations hold for all \( \vec{z} \in F^3 \) it follows that
\[
(\det g) (\vec{x} \times \vec{y} = g^t (g(\vec{x}) \times g(\vec{y})) \quad \text{for all } \vec{x}, \vec{y} \in F^3,
\]

hence
\[
(5.9) \quad (\det g) g^t(\vec{x} \times \vec{y}) = g(\vec{x}) \times g(\vec{y}) \quad \text{for all } \vec{x}, \vec{y} \in F^3.
\]

A straightforward computation then yields (i). \( \square \)

Let \( \pi \) be the cyclic permutation of the standard basis vectors \( \pi: \vec{a}_1 \mapsto \vec{a}_2 \mapsto \vec{a}_3 \mapsto \vec{a}_1 \), extended by linearity to \( F^3 \), i.e.,
\[
(5.10) \quad \pi = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \in \text{SL}_3(F).
\]

The symmetric composition algebra \((C, \circ_\pi, n)\) obtained by twisting the parazorn algebra \((C, \circ, n)\) with the automorphism \( s_\pi \) is called the split Okubo algebra. We let \( \triangle \) denote its multiplication. Thus
\[
\begin{pmatrix} \alpha & \vec{a} \\ \beta & \vec{b} \end{pmatrix} \triangle \begin{pmatrix} \gamma & \vec{c} \\ \delta & \vec{d} \end{pmatrix} = \begin{pmatrix} \beta \delta + \pi(\vec{a}) \cdot \pi^2(\vec{d}) & -\beta \pi^2(\vec{c}) - \gamma \pi(\vec{a}) - \pi(\vec{b}) \times \pi^2(\vec{d}) \\ -\delta \pi(\vec{b}) - \alpha \pi^2(\vec{d}) + \pi(\vec{a}) \times \pi^2(\vec{c}) & \alpha \gamma + \pi(\vec{b}) \cdot \pi^2(\vec{c}) \end{pmatrix}.
\]

The multiplication table of \( \triangle \) with respect to the canonical basis (5.3) is

---

\(^5\)Okubo ([Oku78]) gave a different description of this algebra, valid over fields of characteristic not 3, see also Proposition 8.5 in this paper.
If the field $F$ contains a primitive cube root $\omega$ of 1 (so that in particular $F$ has characteristic different from 3), there is another way to twist the multiplication of the para-Zorn algebra to get the split Okubo algebra: let $\omega = \text{Diag}(1, \omega, \omega^2) \in \text{SL}_3(F)$ and let $s_\omega$ be the corresponding automorphism of $(C, \circ, n)$, see Proposition 5.7. We may then consider the Petersson twist $\triangledown = \circ s_\omega$. The next lemma shows that the symmetric composition $\triangledown$ is isomorphic to $\triangle$.

**Lemma 5.12.** Let

$$g = \frac{\omega - \omega^2}{3} \begin{pmatrix} 1 & 1 & 1 \\ -1 & -\omega & -\omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix} \in \text{SL}_3(F).$$

The isometry $s_g$ of $(C, n)$ is an isomorphism of symmetric compositions $\triangle \sim \triangledown$.

**Proof.** The matrix $g$ satisfies $\omega g = g, \pi$, hence also $\omega^2 g^2 = g^2 \pi^2 = g^2 \pi$. The lemma is then verified by straightforward computations, using the identities (5.8), (5.9).

By contrast, the para-Zorn multiplication $\circ$ and the split Okubo multiplication $\triangle$ are not isomorphic, even if the base field $F$ is algebraically closed. This can be seen directly because the para-Zorn algebra contains a para-unit (see Definition 9.1 below), whereas the split Okubo algebra does not.

### 6. A Maximal Torus for $\text{PGO}_8^+$ and $\text{Spin}_8$

Let $G$ denote one of the algebraic groups $\text{PGO}_8^+$ or $\text{Spin}_8$. In view of Theorem 3.6, to classify triallitarian automorphisms over a separably closed field, we may fix a maximal torus $T$ and consider only triallitarian automorphisms of $G$ which leave $T$ invariant. We now describe a special maximal split torus which is invariant under the triallitarian automorphisms associated to the para-Zorn algebra $(C, \circ, n)$ and the split Okubo algebra $(C, \triangle, n)$.

Consider the following torus

$$T_0 = G_m^5 = G_m^2 \times \text{Diag}_3$$

**References:**

Chernousov, Elduque, Knus, Tignol

**Documenta Mathematica** 18 (2013) 413–468
where $\text{Diag}_3$ is the torus of diagonal matrices in $\text{GL}_3$. The torus $T_0$ acts by similitudes on the quadratic space $(C,n)$ of Zorn matrices as follows:

\[(6.2) \quad (\lambda, \mu, t) \oplus \left( \begin{array}{cc} \alpha & \tilde{a} \\ \beta & \tilde{b} \end{array} \right) = \left( \begin{array}{cc} \lambda \alpha & \lambda \mu t^{-1} \tilde{a} \\ \mu \beta & \mu \end{array} \right).\]

The group $T_0$ is a maximal torus of $\text{GO}^+_4 (= \text{GO}^+(n))$, and $G_m$ diagonally embedded into $T_0$ is the center of $\text{GO}^+_4$. Thus $T_0/G_m$ is a maximal torus of $\text{PGO}^+_4$, which we denote by $T$. For $(\lambda, \mu, t) \in T_0(F)$, we write $[\lambda, \mu, t]$ for $[(\lambda, \mu, t)] \in T(F)$. We compute the action on $T$ of the trialitarian automorphism $\rho_0$ associated to the para-Zorn algebra $(C, \diamond, n)$:

**Lemma 6.3.** Let $(\lambda, \mu, t) \in T_0(F)$. If $\lambda', \mu', \lambda'', \mu'' \in F^\times$ are such that

\[(6.4) \quad \mu' \mu'' = \lambda, \quad \lambda' \lambda'' = \mu, \quad \text{and} \quad \lambda' \lambda'' = (\det t)(\lambda \mu)^{-1},\]

then for $\xi, \eta \in C$, we have

\[(\lambda, \mu, t) \circ (\xi \circ \eta) = ((\lambda', \mu', \mu''^{-1} t) \circ \xi) \circ ((\lambda'', \mu'', \lambda' t) \circ \eta);\]

hence

\[\rho_0[\lambda, \mu, t] = [\lambda', \mu', \mu''^{-1} t] \quad \text{and} \quad \rho_0^2[\lambda, \mu, t] = [\lambda'', \mu'', \lambda^{-1} t].\]

The lemma is verified by a straightforward computation. It shows that the torus $T$ is invariant under $\rho_0$, provided a solution to (6.4) exists for all $(\lambda, \mu, t) \in T_0(F)$. This is indeed the case:

**Proposition 6.5.** For $(\lambda, \mu, t) \in T_0(F)$,

\[\rho_0[\lambda, \mu, t] = [\det t, \lambda^2, \lambda \mu t] = [(\lambda \mu)^{-1} \det t, \lambda, t]\]

and

\[\rho_0^2[\lambda, \mu, t] = [\mu(\det t)^{-1}, (\lambda \mu)^{-1}, (\det t)^{-1} t] = [\mu, (\lambda \mu)^{-1} \det t, t].\]

**Proof.** Check that the equations (6.4) have the following solution:

\[\lambda' = \det t, \quad \mu' = \lambda^2, \quad \lambda'' = \mu(\det t)^{-1}, \quad \mu'' = (\lambda \mu)^{-1} \cdot \]

\[\square\]

We next show that the torus $T$ is also stable under the trialitarian automorphism $\rho_0$ associated to the split Okubo algebra $(C, \triangle)$. We recall that the multiplicity $\triangle$ is the Petersson twist $\otimes_{s_K}$ of the multiplication $\diamond$ by the automorphism $s_K$ of the para-Zorn algebra.

**Proposition 6.6.** For $(\lambda, \mu, t) \in T_0(F)$ we have

\[s_K^{-1} \circ (\lambda, \mu, t) \circ s_K = (\lambda, \mu, \pi^{-1} t \pi),\]

and

\[\rho_0[\lambda, \mu, t] = [(\lambda \mu)^{-1} \det t, \lambda, \pi^{-1} t \pi], \quad \rho_0^2[\lambda, \mu, t] = [\mu, (\lambda \mu)^{-1} \det t, \pi^{-2} t \pi^2].\]

**Proof.** The first equation is easily checked by direct computation. The others follow from Proposition 4.9 and Proposition 6.5. \[
\square\]
For the algebraic group $\text{Spin}_8$ we consider the torus
\[ T'_0 = G^4_m = G_m \times \text{Diag}_3 \]
as a subtorus of the torus $T_0$ defined in (6.1) through the embedding $(\lambda, t) \mapsto (\lambda, \lambda^{-1}, t)$. The torus $T'_0$ is a maximal torus of $O^+_{8}$ through the action $\otimes$ defined in (6.2). The spinor norm of the element $(\lambda, t)$ is the class of $\lambda \det t$ in $F^\times / F^\times 2$. Thus $(\lambda, t)$ lifts to an element in $\text{Spin}_8(F)$ if and only if the product $\lambda \det t$ is a square in $F$. By Lemma 6.3, the equation
\[ (\lambda, t) \otimes (\xi \odot \eta) = ((\lambda', t') \otimes \xi) \odot ((\lambda'', t'') \otimes \eta) \]
holds for all $\xi, \eta \in C$ if
\[ \lambda' \lambda'' = 1, \quad t' = \lambda'' t, \quad t'' = \lambda'^{-1} t, \quad \text{and} \quad \lambda' \lambda'^{-1} = \det t. \]
These equations imply
\[ \lambda'' = \lambda^{-1} \det t \quad \text{and} \quad \lambda'^{-1} = (\lambda \det t)^{-1}. \]
Thus the set of triples $((\lambda, t), (\lambda', t'), (\lambda'', t''))$ satisfying the above conditions is a maximal torus $\tilde{T}$ in $\text{Spin}_8$. For the twisted composition $\triangle$ we have
\[ \lambda \lambda'' = 1, \quad t' = \lambda'' t, \quad t'' = \lambda'^{-1} t, \quad \text{and} \quad \lambda' \lambda'^{-1} = \det t \]
instead of (6.7).

The natural coverings $\tilde{T} \to T'_0$ and $T'_0 \to T$ give natural embeddings of the character groups $X(T) \hookrightarrow X(T'_0) \hookrightarrow X(\tilde{T})$. Letting $t = \text{Diag}(t_1, t_2, t_3)$, we define characters $\varepsilon_1, \ldots, \varepsilon_4$ of $T'_0$ generating $X(T'_0)$ by
\[ \varepsilon_1 : (\lambda, t) \mapsto t_1, \quad \varepsilon_2 : (\lambda, t) \mapsto t_2^{-1}, \quad \varepsilon_3 : (\lambda, t) \mapsto t_3^{-1}, \quad \text{and} \quad \varepsilon_4 : (\lambda, t) \mapsto \lambda. \]
View each $\varepsilon_i$ as a character of $\tilde{T}$ through the embedding $X(T'_0) \hookrightarrow X(\tilde{T})$. Using additive notation, it follows from (6.8) that
\[ \rho_0(\varepsilon_1) = \frac{1}{2}(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 - \varepsilon_4) \]
\[ \rho_0(\varepsilon_2) = \frac{1}{2}(\varepsilon_1 + \varepsilon_2 - \varepsilon_3 + \varepsilon_4) \]
\[ \rho_0(\varepsilon_3) = \frac{1}{2}(\varepsilon_1 - \varepsilon_2 + \varepsilon_3 + \varepsilon_4) \]
\[ \rho_0(\varepsilon_4) = \frac{1}{2}(\varepsilon_1 - \varepsilon_2 - \varepsilon_3 + \varepsilon_4). \]
Formulas (6.10) imply that the action of $\rho_0$ on the vector space $\mathbb{R}^4 = X(\tilde{T}) \otimes_{\mathbb{Z}} \mathbb{R} = X(T'_0) \otimes_{\mathbb{Z}} \mathbb{R} = X(T) \otimes_{\mathbb{Z}} \mathbb{R}$ is given by the matrix
\[ R_\phi = \frac{1}{2} \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ -1 & 1 & 1 & -1 \end{pmatrix}. \]
In view of (6.9) the action of $\rho_\delta$ is given by

$$R_\delta = \frac{1}{2} \begin{pmatrix}
-1 & -1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
-1 & -1 & 1 & -1 \\
1 & 1 & 1 & -1
\end{pmatrix}. $$

Recall from [Bou81] that the simple roots of $\text{Spin}_8$ are

$$\alpha_1 = \varepsilon_1 - \varepsilon_2, \quad \alpha_2 = \varepsilon_2 - \varepsilon_3, \quad \alpha_3 = \varepsilon_3 - \varepsilon_4, \quad \text{and} \quad \alpha_4 = \varepsilon_3 + \varepsilon_4.$$ 

Let also $\tilde{\alpha} = \alpha_1 + 2\alpha_2 + \alpha_3 + \alpha_4$ be the highest root.

**Corollary 6.11.** The action of $\rho_\delta$ on $X(\tilde{T})$ permutes the simple roots as follows:

$$\rho_\delta : \alpha_1 \mapsto \alpha_3, \quad \alpha_3 \mapsto \alpha_4, \quad \alpha_4 \mapsto \alpha_1, \quad \alpha_2 \mapsto \alpha_2.$$ 

The action of $\rho_\delta$ is given by

$$\alpha_1 \mapsto \alpha_3 + \alpha_2, \quad \alpha_3 \mapsto \alpha_4 + \alpha_2, \quad \alpha_4 \mapsto \alpha_1 + \alpha_2, \quad \alpha_2 \mapsto -\tilde{\alpha}.$$

**Proof.** This is readily verified by computation using the matrices $R_\xi$ and $R_\delta$. 

**Remark 6.12.** Viewing the Weyl group $W$ of $\text{Spin}_8$ as the subgroup of the real orthogonal group $O_4(\mathbb{R})$ generated by the reflections with respect to the roots $\alpha_1, \alpha_2, \alpha_3, \alpha_4$, we conclude from the above discussion that the trialitarian automorphism $\overrightarrow{\rho}$ (resp. $\overleftarrow{\rho}$) of $W$ induced by $\rho_\delta$ (resp. $\rho_\Delta$) is given by conjugation in $O_4(\mathbb{R})$ by the matrix $R_\xi$ (resp. $R_\Delta$). In particular the action $\overrightarrow{\rho}$ induced by the graph automorphism $\rho$ (see the introduction) is the same as $\overrightarrow{\rho}$.

7. Trialitarian Automorphisms of $\text{PGO}_8^+$

In this section we show that every trialitarian automorphism of $\text{PGO}_8^+$ over an algebraically closed field is conjugate to either $\rho_\delta$ or $\rho_\Delta$, which we call the standard trialitarian automorphisms.

We denote by $\text{Aut}(\text{PGO}_8^+ \supset T)$ the subgroup of $\text{Aut}(\text{PGO}_8^+)$ consisting of automorphisms which map the maximal split torus $T$ introduced in Section 6 to itself. It follows from Theorem 3.6 that every trialitarian automorphism of $\text{PGO}_8^+$ is conjugate over a separable closure to an automorphism which belongs to $\text{Aut}(\text{PGO}_8^+ \supset T)$. Let $N_0 \subset \text{GO}_8^+$ be the normalizer of the torus $T_0$ (see (6.1)) and let $N = N_0 / G_m \subset \text{PGO}_8^+$. Let further

$$W = N_0 / T_0 = N / T$$

be the Weyl group of $\text{PGO}_8^+$. For $\alpha \in \text{Aut}(\text{PGO}_8^+ \supset T)(F)$, we have obviously $\alpha(N) = N$, hence $\alpha$ induces an automorphism $\overrightarrow{\alpha} \in \text{Aut}(W)$ defined by

$$\overrightarrow{\alpha}([g] \cdot T) = \alpha([g]) \cdot T \quad \text{for} \ g \in N_0.$$

In particular, for $g \in N_0(F)$, we have $\text{Int} \ (\overrightarrow{[g]}) \in \text{Aut}(\text{PGO}_8^+ \supset T)(F)$, and

$$\text{Int} \ (\overrightarrow{[g]}) = \text{Int}(gT_0).$$

\[\text{We could as well have discussed the case of Spin}_n.\]
By Proposition 3.9, $\overline{\rho}_c$ and $\overline{\rho}_d$ are outer automorphisms of order 3 of $W$.

**Proposition 7.1.** Every outer automorphism of order 3 of $W$ is conjugate in $\text{Aut}(W)$ to exactly one of $\overline{\rho}_c$ or $\overline{\rho}_d \in \text{Aut}(W)$.

**Proof.** This is well-known; see for instance [KT10, Proposition 5.8] or [KT12, Theorem 5.11].

**Proposition 7.2.** Let $F$ be an arbitrary field and $\phi \in \text{Aut}(\text{PGO}^+_8(F))$ be a trialitarian automorphism which admits an invariant maximal split torus over $F$. Then $\phi$ is conjugate in $\text{Aut}(\text{PGO}^+_8)(F)$ to an automorphism $\beta \in \text{Aut}(\text{PGO}^+_8 \supset T)(F)$ such that $\overline{\beta} = \overline{\rho}_c$ or $\overline{\rho}_d$.

**Proof.** Two maximal split tori in $\text{PGO}^+_8$ are conjugate over $F$. Thus $\phi$ is conjugate to a trialitarian automorphism $\beta \in \text{Aut}(\text{PGO}^+_8 \supset T)(F)$. Its image $\overline{\beta} \in \text{Aut}(W)$ is well defined and is also trialitarian. Note that $N(F) \to W$ is surjective (because $T$ is split) and therefore so is $N(F) \times \mathfrak{S}_3 \to \text{Aut}(W)$. By Proposition 7.1, one can find $g \in N(F) \times \mathfrak{S}_3 \subset \text{Aut}(\text{PGO}^+_8)(F)$ such that

$$\overline{\beta} = \text{Int}(gT) \circ \overline{\rho}_c \circ \text{Int}(gT)^{-1} \quad \text{or} \quad \overline{\beta} = \text{Int}(gT) \circ \overline{\rho}_d \circ \text{Int}(gT)^{-1}.$$  

Let $\beta_0 = \text{Int}([g])^{-1} \circ \beta \circ \text{Int}([g])$. Then $\beta_0$ is conjugate to $\beta$, and $\overline{\beta_0} = \overline{\rho}_c$ or $\overline{\rho}_d$.

From now on we only consider automorphisms $\beta \in \text{Aut}(\text{PGO}^+_8 \supset T)(F)$ such that $\overline{\beta} = \overline{\rho}_c$ or $\overline{\rho}_d$.

**Proposition 7.3.** Let $\beta \in \text{Aut}(\text{PGO}^+_8 \supset T)(F)$ be a trialitarian automorphism such that $\overline{\beta} = \overline{\rho}_d$. There exists an extension $\tilde{F} = F(\xi, \eta)$ of $F$, with $\xi^3 \in F^x$ and $\eta^3 \in F^x$, such that $\beta$ and $\rho_d$ are conjugate in $\text{Aut}(\text{PGO}^+_8)(\tilde{F})$.

**Proof.** Since $\overline{\beta} = \overline{\rho}_d$, we have $\beta \rho_d^{-1} = 1_W$, thus by Proposition 3.9 we have $\beta = \text{Int}([\lambda, \mu, t]) \circ \rho_d$ for some $(\lambda, \mu, t) \in T_0(F)$. Let $t = \text{Diag}(t_1, t_2, t_3)$. In an algebraic closure of $F$, choose $\xi$ such that $\xi^3 = \det t$ and $\eta$ such that $\eta^3 = \lambda^{-1} \mu t_1 t_2$. Then $\beta F = F(\xi, \eta)$. Let also

$$u = \text{Diag}(t_3, \xi^t t_2^{-1}, \xi) \in \text{Diag}_3(\tilde{F})$$

Consider $[\eta, \mu^{-1} \xi, u] \in T(\tilde{F})$. By Proposition 6.6 we have

$$\rho_d [\eta, \mu^{-1} \xi, u] = [(\mu^{-1} \xi)^{-1} \det u, \eta, \pi^{-1} u \bar{x}]$$

On the other hand,

$$[\eta, \mu^{-1} \xi, u] \cdot [\lambda, \mu, t] = [\lambda \eta, \xi, ut]$$

and computation shows that

$$\xi (\mu^{-1} \xi \eta)^{-1} \det u = \lambda \eta \quad \text{and} \quad \xi (\pi^{-1} u \bar{x}) = ut.$$  

Therefore, we have

$$[\eta, \mu^{-1} \xi, u] \cdot [\lambda, \mu, t] \cdot \rho_d [\eta, \mu^{-1} \xi, u]^{-1} = 1 \quad \text{in} \quad \text{PGO}^+_8(\tilde{F}),$$

**References:**

hence, letting \( \tau = \text{Int} ([\eta, \mu^{-1} \xi, u]) \),
\[
\tau \circ (\text{Int} ([\lambda, \mu, t]) \circ \rho_\delta) \circ \tau^{-1} = \rho_\delta.
\]
Since \( \beta = \text{Int} ([\lambda, \mu, t]) \circ \rho_\delta \), this shows that \( \beta \) and \( \rho_\delta \) are conjugate. \( \Box \)

We next consider the case where \( \overline{\beta} = \overline{\rho_\delta} \).

**Proposition 7.4.** Let \( \beta \in \text{Aut}(\PGO_4^+ \times T)(F) \) be such that \( \overline{\beta} = \overline{\rho_\delta} \) and \( \beta^3 = 1 \). If \( F \) does not contain any \( \omega \neq 1 \) such that \( \omega^3 = 1 \) (in particular if \( F \) has characteristic 3), then \( \beta \) is conjugate in \( \text{Aut}(\PGO_4^+)(F) \) to \( \rho_\delta \). If \( F \) contains an element \( \omega \neq 1 \) such that \( \omega^3 = 1 \), then \( \beta \) is conjugate to \( \rho_\sigma \) or to \( \rho_\phi \).

**Proof.** As in Proposition 7.3, we may assume that \( \beta = \text{Int} ([\lambda, \mu, t]) \circ \rho_\sigma \) for some \( (\lambda, \mu, t) \in T(F) \). Since \( \beta^3 = 1 \), we must have
\[
\text{Int} ([\lambda, \mu, t]) \circ \rho_\sigma [\lambda, \mu, t] \cdot \rho_\sigma^2 [\lambda, \mu, t] = 1,
\]
By Proposition 6.5, we have
\[
[\lambda, \mu, t] \cdot \rho_\sigma [\lambda, \mu, t] \cdot \rho_\sigma^2 [\lambda, \mu, t] = [\det t, \det t, t^3].
\]
Therefore, letting \( t = \text{Diag}(t_1, t_2, t_3) \), we see that the condition \( \beta^3 = 1 \) implies
\[
t_1^3 = t_2^3 = t_3^3 = t_1 t_2 t_3.
\]
Let \( \omega = t^3 t_1^{-1} \). We then have \( \omega^3 = 1 \) and \( t_3 = \omega^2 t_1 \), hence \( t = t_1 w \) where \( w = \text{Diag}(1, \omega, \omega^2) \). For \( u = \text{Diag}(\lambda, \mu, \mu) \), computations using Proposition 6.5 show that
\[
[\mu, t_1, u] \cdot [\lambda, \mu, t_1 w] \cdot \rho_\sigma [\mu, t_1, u]^{-1} = [t_1, t_1, t_1 w] = [1, 1, w].
\]
Therefore, letting \( \sigma = \text{Int} ([\mu, t_1, u]) \) we have
\[
(7.5) \quad \sigma \circ \text{Int} ([\lambda, \mu, t_1 w]) \circ \rho_\sigma \circ \sigma^{-1} = \text{Int} ([1, 1, w]) \circ \rho_\sigma.
\]
If \( \omega = 1 \), then \( w = 1 \), and (7.5) shows that \( \beta \) is conjugate to \( \rho_\sigma \). If \( \omega \neq 1 \), observe that \( (1, 1, w) \in T_0(F) \) acts on the quadratic space of Zorn matrices as the automorphism \( s_\omega^{-1} \) of (5.6): we have
\[
[1, 1, w] \circ \xi = s_\omega^{-1} (\xi) \quad \text{for all } \xi \in C.
\]
Therefore, for the Petersson twist \( \nabla = o_s \), we have \( \text{Int} ([1, 1, w]) \circ \rho_\sigma = \rho_\nabla \) by Proposition 4.9(ii), and (7.5) shows that \( \beta \) is conjugate to \( \rho_\nabla \). But we saw in Lemma 5.12 that \( \nabla \) is isomorphic to \( \triangle \), hence by Lemma 4.7 the trialitarian automorphisms \( \rho_\nabla \) and \( \rho_\sigma \) are conjugate. Therefore, \( \beta \) is conjugate to \( \rho_\delta \). \( \Box \)

We get to the main result:

**Theorem 7.6.** Let \( n \) be a 3-Pfister form over a field \( F \), let \( G \) be either \( \PGO_\pm(n) \) or \( \text{Spin}(n) \) and let \( \phi \in \text{Aut}(G)(F) \) be any trialitarian automorphism. There is a finite field extension \( \overline{F} \) of \( F \) splitting \( G \) and such that \( \phi \) is conjugate over \( \overline{F} \) to one of the two standard trialitarian automorphisms of \( \PGO_4^+ \) or \( \text{Spin}_4 \).
Proof. After enlarging $F$ to split $G$, the claim follows from Propositions 7.2, 7.3, 7.4 and Theorem 3.6.

Thus there are two types of trialitarian automorphisms of $\text{PGO}^+(n)$ or $\text{Spin}(n)$. We call those conjugate over a field extension of $F$ to $\rho_\diamond$ of octonion type and the others of Okubo type. Using the correspondence between trialitarian automorphisms and symmetric compositions in Theorem 4.8, we readily derive the classification of 8-dimensional symmetric composition algebras, first established by Petersson [Pet69, Satz 2.7] over fields of characteristic different from 2 and 3, and by Elduque-Pérez [EP96] over arbitrary fields:

**Theorem 7.7.**

(i) Let $F$ be an algebraically closed field. The para-Zorn algebra $(C, \diamond, n)$ and the split Okubo algebra $(C, \triangle, n)$ are non-isomorphic symmetric composition algebras.

(ii) For every 8-dimensional symmetric composition algebra $(S, \star, n)$ over an arbitrary field $F$ there is a finite field extension $\tilde{F}$ of $F$ such that $(S, \star, n) \otimes F \tilde{F}$ is either isomorphic to the para-Zorn algebra or to the split Okubo algebra over $\tilde{F}$.

It follows from Theorem 7.7 that symmetric composition algebras of dimension 8 over an arbitrary base field can be divided into two types, according to their isomorphism class over an algebraic closure. Those that after scalar extension are isomorphic to the split Okubo algebra are called Okubo algebras. As we shall see in Theorem 8.2, those that after scalar extension are isomorphic to the para-Zorn algebra are the para-octonion algebras defined after Lemma 5.4. Thus:

**Corollary 7.8.** Symmetric composition algebras of dimension 8 are either para-octonion algebras or Okubo algebras.

8. AUTOMORPHISMS OF SYMMETRIC COMPOSITIONS

Let $(S, \star, n)$ be a symmetric composition algebra of dimension 8 with associated trialitarian automorphism $\rho_\star$. We let $\text{Aut}(\star)$ or $\text{Aut}(S, \star, n)$ denote the $F$-algebraic group of automorphisms of $\star$, whose group of $F$-rational points $\text{Aut}(\star)$ consists of the automorphisms $f: \star \to \star$. This group is related to $\rho_\star$ as follows:

**Proposition 8.1.** The canonical map $\text{GO}^+(n) \to \text{PGO}^+(n)$ induces an isomorphism from $\text{Aut}(\star)$ to the subgroup $\text{PGO}^+(n)^{\rho_\star}$ of $\text{PGO}^+(n)$ fixed under the trialitarian automorphism $\rho_\star$.

**Proof.** See [CKT12, Theorem 6.6].

In view of Theorem 7.6 we have two types of subgroups fixed under trialitarian automorphisms, those which are automorphism groups of para-octonion algebras and those which are automorphism groups of Okubo algebras.

We next determine the type of the algebraic group $\text{Aut}(\star)$, and show that this group determines the composition $\star$ up to isomorphism or anti-isomorphism.
Type I: Para-octonion algebras. Let $(C, \cdot, n)$ be an octonion algebra over an arbitrary field $F$, and let $\circ$ be the corresponding para-octonion multiplication on $(C, n)$ (see Lemma 5.4).

Theorem 8.2. (i) The octonion algebra $(C, \cdot, n)$ and the para-octonion algebra $(C, \circ, n)$ have the same groups of automorphisms.

(ii) Forms of para-octonion algebras are para-octonion algebras.

(iii) The group of automorphisms of any para-octonion algebra is an algebraic group of type $G_2$.

Proof. The equality $\text{Aut}(\circ) = \text{Aut}(\cdot)$ is proved in [KMRT98, (34.4)]. Claim (i) and (ii) now follow from the fact that algebraic groups of type $G_2$ are the automorphism groups of octonion algebras (see i.a. [SV00, §1.7]). □

We collect more related known results in the next proposition. Sketches of proofs are given for completeness.

Proposition 8.3. Let $(C, \cdot, n)$ and $(C', \cdot', n')$ be octonion algebras, and let $\circ$ resp. $\circ'$ be the corresponding para-octonion multiplications. The following properties are equivalent:

(i) $(C, \cdot, n)$ and $(C', \cdot', n')$ are isomorphic.

(ii) $(C, \circ, n)$ and $(C', \circ', n')$ are isomorphic.

(iii) The norms $n$ and $n'$ are isometric.

(iv) The algebraic groups $\text{Aut}(\cdot)$ and $\text{Aut}(\cdot')$ are isomorphic.

(v) The algebraic groups $\text{Aut}(\circ)$ and $\text{Aut}(\circ')$ are isomorphic.

(vi) The algebraic groups $\text{PGO}^+(n)$ and $\text{PGO}^+(n')$ are isomorphic.

Proof. The equivalence of (i) and (ii) is proved in [KMRT98, (34.4)] and the equivalence of (i) and (iii) is for example in [KMRT98, (33.19)] or [SV00, §4.3]. Claims (i), (ii), and (iii) imply (iv), (v), and (vi) are clear, and the equivalence of (iv) and (v) is Theorem 8.2. If $\text{Aut}(\cdot) \xrightarrow{\sim} \text{Aut}(\cdot')$, then $\text{Aut}(\cdot)(F) \xrightarrow{\sim} \text{Aut}(\cdot')(F)$ and (i) follows by [vdBS59, (2.3)]. The implication (iv) $\implies$ (i) can also be obtained by a cohomological argument. Let $G = \text{Aut}(\cdot)$ and let $G' = \text{Aut}(\cdot')$. Forms of $(C, \cdot, n)$ are classified by $H^1(F, G)$ and forms of $G$ by $H^1(F, \text{Aut}(G))$, for étale or fppf-cohomology. The algebra $(C', \cdot', n')$, being a form of $(C, \cdot, n)$, gives a cohomology class $[\xi] \in H^1(F, G)$ and $G'$ is the twisted group $^G\xi$. If $G' \xrightarrow{\sim} G$, then the image of $\xi$ in $H^1(F, \text{Aut}(G))$ under the map $H^1(F, G) \to H^1(F, \text{Aut}(G))$ induced by inner conjugation $\iota: G \to \text{Aut}(G)$ is trivial. However the map $\iota$ is an isomorphism for groups of type $G_2$. Thus $[\xi]$ is trivial and $(C, \cdot, n) \xrightarrow{\sim} (C', \cdot', n')$. The implication (vi) $\implies$ (iii) can also be obtained by a similar cohomological argument. Namely, let $[\xi] \in H^1(F, \text{Aut}(\cdot))$ correspond to $(C', \cdot', n')$ and assume that its image in $H^1(F, \text{PGO}^+(n))$ is trivial. First we recall that $\text{Aut}(\cdot)$ is a subgroup of $\text{GO}^+(n)$ and that similar Pfister forms are isomorphic. Thus it suffices to consider the norm forms $n$.
and \( n' \) up to similarity and we are reduced to show that the image of \([\xi]\) in \(H^1(F, \text{GO}^+(n))\) is trivial. We next remark that the map \(H^1(F, \text{GO}^+(n)) \to H^1(F, \text{PGO}^+(n))\) induced by the projection has trivial kernel. This follows from the fact that in the exact sequence
\[
H^1(F, \mathbb{G}_m) \to H^1(F, \text{GO}^+(n)) \to H^1(F, \text{PGO}^+(n))
\]
induced by
\[
1 \to \mathbb{G}_m \to \text{GO}^+(n) \to \text{PGO}^+(n) \to 1,
\]
the set \(H^1(F, \mathbb{G}_m)\) is trivial by Hilbert 90. Let \( H = \text{PGO}^+(n) \). It remains to verify that \( H^1(F, H) \to H^1(F, \text{Aut}(H)) \) has trivial kernel. Since \( \text{Aut}(H)(F) = (H \rtimes \mathbb{S}_3)(F) \to \mathbb{S}_3(F) = \mathbb{S}_3 \) is surjective this follows from the cohomology sequence
\[
(H \rtimes \mathbb{S}_3)(F) \to \mathbb{S}_3(F) \to H^1(F, H) \to H^1(F, \text{Aut}(H))
\]
induced by the exact sequence
\[
1 \to H \to H \rtimes \mathbb{S}_3 \to \mathbb{S}_3 \to 1.
\]
Thus, the composition
\[
H^1(F, \text{Aut}(\cdot)) \to H^1(F, \text{GO}^+(n)) \to H^1(F, H) \to H^1(F, \text{Aut}(H))
\]
has trivial kernel and we are done. \(\square\)

**Corollary 8.4.** Forms of para-Zorn algebras are para-octonion algebras. In particular there is up to isomorphism a unique para-octonion algebra with given 3-Pfister form \( n \).

**Proof.** In view of Proposition 8.3 the classification of para-octonion algebras is equivalent to the classification of octonion algebras. Thus the claim follows from the known fact that forms of octonion algebras are octonion algebras. \(\square\)

For Okubo algebras we treat separately fields of characteristic not 3 and fields of characteristic 3.

**Type II: Okubo algebras in characteristic different from 3.** We distinguish two subtypes IIa and IIb, depending on whether the base field contains a primitive cube root of unity or not. Suppose first \( F \) contains a primitive cube root of unity \( \omega \). Let \( A \) be a central simple \( F \)-algebra of degree 3. For the reduced characteristic polynomial of \( a \in A \), we use the notation
\[
X^3 - \text{Trd}(a)X^2 + \text{Srd}(a)X - \text{Nrd}(a)1,
\]
so Trd is the reduced trace map on \( A \), Srd is the reduced quadratic trace map, and Nrd is the reduced norm. Let \( A^0 \subset A \) be the kernel of Trd.

**Proposition 8.5.** Assume that \( F \) contains a primitive cubic root of unity.
(i) The multiplication $\star$ on $A^0$ given by

$$x \star y = \frac{yx - \omega xy}{1 - \omega} - \frac{1}{3} \text{Trd}(xy)$$

(8.6)

together with the quadratic form

$$n(x) = -\frac{1}{7} \text{Srd}(x).$$

(8.7)

define an Okubo algebra on the quadratic space $(A^0, n)$, which is hyperbolic.

(ii) The symmetric composition $(A^0, \star, n)$ and the algebra $A$ have the same groups of automorphisms.

Proof. See for instance [KMRT98, (34.19), (34.25)] and [KMRT98, (34.35)]. □

If $F$ does not contain a primitive cube root of unity $\omega$, we denote $K = F(\omega)$ the separable quadratic extension generated by $\omega$. Let $B$ be a central simple $K$-algebra of degree 3 with a unitary involution $\tau$ leaving $F$ fixed and let $\text{Sym}(B, \tau)^0$ be the $F$-vector space of $\tau$-symmetric elements of reduced trace zero.

**Proposition 8.8.** Assume that $F$ does not contain a primitive cube root of unity $\omega$.

(i) The quadratic space $(\text{Sym}(B, \tau)^0, n)$ is a 3-fold Pfister quadratic space that becomes hyperbolic over $K$, and the restriction of the product $\star$ and of the norm $n$ of $B$ to $\text{Sym}(B, \tau)^0$ define a symmetric composition on this space.

(ii) The symmetric composition $((\text{Sym}(B, \tau)^0, \star, n)$ and the algebra with involution $(B, \tau)$ have the same groups of automorphisms.

Proof. See [KMRT98, (34.35)]. □

**Corollary 8.9.**

(i) If $F$ contains a primitive cube root of unity $\omega$, Okubo algebras over $F$ are in functorial bijective correspondence with central simple algebras over $F$ of degree 3.

(ii) Let $K = F(\omega)$ if $F$ does not contain $\omega$. Okubo algebras over $F$ are in functorial bijective correspondence with central simple algebras of degree 3 over $K$, with unitary $K/F$-involution.

(iii) The group of automorphisms of an Okubo algebra over a field $F$ of characteristic not 3 is an algebraic group of inner type $^1A_2$ if $F$ contains a primitive cube root of unity $\omega$ and of outer type $^2A_2$ if $F$ does not contain $\omega$. In the latter case it becomes a group of inner type over $F(\omega)$.

Proof. It follows from Proposition 8.5 and Proposition 8.8 that the classification of Okubo algebras over $F$ is equivalent to the classification of central simple algebras of degree 3 over $F$, resp. of central simple algebras of degree 3 over $F(\omega)$. In particular they have isomorphic groups of automorphisms. □
Proposition 8.10. Two Okubo algebras \((S,\star,n)\) and \((S',\star',n')\) over a field \(F\) of characteristic not 3 are isomorphic or anti-isomorphic if and only if their groups of automorphisms \(\text{Aut}(\star)\) and \(\text{Aut}(\star')\) are isomorphic.

Proof. In view of Corollary 8.9, the claim follows from the corresponding fact for central simple algebras, which is certainly known. However, since the only reference we could find was at the level of Lie algebras ([Jac79, Chap. X, §4]), we give here a cohomological proof in the spirit of the proof of Proposition 8.3. Assume that \(F\) contains a cube root of unity. Let \(A\) and \(A'\) be central simple \(F\)-algebras of degree 3 and let \(G = \text{Aut}(A)\), \(G' = \text{Aut}(A')\). First assume that \(A\) is split, so that \(G = \text{PGL}_3\) and \(\text{Aut}(G) = G \rtimes \mathfrak{S}_2\). Let \([\xi] \in H^1(F,G)\) be a cocycle defining \((S',\star',n')\) or equivalently \(A'\). If \(G' \to G\), the image of \([\xi]\) in \(H^1(F,\text{Aut}(G))\) is trivial. From the exact sequence

\[
G(F) \to \text{Aut}(G)(F) \xrightarrow{\lambda} \mathfrak{S}_2 \xrightarrow{\nu} H^1(F,G) \to H^1(F,\text{Aut}(G))
\]

we conclude that \([\xi]\) lies in the image of \(\nu\). But \(\lambda\) is surjective because we are in the split case, hence \([\xi] = 1\) and \(A' \to A\). If \(A\) is not split, \(\lambda\) is not surjective and the kernel of \(H^1(F,G) \to H^1(F,\text{Aut}(G))\) consists of two elements. Thus we have exactly two choices for \([\xi]\), resp. for the algebra \(A'\). On the other hand we have two candidates, the algebra \(A\) and the opposite algebra \(A^{\text{op}}\). Obviously \(A\) and \(A^{\text{op}}\) have the same group of automorphisms and they are not isomorphic: if \(A \to A^{\text{op}}\), the class of \(A\) in the Brauer group of \(F\) would have order smaller than or equal to 2. But since \(A\) is of degree 3 and is not split, its Brauer class has order 3. A similar argument can be given if \(F\) does not contain a cube root of unity. \(\square\)

Type III: Okubo algebras in characteristic 3. The algebraic group of automorphisms of the split Okubo algebra in characteristic 3 is more intricate than in characteristic different from 3. In particular the group is not smooth. Its set of \(F\)-points was computed in [Eld99, Theorem 7], see also [Tit59, §10] and [GL83, (9.1)] for the computation of fixed \(F\)-points under triality. The next sections are devoted to the computation of this algebraic group of automorphisms.

Remark 8.11. We conclude this section by verifying that the graph automorphism \(\rho\) and the trialitarian automorphism \(\rho_\circ\) defined through the para-Zorn algebra \((C,\circ,n)\) are conjugate in \(\text{Aut}(\text{PGO}_4^+)(F)\). We know already that the induced actions on the Weyl group are conjugate (see Remark 6.12). Thus, by Proposition 7.4 \(\rho\) is conjugate to \(\rho_\circ\) or to \(\rho_\Delta\), the automorphism associated to the split Okubo algebra. Since the subgroup fixed by \(\rho\) is of type \(G_2\), while the fixed subgroup of \(\rho_\Delta\) is a simple group of type \(A_2\) if the characteristic is different from 3 (Proposition 8.10), or not smooth if the characteristic is 3 (Section 10), we obtain that \(\rho\) is conjugate to \(\rho_\circ\).
9. Idempotents of Composition Algebras in Characteristic 3

For simplicity we assume throughout this section that the base field $F$ has characteristic 3, even if some of the results hold for arbitrary fields. Let $(H, \cdot, n)$ be a Hurwitz algebra and let $(H, \circ, n)$ be the associated para-Hurwitz symmetric composition (see Lemma 5.4). The identity element of $(H, \cdot)$ also plays a special role for the associated para-Hurwitz algebra. It is an idempotent (i.e., $1 \circ 1 = 1$) and satisfies $1 \circ x = x \circ 1 = -x$ for $x \in H$ such that $b_n(1, x) = 0$.

**Definition 9.1.** An idempotent $e$ of a symmetric composition $(S, \star, n)$ is called a para-unit if $e \star x = x \star e = -x$ for $x \in S$ such that $b_n(e, x) = 0$.

We recall that a symmetric composition is para-Hurwitz if and only if it admits a para-unit (see [KMRT98, (34.8)]).

Let now $(S, \star, n)$ be an Okubo algebra.

**Definition 9.2.** We say that an idempotent $e$ of $(S, \star, n)$ is quaternionic if $e$ is the para-unit of a para-quaternion subalgebra of $(S, \star, n)$. We say that an idempotent $e$ of $(S, \star, n)$ is quadratic if $e$ is not quaternionic, and $e$ is the para-unit of a para-quadratic subalgebra of $(S, \star, n)$.

We give examples of such elements in the split Okubo algebra $(C, \triangle, n)$, as described in (5.5) using Zorn matrices:

**Lemma 9.3.**

(i) The Zorn matrix $e = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ is a quadratic idempotent.

(ii) The Zorn matrix $\hat{e} = \begin{pmatrix} 1 & -(1,1,1) \\ (1,1,1) & 1 \end{pmatrix}$ is a quaternionic idempotent.

**Proof.** (i) The element $e$ is the para-unit of the para-quadratic subalgebra

$$Q = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & \beta \end{pmatrix} \mid \alpha, \beta \in F \right\}.$$

Moreover $e$ cannot be the para-unit of any para-quaternion subalgebra, as this would imply that this subalgebra (with nondegenerate norm!) would be contained in the centralizer of $e$. But the centralizer $\text{Cent}_{(C, \Delta, n)}(e) = \{ x \in C \mid x \Delta e = e \Delta x \}$ of $e$ is the set of Zorn matrices

$$Z = \left\{ \begin{pmatrix} \alpha \\ (y,y,y) \end{pmatrix} \begin{pmatrix} \alpha & x \\ x, x \end{pmatrix} \mid \alpha,\beta,x,y \in F \right\},$$

and the restriction of the norm to this centralizer is degenerate.

(ii) In the same vein, $\hat{e}$ is an idempotent and the set of Zorn matrices

$$H = \left\{ \begin{pmatrix} \alpha \\ (x,y,z) \end{pmatrix} \begin{pmatrix} \alpha & -(x,y,z) \\ (x,y,z) \end{pmatrix} \mid \alpha,\beta,x,y,z \in F \right\}$$

is a para-quaternion subalgebra with para-unit $\hat{e}$. \qed

Documenta Mathematica 18 (2013) 413–468
We next give another construction of an Okubo algebra with a quaternionic idempotent:

**Example 9.4.** Let \( Q = \text{Mat}_2(F) \) be the split quaternion algebra (multiplication denoted by juxtaposition) with conjugation:

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.
\]

The split octonion algebra can be constructed through the Cayley-Dickson doubling process as \( C = Q \oplus Qv \), with multiplication, conjugation and norm given by

\[
(a + bv) \cdot (c + dv) = (ac + \overline{d}b) + (da + b\overline{c})v,
\]

(9.5)

\[
a + bv = \overline{a} - bv,
\]

\[
n(a + bv) = \det(a) - \det(b).
\]

The element \( w = (\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}) \) satisfies \((w - 1)^2 = 0, w\overline{w} = 1, \overline{w} = w^2 = -1 - w\), and the map

\[
\vartheta: a + bv \mapsto a + (wb)v, \quad a, b \in Q
\]

(9.6)

is an order 3 automorphism of \((C, \cdot)\). Let \( \star = \cdot \vartheta \) be the associated Petersson twist, i.e.,

\[
x \star y = \vartheta(\overline{x}) \cdot \vartheta^2(\overline{y}) \quad \text{for } x, y \in C.
\]

(9.7)

Obviously, \( e = 1 \) is an idempotent of the symmetric composition \((C, \star, n)\), and \((Q, \star, n)\) is a para-quaternion subalgebra, since the restriction of \( \vartheta \) to \( Q \) is the identity, with para-unit \( e \). Thus \( e \) is also quaternionic.

**Lemma 9.8.** The symmetric composition algebra \((C, \star, n)\) is an Okubo algebra.

**Proof.** In view of Corollary 7.8 it suffices to show that \((C, \star, n)\) is not a para-octonion algebra. The decomposition \( C = Q \oplus Qv \) is a \( \mathbb{Z}_2 \)-grading of both \((C, \cdot)\) and \((C, \star)\). Hence the commutative center

\[
K(C, \star) = \{ x \in C \mid x \star y = y \star x, \ \forall y \in C \}
\]

is graded: \( K(C, \star) = (K(C, \star) \cap Q) \oplus (K(C, \star) \cap Qv) \). If \((C, \star, n)\) were a para-octonion algebra, its commutative center would be one-dimensional and spanned by a nonzero idempotent. Hence we would have \( K(C, \star) = K(C, \star) \cap Q \), and this is contained in the commutative center of the para-quaternion algebra \((Q, \star)\), which is \( Fe \). But \( e \star v = -w^2v \) while \( v \star e = -uv \). \( \Box \)

**Proposition 9.9.** If an Okubo algebra \((S, \star, n_S)\) admits a quaternionic idempotent \( f \), there is an isomorphism \( \varphi: (S, \star, n_S) \rightarrow (C, \star, n) \) such that \( \varphi(f) = e \). In particular \((C, \star, n)\) is isomorphic to the split Okubo algebra, and the unique Okubo algebra that contains a quaternionic idempotent is, up to isomorphism, the split Okubo algebra.
Proof. For the new multiplication
\[ x \cdot y = (f \ast x) \ast (y \ast f), \]
\((S, \cdot, n_S)\) is a Cayley algebra with unity \(f\), the map
\[ \vartheta_S(x) = (f \ast (f \ast x)) = n_S(f, x)f - x \ast f \]
is an automorphism of \((S, \cdot)\) and of \((S, \ast)\), of order 3, such that \(\ast = \cdot \vartheta_S\) is the twist with respect to \(\vartheta_S\) (see [KMRT98, (34.9)]). Let \(P\) be a para-quaternion subalgebra of \((S, \ast)\) with para-unit \(f\). Then the restriction of \(\vartheta_S\) to \(P\) is the identity. Let \(z \in P^\perp\) with \(n_S(z) \neq 0\), so \(P^\perp = P \cdot z\). Then \(S = P \oplus P \cdot z\) and \(\vartheta_S(z) = u \cdot z\) for some \(u \in P\). But then \(u^3 = 1\), so \((u - 1)^3 = 0 \neq u - 1\).

We conclude that \((P, \cdot)\) is the split quaternion algebra. Then \(z\) can be taken with \(n_S(z) = -1\). Moreover, there is an isomorphism \((P, \cdot) \to \text{Mat}_2(F)\) that takes \(u\) to the element \(w\) in Example 9.4, and this isomorphism extends to a unique isomorphism \(\varphi: (S, \cdot) \to (C, \cdot)\) such that \(\varphi(z) = w\). Obviously \(\varphi(f) = e\) and \(\varphi \vartheta_S = \vartheta \varphi\). This last condition implies that \(\varphi\) is also an isomorphism \((S, \ast, n_S) \to (C, \ast, n)\). Moreover, since the split Okubo algebra contains a quaternionic idempotent (see Lemma 9.3), there is a unique Okubo algebra up to isomorphism containing quaternionic idempotents.

Our aim now is to prove that the quaternionic idempotent in the split Okubo algebra is unique. The Okubo algebra \((C, \ast, n)\) in Example 9.4 is isomorphic to the split Okubo algebra, since it contains a quaternionic idempotent. Thus we may use it as a model of the split Okubo algebra. We keep the notation used in Example 9.4. The subalgebra of \((C, \ast)\) of elements fixed under the order 3 automorphism \(\vartheta\) is \(Q \oplus IV\), where \(I = \{a \in Q \mid wa = a\} = \{a \in Q \mid (w - 1) a = 0\} = (w - 1)Q\), because \((w - 1)^2 = 0\). (Note that it is clear that \((w - 1)Q\) is contained in the subspace of elements of \(Q\) annihilated by \(w - 1\), the equality holds since both subspaces are proper right ideals of \(Q\), and hence both of them have dimension 2.) Therefore, the centralizer of \(e\) in \((C, \ast, n)\) is
\[
\text{Cent}_{(C, \ast, n)}(e) = \{x \in C \mid e \ast x = x \ast e\} = \{x \in C \mid \vartheta^2(x) = \vartheta(x)\} = \{x \in C \mid \vartheta(x) = x\} = Q \oplus IV,
\]
and it is a six-dimensional subalgebra of both \((C, \cdot)\) and \((C, \ast)\). Note also that 
\[
IV = \{x \in \text{Cent}_{(C, \ast, n)}(e) \mid b_n(x, \text{Cent}_{(C, \ast, n)}(e)) = 0\}
\]
is precisely the radical of \(\text{Cent}_{(C, \ast, n)}(e)\) relative to the polar form of the norm, and \((IV) \ast (IV) = TIV = Q(w - 1)^2Q = 0\), so \(IV\) is a nilpotent ideal of \((\text{Cent}_{(C, \ast, n)}(e), \ast)\). Since \((Q, \ast)\) is simple, \(IV\) is the largest nilpotent ideal of \((\text{Cent}_{(C, \ast, n)}(e), \ast)\).

Let \(Z = \text{Cent}_{(C, \ast, n)}(e)\) and let \(K(Z, \ast) = \{x \in Z \mid x \ast y = y \ast x, \forall y \in Z\}\).

Lemma 9.11. \(K(Z, \ast) = Fe\).

(i) \(K(Z, \ast) = Fe\).

(ii) Any subalgebra of \((Z, \ast)\) of dimension \(\geq 4\) contains \(e\).
Proof. Clearly $e$ belongs to $K(Z, *)$. Also $(Z, *)$ is $\mathbb{Z}_2$-graded, so
\[ K(Z, *) = (K(Z, *) \cap Q) \oplus (K(Z, *) \cap I_v). \]

Since $(Q, *)$ is a para-quaternion algebra, its commutative center is spanned by $e$, which is its para-unit. On the other hand, for any $a \in Q$ and $b \in I$, $a \star (bv) = -\overline{a} \cdot (bv) = -(\overline{a}v)\overline{b}$, while $(bv) \star a = -(bv) \cdot \overline{a} = -(ba)v$. Hence, if $bv$ is in $K(Z, *)$, then $ba = b\overline{a}$ for any $a \in Q$, so $b(a - \overline{a}) = 0$ for any $a \in Q$, and $b = 0$ since we may find elements $a \in Q$ with $n(a - \overline{a}) \neq 0$.

For the second part, let $Z_0 = \{x \in Z \mid b_n(x, x) = 0\}$, so $Z = F\alpha \oplus Z_0$. If $T$ is a subalgebra of $(Z, *)$ and $e \notin T$, then the projection $\pi: T \to Z_0$ is one-to-one, and hence for any $x \in \pi(T)$ there is a unique $\alpha \in F$ such that $\alpha e + x \in T$. But $(\alpha e + x)^2 = (\alpha e - x)^2 = \alpha^2 e - 2\alpha x + x^2 = \alpha(\alpha e - x) - n(x)e$, so $n(x)e \in T$ for any $x \in \pi(T)$. Since we are assuming $e \notin T$, $\pi(T)$ consists of isotropic vectors and hence $\dim T = \dim \pi(T) \leq 3$, because $\dim Z_0 = 5$ and the rank of the restriction of $n$ to $Z_0$ is $3$. \qed

**Corollary 9.12.** If $f$ is a quaternionic idempotent of the split Okubo algebra $(C, *, n)$, then $f \in Z$.

**Proof.** We know by Proposition 9.9 and by formulas (9.10) that $Z = Cent(C, *, n)(e)$ and $Cent(C, *, n)(f)$ are six-dimensional subalgebras. Hence $Cent(C, (*, n))(f) \cap Z$ has dimension at least 4, so it contains $e$ by Lemma 9.11. Hence $e$ lies in $Cent(C, (*, n))(f)$, $e \star f = f \star e$, and this is equivalent to $f \in Z$. \qed

**Theorem 9.13.** The split Okubo algebra contains a unique quaternionic idempotent.

**Proof.** By Corollary 9.12 it suffices to study the nonzero idempotents in the subalgebra $Z$ of the split Okubo algebra $(C, *, n)$. For $a \in Q$ and $\beta \in I = (w - 1)Q$, we have
\[
(a + bv)^2 = \overline{(a - bv)} = b_n(0, 1)(a - bv) - n(a - bv)1 = b_n(a, 1)(a - bv) - n(a)1,
\]
and this is an idempotent if and only if
\[
\begin{align*}
(a + bv)^2 &= n(a)1, \\
b &= -b_n(a, 1)b.
\end{align*}
\]
Hence $a = b_n(a, 1)(b_n(a, 1)1 - a) - n(a)1$, or
\[
(1 + b_n(a, 1))a = (b_n(a, 1)^2 - n(a))1.
\]
Now, if $b_n(a, 1) \neq -1$ we conclude from (9.14) that $a \in F1$ and $b = 0$, so $a = 1 = e$.

On the other hand, if $b_n(a, 1) = -1$, then we conclude from (9.15) that $n(a) = 1$ and hence $(a - 1)^2 = 0$. Then we assume from now on that $(a - 1)^2 = 0$.

If $b = 0$, then either $a = 1 = e$, or $a$ is conjugate in $Q$ to $w = (\frac{1}{0} \frac{1}{1})$. In this last case, for $x, y \in Q$, $x + yv$ is in the centralizer of $a$ if and only if so are $x$ and $yv$, but $x \star a = a \star x$ if and only if $\overline{a} = \overline{a}$, if and only if $ax = xa$, if and only if $x \in F1 + Fa$. And $(yw) \cdot a = a \cdot (yw)$ if and only if $-((wy)v) = -(\overline{w}((w^2)y)v)$, if and only if $wya = w^2y\overline{a}$. Since $\overline{a} = a^2 = a^{-1}$, this is equivalent to $ya^2 = wy$v.
But this equation does not hold for all $y \in Q$, and hence the dimension of $\text{Cent}_{(C,\ast,n)}(a)$ is not 6, and $a$ is not a quaternionic idempotent.

If $b \neq 0$, we compute again $\text{Cent}_{(C,\ast,n)}(a + bv)$. For $x, y \in Q$,

$$(x + yv) \ast (a + bv) = (\pi - (wy)v) \cdot (\pi - bv)$$

$$= ((\pi \pi + byw) - (b\pi + wy)v),$$

$$(a + bv) \ast (x + yv) = (\pi - bv) \cdot (\pi - (w^2y)v)$$

$$= (\pi \pi + w^2yb) - (bx + w^2y\pi)v.$$

Hence, $x + yv$ is in $\text{Cent}_{(C,\ast,n)}(a + bv)$ if and only if

$$\pi \pi + byw = \pi \pi + ywb \quad \text{and} \quad b\pi + wyv = bx + w^2y\pi.$$  

But $wb = b$, because $a + bv \in Z$, so $\pi w = w^2b = b$. Thus, this is equivalent to

$$(9.16) \quad \pi \pi + by = \pi \pi + yb \quad \text{and} \quad b\pi + wy = bx + w^2y\pi.$$  

If $a = 1$, this gives $by = yb$, so $\pi y \in F1$. But $n(b) = 0$, so $\pi y = 0$, or $y \in bQ$.

Note that $I$ is a minimal right ideal of $Q$, so $bQ = I$ and $y \in I$. Hence the centralizer of $a + bv$ is contained in $Q + Iv$. But then $wy = y$ and we obtain $b\pi = bx$, or $b(x - \pi) = 0$. We conclude that $Q$ is not contained in the centralizer of $a + bv$, so $\dim \text{Cent}_{(C,\ast,n)}(a + bv)$ is not 6 and $a + bv$ is not a quaternionic idempotent.

Finally, if $a \neq 1$ and we take $y \in bQ = I$, we have as before $\pi y = 0 = yb$, so $\pi \pi = \pi \pi$, and hence $x \in F1 + Fa$. If $a + bv$ were a quaternionic element, the dimension of $\text{Cent}_{(C,\ast,n)}(a + bv)$ would be 6, and hence the dimension of $\text{Cent}_{(Z,\ast,n)}(a + bv)$ would be at least 4. Therefore we would have $\text{Cent}_{(Z,\ast)}(a + bv) = (F1 + Fa) + Iv$. But for $y \in I$, $yv \in \text{Cent}_{(Z,\ast)}((a + bv)$ if and only if $ya = y\pi$ because of $(9.16)$, if and only if $y(a - 1) = 0$. We conclude that $I(a - 1) = 0$, or $(w - 1)Q(a - 1) = 0$, and this is impossible since $Q$ is simple (and hence prime).

For any Okubo algebra $(S,\ast,n)$, the cube form $g(x) = b_n(x, x \ast x)$ plays a key role (see [EP96, §5], [KMT98, (36.11)]).

**Lemma 9.17** (see [Eld97]). Let $(S,\ast,n)$ be an Okubo algebra. Then:

(i) The cubic form $g$ is semilinear, i.e. $g(\alpha x + y) = \alpha^3 g(x) + g(y)$ for any $
\alpha \in F$ and $x, y \in S$.

(ii) For any $x \in S$, we have $g(\alpha^2) = g(x)^2 + n(x)^3$.

(iii) The set $F^3 + g(S)$ is a subfield of $F$ (a purely inseparable field extension of $F^3$ of exponent 1).

(iv) The quadratic form $n$ is isotropic (and hence its Witt index is 4).

**Theorem 9.18.** Let $(C,\triangle,n)$ be the split Okubo algebra represented by Zorn matrices (see §5), over an algebraically closed field $F$. Consider the subset

$$O = \{x \in C \mid n(x) = 0, g(x) = 1\}.$$

Then:
(i) The set \( O \) is an irreducible closed subset of \( C \) in the Zariski topology.

(ii) For any \( x \in O \), \( e = x + x \triangle x \) is an idempotent of \((C, \triangle, n)\) which

is either quadratic or quaternionic.

(iii) The subset \( O_0 = \{ x \in O \mid x + x \triangle x \) is a quadratic idempotent\} coincides

with the orbit of \( e_1 \) under the automorphism group of \((C, \triangle, n)\).

(iv) For any \( x \in O_0 \) and any \( y \in C \) such that \( x \triangle y = 0 \), \( b_n(x, y) = 0 \) and \( g(y) = 1 \), there is an

automorphism \( \varphi \) of \((C, \triangle, n)\) such that \( \varphi(e_1) = x \) and \( \varphi(u_1) = y \).

(v) The subset \( O_0 \) is a nonempty open subset of \( O \), and the subset \( O_1 = \{ x \in O \mid x + x \triangle x \) is a quaternionic idempotent\} is a closed subset of \( O \).

Proof. (i) Let \( e_1 \) and \( f_1 \) be as in (5.3). Note first that \( e_1 \) belongs to \( O \), as

\( e_1 \triangle e_1 = f_1 \) and \( g(e_1) = b_n(e_1, f_1) = 1 \). Since the cubic form \( g \) is semilinear

(Lemma 9.17), the subset \( \{ x \in C \mid g(x) = 1 \} \) coincides with the set \( e_1 + \{ x \in C \mid g(x) = 0 \} \),

which is isomorphic to an affine space of dimension 7. It follows

that \( O \) is a quadric in this affine space, and one easily checks that this quadric

is irreducible.

(ii) For any \( x \in O \), \( x \triangle (x \triangle x) = n(x)x = 0 \), while

\[ (x \triangle x) \triangle (x \triangle x) + ((x \triangle x) \triangle x) \triangle x = b_n(x, x \triangle x)x \]

(see 4.3), so \( (x \triangle x) \triangle (x \triangle x) = x \). Hence \( e = x + x \triangle x \) is an idempotent, the

para-unit of the para-quadratic subalgebra spanned by \( x \) and \( x \triangle x \). Thus \( e \) is
either quadratic or quaternionic.

(iii) Note that \( e_1 \in O_0 \) as \( e = e_1 + e_1 \triangle e_1 = e_1 + f_1 \) is a quadratic idempotent

(Lemma 9.3). Recall that the Hurwitz product \( \cdot \) is recovered as

\[ x \circ y = (e \triangle x) \triangle (y \triangle e). \]

For any \( z \in O_0 \), let \( f = z + z \triangle z \), and consider the new multiplication on \( C \):

\[ x \circ y = (f \triangle x) \triangle (y \triangle f). \]

Then \((C, o, n)\) is a Cayley algebra with identity element \( f \) and the map \( \vartheta(x) =

\[ f \triangle (f \triangle x) = b_n(f, x)f - x \triangle f \] is an automorphism of \((C, o, n)\) of order 3.

Besides, \( x \triangle y = \vartheta(\widehat{x}) \circ \vartheta^2(\widehat{y}) \), where \( \widehat{x} = b_n(f, x) - x \) for any \( x \), so the

Okubo algebra \((C, \triangle, n)\) is the twist \((C, o, n)\) of \((C, o, n)\) by \( \vartheta \) (see [KMRT98,

(34.9)]). The automorphism \( \vartheta \) fixes the elements \( z \) and \( z \triangle z \) of \((C, o, n)\), and

hence the subalgebra \( K = \text{span} \{ z, z \triangle z \} \) of \((C, o, n)\). Moreover, \( \vartheta(x) = x \) if

and only if \( b_n(f, x)f - x \triangle f = x \), and this implies \( f \triangle x = b_n(f, x) - f \triangle

(f \triangle f) = b_n(f, x)f - x = x \triangle f \). Conversely, if \( f \triangle x = x \triangle f \), then \( \vartheta(x) = f \triangle (f \triangle x) = f \triangle (x \triangle f) = n(f)x = x \), so the subalgebra of \((C, o, n)\)
of the elements fixed by \( \vartheta \) coincides with the centralizer of \( f \) in \((C, \triangle, n)\).

Besides, \( \vartheta^3 = \text{Id} \), so \( (\vartheta - \text{Id})^3 = 0 \). If \( (\vartheta - \text{Id})^2 \) were 0, then there would exist
an element \( x \) orthogonal to \( K \) such that \( \vartheta(x) = x \) and \( n(x) \neq 0 \), but then the
subalgebra \( K \oplus K \circ x \) would be a para-quaternion subalgebra with para-unit \( f \),
a contradiction with \( f \) being quadratic. Hence the restriction of \( \vartheta \) to \( K^\perp \) has
minimal polynomial \((X - 1)^3\) and the arguments in [EP96, proof of Proposition 1.1] show that there exists an isomorphism \(\varphi: (C, \cdot, n) \to (C, \circ, n)\) such that \(\varphi(\lambda_1) = z, \varphi(\lambda_1) = z \triangle z\) and such that \(\varphi_{\pi} = \varphi\) (recall that \((C, \triangle, n)\) is the twist \((C, \circ, n)_s\)). Therefore \(\varphi\) is an automorphism of \((C, \triangle, n)\) and \(\varphi(\lambda_1) = z\).

(iv) Note that \(0 = y \triangle (x \triangle y) = n(y)x, \) so \(n(y) = 0\). Also,
\[
b_n(x \triangle x, y) = -b_n(x, x \triangle y) = 0, \quad b_n(x, y \triangle y) = b_n(x \triangle y, y) = 0
\]
and
\[
b_n(x \triangle x, y \triangle y) = b_n(y, y \triangle (x \triangle x)) = b_n(y, -b_n(x, y)x + x \triangle (x \triangle y)) = 0.
\]
Therefore the subalgebras span \(\{x, x \triangle x\}\) and span \(\{y, y \triangle y\}\) are orthogonal and the result follows now from [Eld09, Theorem 3.12].

(v) As \(\text{Cent}_{(C, \triangle, n)}(e_1 + e_1 \triangle e_1) = \text{span} \{e_1, f_1, u_1 + u_2 + u_3, v_1 + v_2 + v_3\}\), we have that \(\text{Cent}_{(C, \triangle, n)}(x + x \triangle x)\) has dimension 4 for any \(x \in O_0\). On the other hand, for any \(x \in O_1, x + x \triangle x\) is the unique quaternionic idempotent, whose centralizer has dimension 6. Since for any \(x, \text{Cent}_{(C, \triangle, n)}(x) = \ker(l_x - r_x), \)
where \(l_x\) and \(r_x\) denote the left and right multiplication by \(x\) in \((C, \triangle, n)\), we obtain:
\[
O_0 = \{x \in O \mid \text{rank}(l_{x+\Delta x} - r_{x+\Delta x}) = 4\}
\]
\[
= \{x \in O \mid \text{rank}(l_{x+\Delta x} - r_{x+\Delta x}) > 2\},
\]
and this is open in \(O\).

**Corollary 9.19.** Let \((C, \triangle, n)\) be the Okubo algebra with the multiplication table (5.11) over an algebraically closed field \(F\), and let \(\lambda \in F\) be nonzero. The subset
\[
O^\lambda = \{x \in C \mid n(x) = 0, g(x) = \lambda\}
\]
is an irreducible closed subset of \(C\), and its subset \(O_0^\lambda = \{x \in O^\lambda \mid \lambda^{1/3}x \in O_0\}\) is a nonempty open subset of \(O^\lambda\).

Given an Okubo algebra \((S, \star, n)\) over a field \(F\) and a field extension \(K/F\), denote by \(O(K)\) the subset \(\{x \in S \otimes_F K \mid n(x) = 0, g(x) = 1\}\) (the extensions of \(n\) and \(g\) to \(S \otimes_F K\) are denoted by the same letters). The same applies to \(O^\lambda(K)\). For any field \(F\), let \(\overline{F}\) denote an algebraic closure of \(F\).

**Corollary 9.20.** Let \((S, \star, n)\) be an Okubo algebra over an infinite field \(F\) and let \(\lambda \in F\) be nonzero. If the set \(O^\lambda(F)\) is not empty, then it is a closed irreducible subset of \(S\) and its subset \(O_0^\lambda(F) := O^\lambda(F) \cap O_0^\lambda(\overline{F})\) is a nonempty open subset.

10. **Automorphisms of the split Okubo algebra**

The rational points of the groups of automorphisms of Okubo algebras over fields of characteristic 3 have been computed in [Eld99], by relating the Okubo algebras with some noncommutative Jordan algebras. In this section the existence of a unique quaternionic idempotent in the split Okubo algebra will be used to compute its group of automorphisms inside the group of automorphisms of the split Cayley algebra. We systematically assume that the base field \(F\) has
characteristic 3. As in Example 9.4, consider the split Cayley algebra $(C, \cdot, n)$, with $C = Q \oplus Q e$, and the order 3 automorphism $\vartheta$ in (9.6) such that its restriction to $Q$ is the identity and $\vartheta(v) = wv$ with $1 \neq w \in Q$ such that $w^3 = 1$. The Petersson twist $\ast = \ast_\vartheta$ is the split Okubo algebra multiplication.

**Proposition 10.1.** $\text{Aut}(C, \ast, n)(F) = \{ \psi \in \text{Aut}(C, \cdot, n)(F) \mid \psi \vartheta = \vartheta \psi \}$.

**Proof.** Obviously, any automorphism of $(C, \cdot, n)$ commuting with $\vartheta$ is an automorphism of $(C, \ast, n)$. Conversely, if $\psi$ is an automorphism of $(C, \ast, n)$, then $\psi(e) = e$, because $e$ is the unique quaternionic idempotent, and since $\vartheta(x) = e \ast (e \ast x)$ for any $x \in C$, we conclude that $\psi$ commutes with $\vartheta$. \hfill \Box

It is no longer true that the quaternionic idempotent $e$ of $(C, \ast, n)$ is fixed by all automorphisms of the extension $(C \otimes_F R, \ast, n)$, for any unital commutative associative algebra $R$. However, the automorphisms that fix $e \otimes 1_R$ coincide with the automorphisms of $(C \otimes_F R, \cdot, n)$ that commute with $\vartheta$ (more precisely with the automorphism $\vartheta \otimes 1_R$). Denote by $H$ the centralizer of the automorphism $\vartheta$ in the group scheme of automorphisms $\text{Aut}(C, \cdot, n)$. Alternatively, $H$ is the stabilizer of $e$ (or of $Fe$). By (9.10) any $\varphi \in H(R)$ leaves $Iv \otimes_F R$ invariant, since $Iv$ is the radical of the restriction of the norm to the subalgebra of fixed elements by $\vartheta$. Therefore there is a morphism

$$(10.2) \quad \Phi : H \rightarrow \text{GL}(I),$$

that takes any automorphism $\varphi \in \text{Aut}((C \otimes F R, \ast, n))$ commuting with $\vartheta \otimes 1_R$ to the linear automorphism $\Phi(\varphi) = f$ of $I \otimes F R$ defined by $\varphi(xv) = f(x)v$, for any $x \in I \otimes F R$. Given any element $a \in \text{SL}_2(R)$ there is a unique automorphism $\psi_a$ of $(C \otimes F R, \cdot, n)$ such that $\psi_a(xa^{-1}) = axa^{-1}$ and $\psi_a(xv) = (xa^{-1})v$ for $x \in Q \otimes F R = \text{Mat}_2(R)$. This automorphism commutes with $\vartheta$. Thus we get a closed embedding of $\text{SL}_2$ into $H$. Denote by $S$ its image. Moreover, $\text{GL}(I)$ will be identified with $\text{GL}_2$, with $a \in \text{GL}_2(R) = (Q \otimes F R, \ast)$ being identified with the map $xv \mapsto (xa^{-1})v$. With these identifications we get the following result:

**Theorem 10.3.**

(i) $\Phi(H) = \text{SL}_2$.

(ii) $H$ is the semidirect product of $\ker \Phi$ and $S$.

**Proof.** As in the proof of Theorem 9.13, we may assume $w = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. Hence $I = (w - 1)Q$ is the right ideal of $2 \times 2$ matrices with trivial second row. Let $J$ be the right ideal of $2 \times 2$ matrices with trivial first row, so $Q = I \oplus J$. For simplicity, given a unital commutative associative algebra $R$, we write $Q_R = Q \otimes F R$ and similarly $I_R, J_R$. Take $\varphi \in H(R)$ and let $a \in \text{GL}_2(R)$ be its image under $\Phi$, so $\varphi(xv) = (xa^{-1})v$ for any $x \in I$. For $x \in Q_R$, $\varphi(x) = \varphi_0(x) + \sigma(x)v$ for $R$-linear maps $\varphi_0 : Q_R \rightarrow Q_R$ and $\sigma : Q_R \rightarrow I_R$. Then, for $x \in Q_R$ and $y \in I_R$,

$$\varphi(x \cdot (yv)) = \begin{cases} \varphi((yx)v) = (yxa^{-1})v, \\
\varphi(x) \cdot \varphi(yv) = (\varphi_0(x) + \sigma(x)v) \cdot ((ya^{-1})v) = (ya^{-1})\varphi_0(x)v,
\end{cases}$$

with $[\varphi] = a \otimes 1_R$.
as $(iv)^2 = 0$. Thus $y(xa^{-1} - a^{-1} \varphi_0(x)) = 0$ for any $x \in Q_R$, $y \in I_R$, so
\[ \varphi_0(x) = axa^{-1}. \]
Now, for $x \in J_R$, $\varphi(xv) = \mu(x)v + \nu(x) + \delta(x)v$ for some $R$-linear maps $\mu: J_R \to J_R$, $\nu: J_R \to Q_R$ and $\delta: J_R \to I_R$. Hence, with $\vartheta$ as in (9.6), we have
\[ \varphi \vartheta(xv) = \varphi((wx)v) = \varphi(xv) + \varphi((w-1)x)v \]
\[ = \mu(x)v + \nu(x) + (\delta(x) + (w-1)xax^{-1})v, \]
\[ \vartheta \varphi(xv) = \vartheta(\mu(x)v + \nu(x) + \delta(x)v) \]
\[ = (w\mu(x))v + \nu(x) + \delta(x)v \]
\[ = \mu(x)v + \nu(x) + ((w-1)\mu(x) + \delta(x))v. \]
We get $(w-1)xax^{-1} = (w-1)\mu(x)$, so $\mu(x) - xa^{-1}$ lies in $J_R$ and it is annihilated by $(w-1)$, and hence lies in $I_R$. Thus $\mu(x) = xa^{-1}$ for any $x \in J_R$.
But $\varphi$ is an isometry of the norm too, so for any $x \in J_R$ and $y \in I_R$,
\[ b_n(x,y) = -b_n(xy,yv) = -b_n(\varphi(xy),\varphi(yv)) \]
\[ = -b_n((xa^{-1})v, (ya^{-1})v) = b_n(xa^{-1}, ya^{-1}) = n(a^{-1})b_n(x,y), \]
and we conclude that $\det(a) = n(a) = 1$. This proves (i). Finally, the assignment $a \mapsto \psi_a$ gives a section of the epimorphism $\Phi: H \to \text{SL}_2$. \hfill \Box

We next compute the group $\ker \Phi$.

**Lemma 10.4.** Let $(C, \cdot, n)$ be the Zorn algebra as in §5. Let $R$ be a unital commutative associative algebra over $F$ and let $W$ be a free $R$-submodule of $C \otimes_F R$ of rank $3$ with $n(W) = 0 = b_n(W,1)$ and $1 \in b_n(W, W^{-2})$. Let $\{w_1, w_2, w_3\}$ be a basis of $W$ with $b_n(w_1, w_2, w_3) = 1$. Let $\{e_1, f_1, u_1, u_2, u_3, v_1, v_2, v_3\}$ be the canonical basis of $C$. Then there is a unique automorphism $\varphi \in \text{Aut}(C \otimes_F R, \cdot, n)$ such that $\varphi(e_i) = w_i$ for $i = 1, 2, 3$.

**Proof.** The uniqueness follows from the fact that $u_1, u_2, u_3$ generate $(C, \cdot)$. Consider the trilinear form given by $\Lambda(x, y, z) = b_n(x, y \cdot z)$. For any $x \in W$, $n(x) = 0 = b_n(x, 1)$, so $x^2 = 0$, and hence $x \cdot y = -y \cdot x$ for any $x, y \in W$.
Moreover, for all $x, y \in W$,
\[ \Lambda(x, x, y) = b_n(x, x \cdot y) = n(x)b_n(1, y) = 0, \]
\[ \Lambda(x, y, y) = b_n(x, y^2) = 0, \]
so $\Lambda$ is alternating on $W$. In particular, we have $\Lambda(x, y, z) = \Lambda(y, z, x) = \Lambda(z, x, y)$ for any $x, y, z \in W$.
Let $W$ be the linear span (over $R$) of $w_2 \cdot w_3$, $w_3 \cdot w_1$ and $w_1 \cdot w_2$. Taking indices modulo 3 we get $n(w_1 \cdot w_{i+1}) = 0$ and
\[ b_n(w_1 \cdot w_{i+1}, w_{i+1} \cdot w_{i+2}) = -b_n(w_{i+1} \cdot w_i, w_{i+1} \cdot w_{i+2}) \]
\[ = -n(w_{i+1})b_n(w_i, w_{i+2}) = 0, \]
so $W$ is isotropic. Also, $b_n(w_1 \cdot w_{i+1}, 1) = b_n(w_i, w_{i+1}) = 0$. Moreover
\[ b_n(w_i, w_{i+1} \cdot w_{i+2}) = \Lambda(w_i, w_{i+1}, w_{i+2}) = 1, \]
while
\[ b_n(w_i, w_i \cdot w_{i+1}) = n(w_i)b_n(1, w_{i+1}) = 0 = b_n(w_i, w_{i+2} \cdot w_i). \]

Therefore, \( W \) and \( \hat{W} \) are paired by the polar form of the norm.

Now, since we have \( x \cdot (y \cdot z) + y \cdot (x \cdot z) = (x \cdot y + y \cdot x) \cdot z, \) we get
\[ w_1 \cdot (w_2 \cdot w_3) = w_2 \cdot (w_1 \cdot w_3) = w_3 \cdot (w_1 \cdot w_3), \]
and also
\[ (w_1 \cdot w_2) \cdot w_3 = (w_2 \cdot w_3) \cdot w_1 = (w_3 \cdot w_1) \cdot w_2. \]

But
\[ w_1 \cdot (w_2 \cdot w_3) + (w_2 \cdot w_3) \cdot w_1 = -b_n(w_1, w_2 \cdot w_3)1 = -1. \]

As \( n(w_1 \cdot (w_2 \cdot w_3)) = 0 \) and \( b_n(w_1 \cdot (w_2 \cdot w_3), 1) = -b_n(w_2 \cdot w_3, w_1) = -1, \) it turns out that \( \hat{e}_1 = -w_1 \cdot (w_2 \cdot w_3) \) is an idempotent, and so is \( \hat{f}_1 = 1 - \hat{e}_1 = -(w_2 \cdot w_3) \cdot w_1. \) Then
\[ w_1 \cdot \hat{e}_1 = w_1 \cdot (w_1 \cdot (w_{i+1} \cdot w_i + 1)) = w_1^2 \cdot (w_{i+1} \cdot w_i + 1) = 0, \]
and we get \( \hat{f}_1 \cdot w_i = 0 \) in a similar vein. Also \( \hat{e}_1 \cdot (w_i \cdot w_{i+1}) = 0 = (w_i \cdot w_{i+1}) \cdot \hat{f}_1, \)
and it follows easily that \( \{\hat{e}_1, \hat{f}_1, w_1, w_2, w_3, w_2 \cdot w_3, w_3 \cdot w_1, w_1 \cdot w_2\} \) is a basis of \( C \otimes F R \) with the same multiplication table as for the canonical basis over \( F. \)

Consider now an automorphism \( \varphi \in \text{Aut}(C \otimes F R, \cdot, n) \) that commutes with \( \vartheta \) and which belongs to \( \text{ker } \Phi, \) that is, \( \varphi \) fixes the elements in \( I_{RV}. \) Then for any \( x \in Q \otimes R, \) \( x \) is fixed by \( \vartheta, \) and hence so is \( \varphi(x). \) Thus, as in the proof of Theorem 10.3 (with \( a = 1 \)), we obtain \( \varphi(x) = x + \sigma(x)v \) for any \( x \in Q, \) for an \( R \)-linear map \( \sigma: Q \otimes R \to I_{RV}. \)

We may take a canonical basis \( \{e_1, f_1, u_1, u_2, u_3, v_1, v_2, v_3\} \) of \( C \) such that \( Q = \text{span } \{e_1, f_1, u_1, v_1\}, \) \( w = 1 - u_1 \) and \( v = u_3 - v_3. \) Then \( I = (w - 1)Q = \text{span } \{e_1, u_1\}, \) \( I_v = \text{span } \{u_3, v_3\}. \) Also, \( \vartheta(u_2) = \vartheta(v_2) = (wv_1)v = ((1 - u_1)v_1)v = (v_1 - e_1) \cdot (u_3 - v_3) = u_2 + u_3. \) In particular, \( \varphi(u_3) = u_3, \) since we are assuming that \( \varphi \) leaves the elements in \( I_{RV}, \) and \( \varphi(u_1) = u_1 + \alpha u_3 + \beta v_2 \) for some \( \alpha, \beta \in R, \) since \( \varphi(u_1) - u_1 \in I_{RV}. \) Besides, for any \( x \in I_{RV}, \)
\[ b_n(\varphi(u_2), x) = b_n(\varphi(u_2), \varphi(x)) = b_n(u_2, x), \] so \( \varphi(u_2) - u_2 \in (I_{RV})^2 = Q \otimes I_{RV}. \) As \( b_n(\varphi(u_2), 1) = b_n(u_2, 1) = 0, \) we conclude that \( \varphi(u_2) = u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2 \) for some \( \gamma, \delta, \mu, \nu, \rho \in R. \) Hence
\[ \varphi(u_1) = u_1 + \alpha u_3 + \beta v_2, \]
(10.5)
\[ \varphi(u_2) = u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2, \]
\[ \varphi(u_3) = u_3, \]
and this determines \( \varphi \) completely because the elements \( u_1, u_2, u_3 \) generate \( C. \) Conversely, Lemma 10.4 shows that for any \( \alpha, \beta, \gamma, \delta, \mu, \nu, \rho \in R, \) there is a unique automorphism \( \varphi \) satisfying (10.5) if and only if the elements \( u_1 + \alpha u_3 + \beta v_2, u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2 \) and \( u_3 \) span an isotropic space and
\[ b_n(u_1 + \alpha u_2 + \beta v_2, (u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2) \cdot u_3) = 1. \]
But
\[ n(u_1 + \alpha u_3 + \beta v_2) = 0 = n(u_3), \]
\[ n(u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2) = -\gamma^2 + \rho + \delta \mu, \]
while
\[ b_n(u_1 + \alpha u_3 + \beta u_2, u_3) = 0 = b_n(u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2, u_3) \]
\[ b_n(u_1 + \alpha u_3 + \beta v_2, u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2) = \mu + \beta, \]
and
\[ b_n(u_1 + \alpha u_3 + \beta u_2, (u_2 + \gamma(e_1 - f_1) + \delta u_1 + \mu v_1 + \nu u_3 + \rho v_2) \cdot u_3) = b_n(u_1 + \alpha u_3 + \beta v_2, v_1 + \gamma u_3 - \delta v_2) = 1. \]
Hence the only restrictions on the scalars \(\alpha, \ldots, \rho\) so that equation (10.5) determines an automorphism are
\[ \beta = -\mu, \quad \rho = \gamma^2 - \delta \mu. \]
If these conditions are satisfied, then \(\varphi \vartheta(u_1) = \vartheta \varphi(u_1)\) and \(\varphi \vartheta(u_3) = \vartheta \varphi(u_3)\) since \(u_1, u_3, \varphi(u_1), \varphi(u_3)\) are fixed by \(\vartheta\). Also, \(\varphi \vartheta(u_2) = \varphi(u_2 + u_3) = \varphi(u_2) + u_3\), while \(\vartheta(\varphi(u_2) - u_2) = \varphi(u_2) - u_2\), so \(\vartheta \varphi(u_2) = \varphi(u_2) - u_2 + \vartheta(u_2) = \varphi(u_2) + u_3 = \varphi \vartheta(u_2)\). Hence \(\varphi \vartheta = \vartheta \varphi\).
Since \(u_1, u_2, u_3\) generate the Cayley algebra \((C, \cdot)\), we can easily compute the images of any basic element. It turns out that the coordinate matrix in the basis \(\{u_2, v_3, e_1, f_1, u_1, v_1, u_3, v_2\}\) of an arbitrary element in \(\ker \Phi(R)\) is of the form
\[
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\gamma & -\mu & 1 & 0 & 0 & 0 & 0 & 0 \\
-\gamma & \mu & 0 & 1 & 0 & 0 & 0 & 0 \\
\delta & -\gamma & 0 & 0 & 1 & 0 & 0 & 0 \\
\mu & -\alpha & 0 & 0 & 0 & 1 & 0 & 0 \\
\nu & \mu^2 - \alpha \gamma & -\mu & \mu & \alpha & \gamma & 1 & 0 \\
\gamma^2 - \delta \mu & \alpha \delta - \mu \gamma - \nu & -\mu & \mu & \alpha & \gamma & 1 & 0 \\
-\gamma & -\gamma & -\mu & -\delta & 0 & 1 & 0 & 1
\end{pmatrix}
\]
\[
(10.6)
\]
Proposition 10.7. The algebraic group \(\ker \Phi\) is smooth unipotent of dimension 5. It is represented by the Hopf algebra which, as an algebra, is the polynomial ring in 5 variables \(F[\alpha, \gamma, \delta, \mu, \nu]\), with comultiplication given by \(\alpha, \gamma, \delta, \mu\) being primitive and \(\Delta(\nu) = \nu \otimes 1 + 1 \otimes \nu + \mu \otimes \gamma + \gamma \otimes \mu + \alpha \otimes \delta\).

Proof. Everything follows from the coordinate expression in equation (10.6). \(\Box\)

Corollary 10.8. \(H\) is a smooth group scheme.

Proof. Both \(\ker \Phi\) and \(SL_2\) are smooth group schemes, so \(H\) is smooth ([KMRT98, (22.12)]) \(\Box\)

Proposition 10.9. The group \(\ker \Phi\) is split unipotent.

\textbf{Documenta Mathematica} 18 (2013) 413–468
Proof. Consider the ideal in the ring of regular functions $F[\alpha, \gamma, \delta, \mu, \nu]$ of $\ker \Phi$ generated by $\alpha, \gamma, \delta, \mu$. It is a Hopf ideal because $\alpha, \gamma, \delta, \mu$ are primitive elements. Hence it corresponds to a closed group subscheme, say $Z$, isomorphic to $G_a$ and consisting of all matrices of the form

$$
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
\nu & 0 & 0 & 0 & 0 & 1
\end{pmatrix}
$$

It is straightforward to check that $Z$ is in the center of $\ker \Phi$, hence normal. The quotient map $\ker \Phi \to (\ker \Phi)/Z$ corresponds to the embedding $F[\alpha, \gamma, \delta, \mu, \nu] \hookrightarrow F[\alpha, \gamma, \delta, \mu, \nu]$ of Hopf algebras. Since $\alpha, \gamma, \delta, \mu$ are primitive elements it follows that $(\ker \Phi)/Z \cong G_a \times G_a \times G_a \times G_a$ and the claim follows. □

**Proposition 10.10.** The scheme $H$ is a closed subgroup of the group scheme of automorphisms $\text{Aut}(C, \star, n)$ of the split Okubo algebra and $H = \text{Aut}(C, \star, n)_{\text{red}}$.

**Proof.** The scheme $H$ is the stabilizer in $\text{Aut}(C, \star, n)$ of the quaternionic idempotent $e$. Let $A$ be the Hopf algebra representing $\text{Aut}(C, \star, n)$, and let $I$ be the Hopf ideal such that $A/I = \text{H\text{g}(C, \star, n)}$. Since $H$ is smooth, $I$ is a radical ideal. But $H(F) = \text{Aut}(C \otimes F, \star, n) = \text{Aut}(C, \star, n)(F)$ by Proposition 10.1. By Hilbert’s Nullstellensatz $I$ coincides with the radical of $A$. Hence the radical of $A$ is a Hopf ideal, and $H = \text{Aut}(C, \star, n)_{\text{red}}$. □

**11. The Group Scheme of Automorphisms of the Split Okubo Algebra**

We continue assuming that the characteristic of the ground field $F$ is 3.

Given any Okubo algebra $(S, \star, n)$, the arguments in [Eld97] and [Eld99] show that the vector space $A = F1 \oplus S$, with the multiplication given by

$$1 \cdot x = x = x \cdot 1,$$

$$a \cdot b = \frac{1}{2}(a \star b + b \star a + 2b_n(a, b)1) = -(a \star b + b \star a) + b_n(a, b)1,$$

for $x \in A$ and $a, b \in S$, is a 9-dimensional commutative and associative algebra.

We give a proof for completeness. We start with

**Lemma 11.2.** Every Okubo algebra $(S, \star, n)$ is Lie admissible, i.e., $S$ becomes a Lie algebra with bracket $[x, y]^\star = x \star y - y \star x$.

**Proof.** This can be proved using the multiplication table in (5.11), but we can proceed in a different way, which has its own independent interest. The result
is clear for the unique (split) Okubo algebra over the complex numbers, since it can be defined as the space of zero trace $3 \times 3$ matrices with the product
\[
x \star y = \frac{yx - \omega xy}{1 - \omega} - \frac{1}{3} \text{trace}(xy) 1
\]
where $\omega$ is a primitive cube root of unity and $xy$ denotes the usual matrix multiplication (see (8.6)). In this case $[x,y]^* = \frac{\omega^2}{1-\omega}(xy - yx)$, so the Jacobi identity holds, and the Okubo algebra is Lie admissible. It has a basis \{e1, f1, v1, u2, v2, v3, v4\} with the same multiplication table as in (5.11). Consider the subalgebra $E$ over $\mathbb{Z}$ spanned by the elements of this basis. Then $(E, \star)$ is a Lie algebra over $\mathbb{Z}$ with the bracket $[x,y]^\star = x \star y - y \star x$, and so is $(E \otimes_\mathbb{Z} F, \star)$ over $F$. But $(E \otimes_\mathbb{Z} F, \star)$ is the split Okubo algebra over $F$. Hence the split Okubo algebra is Lie-admissible, and the result follows since any Okubo algebra splits after a scalar extension. \hfill \Box

**Proposition 11.3.** The algebra $(A, \cdot)$, with multiplication (11.1), is a commutative and associative algebra. Moreover, if $(S, \ast, n)$ is split, then $(A, \cdot)$ is isomorphic to the algebra of truncated polynomials $F[X, Y]/(X^3, Y^3)$.

**Proof.** By its own definition $(A, \cdot)$ is commutative. To prove the associativity, it is enough to check that any associator $(a, b, c) = (a \cdot b) \cdot c - a \cdot (b \cdot c)$ is trivial. This is clear if one of the elements is 1, and hence we may assume that $a, b, c$ are in $S$. Then we get, using Lemma 11.2,
\[
0 = \left( [a, b]^*, c \right)^* + \left( [b, c]^*, a \right)^* + \left[ [c, a]^*, b \right]^* \\
= (a \cdot (c \cdot (a \cdot b) - b \cdot (a \cdot c - c \cdot a)) + (c \cdot b - b \cdot c) - a \cdot (b \cdot c - c \cdot b) + (b \cdot a - a \cdot b) \cdot c - c \cdot (b \cdot a - a \cdot b) \\
= - (b \cdot (c \cdot a) + b_n(a, b)c + (b \cdot a) \cdot c - b_n(b, c)a + c \cdot (a \cdot b) \\
- b_n(b, c)a - a \cdot (c \cdot b) + b_n(a, b)c + (c \cdot b - b \cdot c) \cdot a \\
- a \cdot (b \cdot (c \cdot b - c \cdot a) + (b \cdot a - a \cdot b) \cdot c - c \cdot (b \cdot a - a \cdot b) \\
= (c \cdot b + b \cdot c) \cdot a + a \cdot (c \cdot b + b \cdot c) + b_n(b, c)a \\
- (b \cdot a + a \cdot b) \cdot c - c \cdot (b \cdot a + a \cdot b) - b_n(a, b)c \\
= a \cdot (b \cdot c) - (a \cdot b) \cdot c = -(a, b, c),
\]
where we have used that $b_n(a, b \cdot c) = b_n(a \cdot b, c)$ and $b_n(a, c \cdot b) = b_n(b \cdot a, c)$. Therefore $(A, \cdot)$ is associative. Take now a canonical basis of the split Okubo algebra $(C, \Delta, n)$ as in (5.11). The elements
\[
x = e_1 - 1 \quad \text{and} \quad y = u_1 - 1
\]
satisfy $x^3 = 0 = y^3$, and the algebra $(A, \cdot)$ is isomorphic to the truncated polynomial algebra $F[X, Y]/(X^3, Y^3)$, with $x$ and $y$ corresponding to the classes of $X$ and $Y$ modulo $(X^3, Y^3)$. \hfill \Box

**Remark 11.5.** For any $a \in S$, the third power $a^3$ in $A$ is
\[
a^3 = (a \cdot a) \cdot a = (a \cdot a - n(a)1) \cdot a \\
= (a \cdot a) \cdot a + b_n(a \cdot a, a)1 - n(a)a = g(a)1,
\]
where $g(x) = b_n(x, x \cdot x)$ is the cubic form considered in Lemma 9.17.
Consider now the split Okubo algebra \((C, \triangle, n)\) and the associated commutative and associative algebra \((A, \cdot)\), \(A = F1 \oplus C\), as above. With the notation used in the previous proof, the ideal \(N\) generated by the elements \(x\) and \(y\) in \((A, \cdot)\) is the radical of \((A, \cdot)\) and \(N^4 = F(x^2 \cdot y^2)\). A straightforward computation gives
\[
(11.6) \quad x^2 \cdot y^2 = 1 + (e_1 + f_1 + u_1 + v_1 + u_2 + v_2 + u_3 + v_3) = 1 + e,
\]
where \(e\) is the quaternionic idempotent of \((C, \triangle, n)\) (Lemma 9.3).

Any automorphism \(\varphi\) of \((C, \triangle, n)\) extends to a unique automorphism of \((A, \cdot)\) by means of \(\varphi(1) = 1\). This is also valid if we extend scalars to a unital commutative associative algebra over \(F\). As usual, given a unital commutative associative algebra \(R\over F\), \(N_R\) will denote \(N \otimes_F R\). Recall that the algebraic group \(H\) is the stabilizer in \(\text{Aut}(C, \triangle, n)\) of the quaternionic idempotent \(e\). (Initially, \(H\) was defined in terms of the model \((C, \ast, n)\) in Example 9.4 of the split Okubo algebra, but this should cause no confusion.)

**Lemma 11.7.** Let \((C, \triangle, n)\) be the split Okubo algebra. Given any unital commutative associative algebra \(R\) over \(F\), an element \(\varphi\) in \(\text{Aut}(C, \triangle, n)(R)\) lies in \(H(R)\) if and only if, when extended to an automorphism of \(A_R, \cdot\), it satisfies \(\varphi((N_R)^4) = (N_R)^4\).

**Proof.** If an automorphism \(\varphi\) of \((C_R, \triangle, n)\) fixes \(e\), then its extension to \((A_R, \cdot)\) fixes \(1 + e\) and hence \(\varphi\) preserves \((N_R)^4\). Conversely, if \(\varphi\) preserves \((N_R)^4\), then there is an element \(\alpha \in R\) such that \(\varphi(1 + e) = \alpha(1 + e)\). But \(\varphi(1) = 1\) and \(\varphi(e) \in C_R\). Hence \(\alpha = 1\) and \(\varphi\) fixes \(e\). \(\square\)

The elements \(e_1\) and \(u_1\) generate the algebra \((C, \triangle)\), and the assignment \(\deg(e_1) = (1, 0), \deg(u_1) = (\overline{1}, \overline{1})\), endows \((C, \triangle)\) with a grading by \(Z_3 \times Z_3\). This gives a morphism of group schemes
\[
\mu_3 \times \mu_3 \to \text{Aut}(C, \triangle, n),
\]
such that for any \(\alpha, \beta \in \mu_3(R)\times \mu_3(R)\), i.e., \(\alpha^3 = \beta^3 = 1\), the image of \((\alpha, \beta)\) is the automorphism \(\psi_{\alpha, \beta}\) of \((C \otimes_F R, \triangle)\) with the property that \(\psi_{\alpha, \beta}(e_1) = \alpha e_1\) and \(\psi_{\alpha, \beta}(u_1) = \beta u_1\). The image \(D\) of this morphism is isomorphic to \(\mu_3 \times \mu_3\). Moreover, since \(b_3(e_1, e_1 \triangle e_1) = 1\) and \(b_3(u_1, u_1 \triangle u_1) = 1\), it turns out that \(D\) is the group scheme of diagonal automorphisms relative to the basis of \((C, \triangle, n)\) in Table (5.11).

**Theorem 11.8.** Let \((C, \triangle, n)\) be the split Okubo algebra. For any unital commutative associative algebra \(R\) over \(F\), \(\text{Aut}(C, \triangle, n)(R) = H(R)D(R)\). Moreover \(H(R) \cap D(R) = 1\).

**Proof.** Since the quaternionic idempotent is \(e = e_1 + f_1 + u_1 + v_1 + u_2 + v_2 + u_3 + v_3\) (the sum of the elements in the basis, see Lemma 9.3), an automorphism fixes \(e\) and is diagonal relative to this basis if and only if it is the identity. Hence we have \(H(R) \cap D(R) = 1\).

Let \(\varphi\) be an element in \(\text{Aut}(C, \triangle, n)(R)\). Extend it to an automorphism of \((A_R, \cdot)\). Then, with \(x\) and \(y\) as in (11.4), there are elements \(\mu, \nu \in R\) such that
\( \varphi(x) - \mu 1 \in N_R \) and \( \varphi(y) - \nu 1 \in N_R \). Since \( x^3 = 0 = y^3 \) and \( N_R \) is an ideal, we have \( \mu^2 = \nu^3 = 0 \). Consider the element \((\alpha, \beta) := (\mu + 1, \nu + 1) \in \mu_3(R) \times \mu_3(R)\) and the automorphism \( \psi_{\alpha, \beta} \in D(R) \). Then we have

\[
\varphi^{-1}_{\alpha, \beta}(x) = \varphi \psi_{\alpha, \beta}(x) \\
= \varphi \psi_{\alpha, \beta}(e - 1) \\
= \varphi(\alpha^2 e - 1) = \varphi(\alpha^2 x + (\alpha^2 - 1)1) \\
\equiv (\alpha^2 - 1)1 + \alpha^2 \mu 1 \pmod{N_R} \\
\equiv (\alpha^2 - 1 + \alpha^2(\alpha - 1))1 \equiv 0 \pmod{N_R}, \text{ as } \alpha^3 = 1,
\]

so \( \varphi^{-1}_{\alpha, \beta}(x) \in N_R \). In a similar vein we get \( \varphi^{-1}_{\alpha, \beta}(y) \in N_R \), and this proves \( \varphi^{-1}_{\alpha, \beta}(N_R) = N_R \), and hence \( \varphi^{-1}_{\alpha, \beta}((N_R)^4) = (N_R)^4 \). By Lemma 11.7 we conclude that \( \varphi^{-1}_{\alpha, \beta} \) lies in \( H(R) \), and hence \( \varphi = (\varphi^{-1}_{\alpha, \beta}) \psi_{\alpha, \beta} \in H(R)D(R) \).

**Proposition 11.9.** Neither of the subgroups \( H \) and \( D \) of \( \text{Aut}(C, \triangle, n) \) is normal.

**Proof.** Consider the automorphism \( \varphi \) of the split Cayley algebra \((C, \cdot, n)\) in (5.1) defined on the canonical basis as

\[
\varphi(e_i) = e_i, \quad \varphi(f_i) = f_i \quad \text{and} \quad \varphi(u_i) = -(u_i + u_{i+1}), \quad \varphi(v_i) = v_i + v_{i+1} - v_{i+2},
\]

for \( i = 1, 2, 3 \) (indices modulo 3). It is straightforward to check that \( \varphi \) is indeed an automorphism, and that it commutes with the automorphism \( s_\tau \) that permutes cyclically the \( u_i \)’s and the \( v_i \)’s. Therefore \( \varphi \) is an automorphism of the split Okubo algebra \((C, \triangle, n)\), where \( \triangle = s_\tau \) is the Petersson twist. And \( \varphi \) preserves the quaternionic idempotent, so \( \varphi \) is in \( H(F) \). Its inverse fixes \( e_1 \) and \( f_1 \) and satisfies

\[
\varphi^{-1}(u_i) = u_i - u_{i+1} + u_{i+2}, \quad \varphi^{-1}(v_i) = v_i - v_{i+2}
\]

for \( i = 1, 2, 3 \). For any unital commutative and associative algebra \( R \) over \( F \) containing an element \( 1 \neq \alpha \in \mu_3(R) \), consider the automorphism \( \psi_{\alpha, 1} \in D(R) \). Then the commutator \( [\varphi, \psi_{\alpha, 1}] = \varphi^{-1}\psi_{\alpha, 1}\varphi \psi_{\alpha, 1} \) fixes \( e_1 \) and takes \( u_1 \) to

\[
\varphi^{-1}\psi_{\alpha, 1}(u_1) = \varphi^{-1}\psi_{\alpha, 1}(u_1) \\
= \varphi^{-1}\psi_{\alpha, 1}(-u_1 - u_2) \\
= \varphi^{-1}(-u_1 - \alpha u_2) \\
= -(u_1 - u_2 + u_3) - \alpha(u_2 - u_3 + u_1) \\
= -(1 + \alpha)u_1 + (1 - \alpha)u_2 - (1 - \alpha)u_3.
\]

In particular \( \Phi = [\varphi, \psi_{\alpha, 1}] \) is not in \( D(R) \), as it does not act diagonally in our basis. But it does not belong to \( H(R) \) either because it does not fix the quaternionic idempotent \( e = e_1 + f_1 + u_1 + e_1 + u_2 + v_2 + u_3 + v_3 \). To check this, note that \( \Phi(u_2) = -\Phi(u_1 \triangle e_1) = -(1 + \alpha)u_2 + (1 - \alpha)u_3 - (1 - \alpha)u_1 \) and

\[
\text{Documenta Mathematica 18 (2013) 413–468}
\]
\[ \Phi(u_3) = -\Phi(u_2 \triangle e_1) = -(1 + \alpha)u_3 + (1 - \alpha)u_1 - (1 - \alpha)u_2. \]

In the same vein \( \Phi(e_i) \) belongs to the linear span of \( v_1, v_2, v_3 \). Then

\[ \Phi(e) = \Phi(e_1 + f_1) + \Phi(u_1 + u_2 + u_3) + \Phi(v_1 + v_2 + v_3) = e_1 + f_1 - (1 + \alpha)(u_1 + u_2 + u_3) + \text{a linear combination of } v_1v_2, v_1 \]

\( \neq e. \)

**Remark 11.10.** The subscheme \( H \) embeds in the simple group scheme \( \text{Aut}(C, \cdot, n) \) of type \( G_2 \) (Proposition 10.1). However, there is no such embedding for \( G = \text{Aut}(C, \triangle, n) \). Actually, an embedding \( G \to \text{Aut}(C, \cdot, n) \) would give a monomorphism of Lie algebras

\[ \iota: \text{Lie}(G) = \text{Der}(C, \triangle, n) \to \text{Der}(C, \cdot, n). \]

But \( \text{Der}(C, \triangle, n) \) contains a simple nonclassical ideal \( i \) of dimension 8 [Eld99], while \( g \) is not simple (the characteristic is 3!) but contains a simple ideal \( j \) of dimension 7 such that the quotient \( g/j \) is again simple and isomorphic, as a Lie algebra, to \( j \) (see [AEMN02]). Then \( \iota \) would induce a Lie algebra homomorphism \( i \to g/j \), which must be 0 by dimension count, and this would give that \( i \) embeds in \( j \), a contradiction, again by dimension count.

**12. The classification of Okubo algebras revisited**

The classification of the Okubo algebras in characteristic 3 was obtained in [Eld97, §5], using previous classification results in [EP96, Theorems B and 5.1]. Here this classification will be revisited in light of the results in the preceding sections.

Still the characteristic of \( F \) is assumed to be 3 in this section.

**Proposition 12.1.** The cohomology set \( H^1_{\text{fppf}}(F, H) \) is trivial.

**Proof.** The group \( H \) is the semidirect product of the split unipotent group \( \ker \Phi \) (see Theorem 10.3) and of \( \text{SL}_2 \). Hence we have an exact sequence

\[ H^1_{\text{fppf}}(F, \ker \Phi) \to H^1_{\text{fppf}}(F, H) \to H^1_{\text{fppf}}(F, \text{SL}_2). \]

The left and right terms are trivial, so is the central term.

**Remark 12.2.** Alternatively, one may proceed as follows. Let \( (C, \triangle, n) \) be the split Okubo algebra and let \( e \) be its (unique) quaternionic idempotent. The group scheme \( H \) is the subscheme of \( \text{Aut}(C, \triangle, n) \) consisting of those elements fixing \( e \):

\[ H = \text{Aut}(C, \triangle, n, e). \]

The twisted forms of \( (C, \triangle, n, e) \) are the Okubo algebras with a quaternionic idempotent. But Proposition 9.9 asserts that the only Okubo algebra containing a quaternionic idempotent is the split Okubo algebra. This shows that \( H^1_{\text{fppf}}(F, H) \) is trivial.
Also, $H$ is smooth and hence we have ([Wat79, (18.5) and (17.8)]):

$$H^1_{\text{fppf}}(F, H) = H^1_{\text{ét}}(F, H) = H^1(\Gamma, H(F_{\text{sep}}))$$

$$= H^1(\Gamma, \text{Aut}(C \otimes F, \Delta, n)) = H^1_{\text{ét}}(F, \text{Aut}(C, \Delta, n)),$$

where $F_{\text{sep}}$ denotes the separable closure of $F$ in $\overline{F}$ and $\Gamma$ the Galois group of the extension $F_{\text{sep}}/F$. (Note that over any field extension $K$ of $F$, $H(K)$ exhausts $\text{Aut}(C \otimes K, \Delta, n)$, since $D(K) = 1$.)

Hence we conclude, without making any appeal to the classification in [Eld97], that the only twisted $F_{\text{sep}}/F$-form of $(C, \Delta, n)$ is, up to isomorphism, $(C, \Delta, n)$ itself:

**Corollary 12.3.** The cohomology set $H^1_{\text{ét}}(F, \text{Aut}(C, \Delta, n))$ is trivial. In particular, if $F$ is perfect, there is up to isomorphism a unique Okubo algebra over $F$.

Take now nonzero elements $\alpha, \beta \in F$, and let $(C_{\alpha, \beta}, \Delta, n)$ be the $F$-subalgebra of $(C \otimes_F \overline{F}, \Delta, n)$ generated by the elements $e_1 \otimes \alpha^\frac{1}{3}$ and $u_1 \otimes \beta^\frac{1}{3}$. This is a twisted form of $(C, \Delta, n)$. Denote by $g_{\alpha, \beta}$ the cubic form on $(C_{\alpha, \beta}, \Delta, n)$ given by $g_{\alpha, \beta}(x) = b_{\alpha}(x, x \Delta x)$. The image $g_{\alpha, \beta}(C_{\alpha, \beta})$ is a $F^3$-subspace of $F$ spanned by the elements $\alpha, \alpha^3, \beta, \beta^3, \alpha \beta, \alpha^2 \beta, \alpha^2 \beta^2$. Moreover, under the bijection

$$H^1_{\text{fppf}}(F, \text{Aut}(C, \Delta, n)) \cong \{\text{Isomorphism classes of Okubo algebras}\},$$

the isomorphism class of $(C_{\alpha, \beta}, \Delta, n)$ corresponds to the class of the cocycle

$$\Psi^{\alpha, \beta} \in \text{Aut}(C, \Delta, n)(\overline{F} \otimes_F \overline{F}) = \text{Aut}(C \otimes_F \overline{F}, \overline{F}, \overline{F})$$

determined by

$$\Psi^{\alpha, \beta}(e_1 \otimes 1 \otimes 1) = e_1 \otimes \alpha^{-\frac{1}{3}} \otimes \alpha^{\frac{1}{3}}, \quad \Psi^{\alpha, \beta}(u_1 \otimes 1 \otimes 1) = u_1 \otimes \beta^{-\frac{1}{3}} \otimes \beta^{\frac{1}{3}}.$$ 

Note that $\alpha^{-\frac{1}{3}} \otimes \alpha^{\frac{1}{3}}$ and $\beta^{-\frac{1}{3}} \otimes \beta^{\frac{1}{3}}$ are cube roots of unity, so $\Psi^{\alpha, \beta}$ belongs to the subscheme $D$.

**Remark 12.5.** The scheme $D$ is isomorphic to $\mu_3 \times \mu_3$, so

$$H^1_{\text{fppf}}(F, D) = \{[\Psi^{\alpha, \beta}] \mid \alpha, \beta \in F^\times\},$$

where $[\Psi^{\alpha, \beta}] = [\Psi^{\alpha', \beta'}]$ if and only if $\alpha' \alpha^{-1}, \beta' \beta^{-1} \in F^3$, see [Wat79, 18.2(a)]. In particular, over perfect fields, $H^1_{\text{fppf}}(F, D)$ is trivial.

**Theorem 12.6.** The mapping $H^1_{\text{fppf}}(F, \mu_3 \times \mu_3) \to H^1_{\text{fppf}}(F, \text{Aut}(C, \Delta, n))$, induced by the inclusion $D \hookrightarrow \text{Aut}(C, \Delta, n)$, is surjective.

**Proof.** This is trivial if $F$ is perfect, in particular if $F$ is finite. Hence we will assume that $F$ is infinite. Let $\xi \in Z^1_{\text{fppf}}(F, \text{Aut}(C, \Delta, n))$ be a cocycle and let $(C^S, \Delta, n)$ be the Okubo algebra $C^S = \{x \in C \otimes F \overline{F} \mid \zeta(x \otimes 1) = \theta(x \otimes 1)\}$, where $\theta : C \otimes_F \overline{F} \otimes_F \overline{F} \to C \otimes_F \overline{F} \otimes_F \overline{F}$, $x \otimes \alpha \otimes \beta \mapsto x \otimes \beta \otimes \alpha$. 

Documenta Mathematica 18 (2013) 413–468
Since the norm of an Okubo algebra is isotropic (Lemma 9.17), $C^\xi$ has a basis of isotropic elements and hence there are elements $x \in C^\xi$ with $n(x) = 0$ and $g(x) = \alpha \neq 0$. Then, by Corollary 9.20, we may take

$$x \in O^\partial_0(F) \subset C^\xi \subset C^\xi \otimes_F \mathbb{F} = C \otimes_F \mathbb{F}.$$ 

Then Theorem 9.18 shows that there is an automorphism $\varphi \in \text{Aut}(C \otimes_F \mathbb{F}, \vartriangle, n)$ such that $\varphi(e_1 \otimes 1) = \alpha^{-\frac{1}{2}} x$. Replacing $\zeta$ by an equivalent cocycle we may assume $x = e_1 \otimes \alpha^\frac{1}{2}$. The subspace $\{ z \in C \mid e_1 \vartriangle z = 0, b_\alpha(e_1, z) = 0 \}$ is spanned by $u_1, u_2, u_3$, thus the subspace $\{ y \in C^\xi \mid x \vartriangle y = 0, b_\alpha(x, y) = 0 \}$ has dimension 3 and it is not contained in the kernel of the semilinear map $g$. Take an element $y \in C^\xi$ with $x \vartriangle y = 0$, $b_\alpha(x, y) = 0$ and $g(y) = \beta \neq 0$. Theorem 9.18 shows that there is an automorphism $\psi \in \text{Aut}(C \otimes_F \mathbb{F}, \vartriangle, n)$ such that $\psi(e_1 \otimes 1) = e_1 \otimes 1, \psi(u_1 \otimes 1) = \beta^{-\frac{1}{2}} y$. Replacing $\zeta$ by an equivalent cocycle we may assume $x = e_1 \otimes \alpha^\frac{1}{2}$ and $y = u_1 \otimes \beta^\frac{1}{2}$ belong to $C_3$. Therefore $\zeta(e_1 \otimes \alpha^\frac{1}{2} \vartriangle 1) = e_1 \otimes 1 \otimes \alpha^\frac{1}{2}$, so $\zeta(e_1 \otimes 1 \otimes 1) = e_1 \otimes \alpha^{-\frac{1}{2}} \otimes \alpha^\frac{1}{2}$, and similarly $\zeta(u_1 \otimes 1 \otimes 1) = u_1 \otimes \beta^{-\frac{1}{2}} \otimes \beta^\frac{1}{2}$. Hence we get $\zeta = \psi \zeta_0$ (see (12.4)).

This shows that any Okubo algebra is isomorphic to $(C_{\alpha, \beta}, \vartriangle, n)$ for some nonzero $\alpha, \beta \in F$. Moreover, the set of isomorphism classes of Okubo algebras is a quotient set of $H^1_{\text{fppf}}(F, \mathfrak{d}_3 \times \mathfrak{d}_3) \cong F^\times/(F^\times)^3 \times F^\times/(F^\times)^3$. It remains to consider the isomorphism conditions:

**Theorem 12.7** (see [Eld97]). For $\alpha, \beta, \alpha', \beta' \in F^\times$, the algebras $(C_{\alpha, \beta}, \vartriangle, n)$ and $(C_{\alpha', \beta'}, \vartriangle, n)$ are isomorphic if and only if

$$g_{\alpha, \beta}(C_{\alpha, \beta}) = g_{\alpha', \beta'}(C_{\alpha', \beta'})$$

and if this common $F^3$-subspace has dimension 8 (i.e., $g_{\alpha, \beta}$ and $g_{\alpha', \beta'}$ are bijective), then the following restriction is required too:

$$g_{\alpha, \beta, n}^{-1}(\alpha') \otimes g_{\alpha, \beta, n}^{-1}(\beta') = 0$$

(this is a product of two elements in $(C_{\alpha, \beta}, \vartriangle, n)$).

**Proof.** The result is trivial for perfect fields, and hence for finite fields. Hence we will assume that the ground field $F$ is infinite. If the compositions $(C_{\alpha, \beta}, \vartriangle, n)$ and $(C_{\alpha', \beta'}, \vartriangle, n)$ are isomorphic, any isomorphism $\varphi$ satisfies $n(\varphi(x)) = n(x)$ and $g_{\alpha, \beta}(\varphi(x)) = g_{\alpha', \beta'}(x)$ for any $x$, so $g_{\alpha, \beta}(C_{\alpha, \beta}) = g_{\alpha', \beta'}(C_{\alpha', \beta'})$. Moreover, Lemma 9.17 shows that $F^3 + g_{\alpha, \beta}(C_{\alpha, \beta})$ is a subfield of $F$. If $g_{\alpha, \beta}(C_{\alpha, \beta}) = F^3$, then the elements $x$ and $y$ in the proof of Theorem 12.6 can be taken with $g(x) = 1 = g(y)$, and hence $C_{\alpha, \beta}$ is isomorphic to $C_{1,1}$, which is the split Okubo algebra. If the semilinear map $g_{\alpha, \beta}$ is not bijective, then $\dim_{F^3}(F^3 + g_{\alpha, \beta}(C_{\alpha, \beta}))$ equals 1 or 3, and the dimension of $\ker g_{\alpha, \beta}$ is at least 5. Hence the restriction of the norm to $\ker g_{\alpha, \beta}$ is isotropic, so there exists a hyperbolic pair $a, b$ in $\ker g_{\alpha, \beta}$: $n(a) = n(b) = 0$, $b_\alpha(a, b) = 1$. Take $x$ in $\ker g_{\alpha, \beta}$ with $n(x) \neq 0$. Then $g_{\alpha, \beta}(x \vartriangle x) = n(x)^3$ (Lemma 9.17), so $F^3 \subseteq g_{\alpha, \beta}(C_{\alpha, \beta})$. If $\gamma \in g_{\alpha, \beta}(C_{\alpha, \beta}) \setminus F^3$ and $x \in C_{\alpha, \beta}$ satisfies $g(x) = \gamma$, then we may find $\mu, \nu \in F$.
such that the element $x' = x + \mu a + \nu b$ is isotropic (and satisfies $g(x') = \gamma$). The three-dimensional subspace $\{ z \in C_{\alpha,\beta} \mid x' \triangleleft z = 0, b_n(x', z) = 0 \}$ intersects nontrivially the six-dimensional subspace $g_{\alpha,\beta}^{-1}(F^3)$, so we may take an element

$y'$ satisfying $x' \triangleleft y' = 0, b_n(x', y') = 0$ and $g_{\alpha,\beta}(y') = 1$. The proof of Theorem 12.6 shows that $C_{\alpha,\beta}$ is isomorphic to $C_{\gamma,1}$ for any $0 \neq \gamma \in g_{\alpha,\beta}(C_{\alpha,\beta}) \setminus F^3$.

We are left with the case in which $g_{\alpha,\beta}$ is one-to-one, so $F^3 \cap g_{\alpha,\beta}(C_{\alpha,\beta}) = 0$ and $F^3 + g_{\alpha,\beta}(C_{\alpha,\beta})$ is a field extension of degree 9 of $F^3$. Then, if $g_{\alpha,\beta}(C_{\alpha,\beta}) = g_{\alpha',\beta'}(C_{\alpha',\beta'})$, then both $g_{\alpha,\beta}$ and $g_{\alpha',\beta'}$ are one-to-one, so there is a unique linear map $\phi: C_{\alpha,\beta} \to C_{\alpha,\beta}$ such that $g_{\alpha',\beta'}(x) = g_{\alpha,\beta}(\phi(x))$ for any $x \in C_{\alpha',\beta'}$ (so $\phi = g_{\alpha,\beta}^{-1} g_{\alpha',\beta'}$). Then, by the uniqueness of $\phi$, $C_{\alpha,\beta}$ and $C_{\alpha',\beta'}$ are isomorphic if and only if $\phi$ is an isomorphism. But Lemma 9.17 shows that

$$g_{\alpha,\beta}(\phi(x)^{\Delta 2}) = g_{\alpha,\beta}(\phi(x))^2 + n(\phi(x))^3$$

$$= g_{\alpha',\beta'}(x)^2 + n(\phi(x))^3$$

$$= g_{\alpha',\beta'}(x^{\Delta 2}) - n(x)^3 + n(\phi(x))^3,$$

thus $g_{\alpha,\beta}(\phi(x)^{\Delta 2}) - g_{\alpha',\beta'}(x^{\Delta 2}) \in g_{\alpha,\beta}(C_{\alpha,\beta}) \cap F^3 = 0$ and $\phi(x \triangle x) = \phi(x) \triangle \phi(x)$ for any $x \in C_{\alpha',\beta'}$. This implies, using $(x \triangle x) \triangle x = x \triangle (x \triangle x) = n(x)x$, that $n(\phi(x)) = n(x)$ for any $x \in C_{\alpha',\beta'}$. If $\phi$ is an isomorphism, then $\phi(e_1 \otimes (\alpha')^{\frac{1}{2}}) \triangle \phi(u_1 \otimes (\beta')^{\frac{1}{2}}) = 0$, which is equivalent to $g_{\alpha,\beta}^{-1}(\alpha') \triangle g_{\alpha,\beta}^{-1}(\beta') = 0$.

Conversely, if $\phi(e_1 \otimes (\alpha')^{\frac{1}{2}}) \triangle \phi(u_1 \otimes (\beta')^{\frac{1}{2}}) = 0$, then since the subspaces

$$\{\phi(e_1 \otimes (\alpha')^{\frac{1}{2}}), \phi(e_1 \otimes (\alpha')^{\frac{1}{2}})^{\Delta 2}\}$$

and

$$\{\phi(u_1 \otimes (\beta')^{\frac{1}{2}}), \phi(u_1 \otimes (\beta')^{\frac{1}{2}})^{\Delta 2}\}$$

are orthogonal subspaces of $C_{\alpha,\beta}$, [Eld09, Theorem 3.12] shows that $C_{\alpha,\beta}$ and $C_{\alpha',\beta'}$ are isomorphic. $\square$

In the last part of this section we show that Okubo algebras with isomorphic automorphisms groups (as algebraic groups) are isomorphic or anti-isomorphic (compare with Proposition 8.10). We start with a definition:

**Definition 12.8.** Let $(S, \ast, n_{\mathbf{S}})$ be an Okubo algebra and let $K$ be a 2-dimensional composition subalgebra (i.e., the restriction of $n_{\mathbf{S}}$ to the subalgebra $K$ is nondegenerate). Then $K$ is said to be a regular subalgebra if the para unit of $K \otimes F \mathbf{T}$ is a quadratic idempotent.

**Lemma 12.9.** Let $(C, \Delta, n)$ be the (split) Okubo algebra over an algebraically closed field $F$ (as in Table (5.11)), and let $K$ be a two-dimensional composition subalgebra. Then the following conditions are equivalent:

(i) $K$ is regular.

(ii) There is an automorphism $\varphi$ of $(C, \Delta, n)$ such that $\varphi(K) = Fe_1 + Ff_1$.

(iii) There is another two-dimensional composition subalgebra $K'$ of $(C, \Delta, n)$ orthogonal to $K$: $b_n(K, K') = 0$.

**Proof.** (i)⇒(ii) $K$ is, up to isomorphism, the unique para-quadratic algebra over the algebraically closed field $F$, so there is a basis $\{a, b\}$ of $K$ such that

$\text{DOCUMENTA MATHEMATICA 18 (2013) 413–468}$
\[ a \triangle b = a, b \triangle a = b, a \triangle b = 0 = b \triangle a, \text{ and } n(a) = 0 = n(b), \quad b_\alpha(a, b) = 1. \]

Since \( K \) is regular \( a + a \triangle a = a + b \) is a quadratic idempotent, and by Theorem 9.18 there is an automorphism \( \varphi \) of \( (C, \triangle, n) \) such that \( \varphi(a) = e_1; \)
then \( \varphi(K) = Fe_1 + Ff_1. \)

\[(ii) \Rightarrow (iii) \] This is clear since \( Fu_1 + Fv_1 \) is a two-dimensional composition subalgebra of \( (C, \triangle, n) \) orthogonal to \( Fe_1 + Ff_1. \)

\[(iii) \Rightarrow (i) \] Both \( K \) and \( K' \) are para-quadratic algebras. Take bases \( \{x, x \triangle x\} \)
and \( \{y, y \triangle y\} \) of \( K \) and \( K' \) respectively, with \( n(x) = 0 = n(y) \) and \( b_\alpha(x, x \triangle x) = 1 = b_\alpha(y, y \triangle y). \)
Then [Ekl09, Theorem 3.12] shows that either \( x \triangle y = 0 \)
or \( y \triangle x = 0. \) But \( y \triangle x = 0 \) implies \( x \triangle (y \triangle y) = -y \triangle (y \triangle x) = 0, \)
so replacing \( y \) by \( y \triangle y \) we may assume \( x \triangle y = 0. \) Then by Theorem 9.18
there is an automorphism of \( (C, \triangle, n) \) such that \( \varphi(x) = e_1 \) and \( \varphi(y) = u_1. \)
The para-unit \( x + x \triangle x \) of \( K \) corresponds to \( e_1 + f_1, \) which is a quadratic idempotent.

**Lemma 12.10.** Let \( K \) be a regular two-dimensional composition subalgebra of an Okubo algebra \((S, \ast, n_S).\) Let \( x, y \in K \) be two nonzero elements such that the endomorphism \( \text{ad}_x \ast \text{ad}_y \) is diagonalizable (where \( \text{ad}_z \ast: z \mapsto [x, z] = x \ast z - z \ast x). \)
Then \( n(x) = 0, y \) is a scalar multiple of \( x \ast x, \) and the eigenvalues of \( (\text{ad}_x \ast)^3 \)
are 0, with multiplicity 2, and \( \pm g_S(x), \) each with multiplicity 3. (Recall that \( g_S(x) = b_{\alpha\beta}(x, x \ast x).) \)

**Proof.** Extending scalars to \( \overline{F} \) we may assume by Lemma 12.9 that \((S, \ast, n_S)\)
is the algebra \((C, \triangle, n)\) in Table (5.11) and that \( K = Fe_1 + Ff_1. \) Hence \( x = \alpha e_1 + \beta f_1 \)
and \( y = \alpha' e_1 + \beta' f_1. \) Without loss of generality we may assume \( \alpha \neq 0. \) The subspace \( U = Fu_1 + Fv_2 + Fv_3 \)
is invariant under \( \text{ad}_x \ast \text{ad}_y \ast, \) and the coordinate matrix of the restriction of \( \text{ad}_x \ast \text{ad}_y \ast \)
to \( U \) in the basis \( \{u_1, u_2, u_3\} \) are \( \alpha C - \beta C^2 \) and \( \alpha' C - \beta' C^2 \) where \( C =\begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}. \)
Hence the coordinate matrix of the restriction of \( \text{ad}_x \ast \text{ad}_y \ast \) to \( U \) is
\[
(\alpha C - \beta C^2)(\alpha' C - \beta' C^2) = -((\alpha \beta' + \beta \alpha') I + \beta \beta' C + \alpha \alpha' C^2,
\]
because \( C^3 = I \) (the identity matrix). Therefore we have
\[
(\text{ad}_x \ast \text{ad}_y \ast |_U)^3 = (-\alpha \beta' - \beta \alpha' + \beta \beta' + \alpha \alpha') I = ((\alpha - \beta)(\alpha' - \beta'))^3 I,
\]
and hence \( \text{ad}_x \ast \text{ad}_y \ast |_U - (\alpha - \beta)(\alpha' - \beta') I \) is simultaneously diagonalizable and nilpotent. It follows that \( \text{ad}_x \ast \text{ad}_y \ast |_U \) is a scalar multiple of the identity, so \( \beta \beta' = \alpha \alpha' = 0. \) But \( \alpha \neq 0, \) so \( \alpha' = 0 \) and hence (as \( y \neq 0 \)) \( \beta' \neq 0 \) and \( \beta = 0. \)
Thus \( x = \alpha e_1, y = \beta' f_1, \) and the result follows, since \( (\text{ad}_x \ast)^3 \) acts trivially on \( K, \) by multiplication by \( \alpha \beta' \) on \( U, \) and by multiplication by \( -\alpha^3 \) on \( V = Fu_1 + Fv_2 + Fv_3. \)

Even if the group \( \text{Aut}(S, \ast, n_S) \) is not smooth for an Okubo algebra over a field of characteristic 3, a result corresponding to Proposition 8.10 holds:

**Theorem 12.11.** Let \((S, \ast, n_S)\) and \((S', \ast, n_{S'})\) be two Okubo algebras. The following conditions are equivalent:
(i) The algebraic groups \( \text{Aut}(S, *, n) \) and \( \text{Aut}(S', *, n_{S'}) \) are isomorphic.

(ii) The Lie algebras (see 11.2) \((S, *)^−\) and \((S', *)^−\) are isomorphic. (Here \((S, *)^−\) denotes the Lie algebra defined over \( S \) with bracket \([x, y]^* = x \ast y - y \ast x\).)

(iii) The Okubo algebras \((S, *, n_S)\) and \((S', *, n_{S'})\) are either isomorphic or anti-isomorphic.

Proof. (i)⇒(ii) If the algebraic groups \( \text{Aut}(S, *, n) \) and \( \text{Aut}(S', *, n_{S'}) \) are isomorphic, so are their Lie algebras \( \text{Der}(S, *) \) and \( \text{Der}(S', *) \). But the simple Lie algebra \((S, *)^−\) is isomorphic to the only minimal ideal of \( \text{Der}(S, *) \) [Eld99, Theorem 4], and the same holds for \((S', *)^−\), whence the result.

(iii)⇒(i) This is straightforward.

(ii)⇒(iii) There are nonzero elements \( \alpha, \beta \in F \) such that the Okubo algebra \((S, *, n_S)\) is, up to isomorphism, the Okubo algebra \((C_{\alpha, \beta}, \delta, n)\) (see Theorem 12.6), which is the \( F \)-subalgebra of \((C \otimes F, \delta, n)\) generated by \( x = e_1 \otimes \alpha^+ \) and \( y = u_1 \otimes \beta^+ \). Note that \( x \ast y = 0 \). Then, \((S, *, n_S)\) is graded by \( \mathbb{Z}^3_2 \), with \( \deg(x) = (1,0,0) \) and \( \deg(y) = (0,0,1) \). Therefore \( S = \bigoplus_{\mu \in \mathbb{Z}^3_2} S_\mu \), with \( \dim S_\mu = 1 \) for any nonzero \( \mu \in \mathbb{Z}^3_2 \), \( S_0 = 0 \), and \( S_\mu \ast S_\nu \subseteq S_{\mu + \nu} \). Moreover, for any nonzero \( \mu \in \mathbb{Z}^3_2 \) and any nonzero \( z \in S_\mu \), we have

\[
\begin{align*}
- n_S(z) &= 0, \\
n_{S'}(z) &= Fz \ast z, \\
S_\mu \oplus S_{-\mu} &= \ker \text{ad}_z^* = \{ t \in S \mid t \ast z = z \ast t \}, \text{ and this coincides with the subalgebra } \text{alg}(z) \text{ generated by } z, \text{ and} \\
\bigoplus_{\nu \neq 0, \pm \mu} S_\nu &= \text{the subspace orthogonal to } \text{alg}(z) \text{ relative to } n_S, \\
\text{and coincides with the image of } \text{ad}_z^*.
\end{align*}
\]

Let \( \varphi : (S, *)^− \to (S', *)^− \) be an isomorphism of Lie algebras. Then the Lie algebra \((S', *)^−\) inherits a grading by \( \mathbb{Z}^3_2' \), \( S' = \bigoplus_{\nu \in \mathbb{Z}^3_2} S'_\nu \), with \( S'_\mu = \varphi(S_\mu) \) for any \( \mu \in \mathbb{Z}^3_2 \). Since \( \varphi \) is an isomorphism of Lie algebras, for any nonzero \( \mu \in \mathbb{Z}^3_2 \) and any nonzero \( u \in S'_\mu \), we have

\[
\begin{align*}
- S'_\mu \oplus S'_{-\mu} &= \ker \text{ad}_u^*, \\
\bigoplus_{\nu \neq 0, \pm \mu} S'_\nu &= \text{ad}_u^*(S').
\end{align*}
\]

In particular we have \( (\ker \text{ad}_u^*) \cap \text{ad}_u^*(S') = 0 \). Since \( n_{S'} \) is associative, we get

\[
\begin{align*}
S'_\mu \oplus S'_{-\mu} &= \ker \text{ad}_u^*, \\
\bigoplus_{\nu \neq 0, \pm \mu} S'_\nu &= \text{ad}_u^*(S').
\end{align*}
\]

Now, \( \text{alg}(u) = Fu + Fu \ast u \) is contained in \( \ker \text{ad}_u^* = S'_\mu \oplus S'_{-\mu} \). If \( u \ast u \) were a scalar multiple of \( u \), we would have \( u \ast u = \lambda u \) for some \( 0 \neq \lambda \in F \). But

\[
\begin{align*}
(\text{ad}_u^*)^3 &= (l_u^* - r_u^*)^3 \\
&= (l_u^*)^3 - (r_u^*)^3 \\
&= \lambda^3 l_u^* r_u^* - \lambda^3 r_u^* l_u^* = n_{S'}(u) \text{ Id.}
\end{align*}
\]

But for any \( v \) orthogonal to \( u \),

\[
(l_u^*)^3(v) = u \ast (u \ast (u \ast v)) = -u \ast (v \ast (u \ast u)) = -\lambda u \ast (v \ast u) = -\lambda n_{S'}(u)v.
\]
and also \((r_\nu^*)^3(v) = -\nu n_{S'}(u)v\). Thus \((\text{ad}_u^*)^3(v) = 0\) for any \(v\) orthogonal to \(u\), but this contradicts the fact that \(\ker\text{ad}_u^* \cap \text{ad}_u^*(S') = 0\). We conclude that \(u\) is not a scalar multiple of \(u\) and hence \(\text{alg}(u) = Fu + Fu \ast u = S'_u \oplus S'_{-\mu}\). This shows that \(\text{alg}(u)\) is a regular subalgebra, as we may consider the subalgebra \(S'_\nu \oplus S'_{-\nu}\) for \(\nu \neq 0, \pm \mu\) and use the characterization of regular subalgebras in item (iii) of Lemma 12.9. Finally, for \(0 \neq u \in S'_\mu\) and \(0 \neq v \in S'_{-\mu}\), \(\text{ad}_u^*\text{ad}_u^*(S'_\nu) \subseteq S'_{\mu - \nu + \nu} = S'_\nu\) for any \(\nu \in \mathbb{Z}_3^2\), and this implies that \(\text{ad}_u^*\text{ad}_u^*\) is diagonalizable. By Lemma 12.10 we conclude that \(n_{S'}(u) = 0\), \(v \in Fu \ast u\), and the eigenvalues of \((\text{ad}_u^*)^3\) are \(0\), with multiplicity 2, and \(\pm g_{S'}(u)\), each with multiplicity 3. Take now \(u = \varphi(x) \in S'_0(1,0)\) and \(v = \varphi(y) \in S'_0(0,1)\). Then \(n_{S'}(u) = 0 = n_{S'}(v)\), and
\[
n_{S'}(\text{alg}(u), \text{alg}(v)) = n_{S'}(S'_0(1,0) \oplus S'_0(0,1), S'_0(1,0) \oplus S'_0(0,1)) = 0.
\]
Then \(0 \neq g_{S'}(u) = n_{S'}(u, u \ast u)\) is an eigenvector of \((\text{ad}_u^*)^3\), and hence also of \((\text{ad}_u^*)^3\), so \(g_{S'}(u)\) is either \(g_{S'}(x)\) or \(-g_{S'}(x)\). Also \(g_{S'}(v) = \pm g_{S'}(y)\). Changing \(u\) by \(-u\) and \(v\) by \(-v\) if necessary, we get elements \(u \in S'_0(1,0), v \in S'_0(0,1),\) with \(g_{S'}(u) = g_{S'}(x)\) and \(g_{S'}(v) = g_{S'}(y)\). Now, [Eld09, Theorem 3.12] shows that either \(u \ast v = 0\) or \(v \ast u = 0\), and that \((S'_0, n_{S'})\) and \((S'_0, n_{S'})\) are isomorphic if \(u \ast v = 0\), and anti-isomorphic if \(v \ast u = 0\).

REMARK 12.12. With the notation in Section 12, if \(\dim_{F^3} g_{\alpha, \beta}(C_{\alpha, \beta})\) equals 1 or 3, then \((C_{\alpha, \beta}, \Delta, n)\) and its opposite algebra \((C_{\beta, \alpha}, \Delta, n)\) are isomorphic (see Theorem 12.7). However, if \(\dim_{F^3} g_{\alpha, \beta}(C_{\alpha, \beta})\) is 8, then \((C_{\alpha, \beta}, \Delta, n)\) is not isomorphic to its opposite algebra.

13. Groups admitting triality over arbitrary fields

In this section we classify all simple adjoint groups \(G\) of classical type \(\frac{1}{2}D_4\) which admit triality automorphisms over an arbitrary field \(F\). The first reduction is to groups of type \(\text{PGO}^+(n)\) and \(\text{Spin}(n)\), where \(n\) is a 3-Pfister form. More precisely:

THEOREM 13.1. Let \(F\) be an arbitrary field. Let \(G\) be an adjoint (resp. simply connected) simple group of type \(\frac{1}{2}D_4\) which admits a triality automorphism \(\phi\). There exists a symmetric composition \((S, \ast, n)\) such that the pair \((G, \phi)\) is isomorphic to a pair \((\text{PGO}^+(n), \rho_+)\) (resp. \((\text{Spin}(n), \rho_+))\).

Proof. It suffices to consider the adjoint case. The group \(G\) is a twisted form of \(G_0 = \text{PGO}_3^+(n)\), i.e., there exists a finite field extension \(L/F\) and a cocycle \(\xi \in (G_0 \times \mathbb{Z}/2)(L \otimes L)\) such that
\[
G(F) = \{x \in G_0(L) \mid \xi x_1 = x_2 \xi\}
\]
where \(\mathbb{Z}/2 \hookrightarrow \mathbb{S}_3\) is a fixed embedding and \(x_1, x_2\) are images of \(x\) under two natural mappings \(\pi_i: G_0(L) \to G_0(L \otimes L)\). The isomorphism class of \(G\) is given by the image of the cohomology class \([\xi] \in H^1_{\text{fppf}}(F, G_0 \times \mathbb{Z}/2)\) in \(H^1_{\text{fppf}}(F, G_0 \times \mathbb{S}_3)\). We view \(\phi\) as an element of \((G_0 \times \mathbb{S}_3)(L)\) (as in the proof of Lemma 3.2). The fact that \(\phi\) is \(F\)-defined implies that \(\xi \phi_1 = \phi_2 \xi\).
Replacing if necessary $L$ by a bigger field extension of $F$, we may assume in view of Theorem 7.6 that $\phi$ is conjugate in $(G_0 \rtimes \mathfrak{S}_3)(L)$ to one of the standard trialtarian automorphisms $\beta = \rho_5$ or $\beta = \rho_3$. Let $\beta = \gamma \phi \gamma^{-1}$. Take the cocycle $\xi' = \gamma_2 \xi_1^{-1}$, which is cohomologous to $\xi$. We have

$$\xi' \beta_1 = \gamma_2 \xi_1^{-1} \gamma_1 \phi_1 \gamma_1 = \gamma_2 \xi_1 \gamma_1 = \beta_2 \xi'. $$

Thus replacing $\xi$ by $\xi'$ we may assume that $\phi = \beta$. We now note that by construction $\beta \in \langle G_0 \rtimes \mathfrak{S}_3 \rangle(F)$, hence $\beta_1 = \beta_2 = \beta$ and this implies that $\xi$ takes values in $C_{G_0 \rtimes \mathfrak{S}_3}(\beta) = C_{G_0}(\beta) \rtimes \langle \beta \rangle$. Furthermore, since $G$ has type $1,2, D_4$ the image of the class $[\xi]$ under the projection

$$H^1_{\text{fppf}}(F, G_0 \rtimes \mathfrak{S}_3) \to H^1_{\text{fppf}}(F, \mathfrak{S}_3)$$

takes values in a subgroup of order 2 and on the other hand in the subgroup $\langle \beta \rangle$ of order 3. It follows that $[\xi] \in H^1_{\text{fppf}}(F, H_0)$ where $H_0 = C_{G_0}(\beta)$ is the subgroup of $G_0$ fixed under $\beta$. In view of Lemma 4.7 and Proposition 8.1 the cohomology set $H^1_{\text{fppf}}(F, H_0)$ classifies isomorphism classes of symmetric compositions which over an algebraic closure of $F$ induce trialtarian automorphisms conjugate to $\beta$. The map $H^1_{\text{fppf}}(F, H_0) \to H^1_{\text{fppf}}(F, G_0 \rtimes \mathfrak{S}_3)$ induced by the embedding $H_0 \to G_0 \rtimes \mathfrak{S}_3$ maps the class of the symmetric composition $(S, \star, n)$ to the isomorphism class of the group $\text{PGO}^+(n)$. It follows that $G \cong \text{PGO}^+(n)$ and that our automorphism $\phi$ is of the form $\rho_\star$ for some symmetric composition $\star$ on $S$.

Let $n$ be a 3-Pfister form over $F$ and let $G$ be either $\text{PGO}^+(n)$ or $\text{Spin}(n)$. The next aim is to describe the conjugacy classes of trialtarian automorphisms of $G$. Let $\sigma \in \tilde{G}(F)$ be a trialtarian automorphism of $G$ of order 3. We proved above that $\sigma$ is of the form $\sigma = \rho_\star$ for a proper symmetric composition algebra $(S, \star, n)$ which is either a para-octonion algebra or an Okubo algebra. The fixed subgroup $H = C_G(\langle \sigma \rangle)$ in $G$ is isomorphic to the automorphism group $\text{Aut}(S, \star, n)$, by Proposition 8.1. The group $\tilde{G}$ acts on itself by conjugation and we denote by $X = \text{Cl}_G(\sigma) \subset \tilde{G}$ the orbit of $\sigma$. This is a quasi-projective variety defined over $F$. As we proved before an arbitrary $F$-defined outer automorphism $\phi$ of $G$ whose centralizer in $G$ has the same type as that of $H$ is conjugate to $\sigma$ over an algebraic closure $\overline{F}$ of $F$ and hence $\phi$ can be viewed as an $F$-point of $X$. We denote by $X(F)/\sim$ the set of conjugacy classes of $F$-defined outer automorphisms of $G$ of order 3 whose centralizers have the same type as that of $H$ (equivalently, the set of $\tilde{G}(F)$-orbits in $X(F)$). Let now $\overline{H} = H \times \langle \sigma \rangle \cong C_G(\sigma)$. The group $\tilde{G}$ acts in a natural way on the quotient space $\tilde{G}/\overline{H}$ and by the general formalism of cohomology (see [DG70, p. 372–373]) we have a natural bijection between the set of $\tilde{G}(F)$-orbits in $(\tilde{G}/\overline{H})(F)$ and the set $\text{Ker}[H^1_{\text{fppf}}(F, \overline{H}) \to H^1_{\text{fppf}}(F, \tilde{G})]$. Also, by the universal property of the quotient $\tilde{G}/\overline{H}$ we have a natural $\tilde{G}$-equivariant morphism $\tilde{G}/\overline{H} \to X$ defined over $F$ which induces a bijection $(\tilde{G}/\overline{H})(\overline{F}) \to X(\overline{F})$. 
Consider the commutative diagram

\[
\begin{array}{ccc}
(G/\tilde{H})(F) & \xrightarrow{(G/\tilde{H})(F) \otimes F} & (G/\tilde{H})(F) \\
\lambda & \simeq & \pi_1 \\
X(F) & \xrightarrow{\phi} & X(F) \\
\end{array}
\]

Here \(\pi_1\), \(\pi_2\) (resp. \(\pi'_1\), \(\pi'_2\)) are maps induced by \(a \mapsto a \otimes 1\) and \(a \mapsto 1 \otimes a\) respectively and the top and bottom lines are the diagrams appearing in descent theory. We want to show that \(\lambda\) is a bijection. Let \(x \in X(F)\). Since \(\phi\) is a bijection there exists \(g \in G(F)\) such that \(\phi(g\tilde{H}) = x\). Let \(\theta: (G/\tilde{H})(F) \otimes F \rightarrow (G/\tilde{H})(F)\) (resp. \(X(F) \otimes F \rightarrow X(F)\)) be the bijection corresponding to \(a \otimes b \mapsto b \otimes a\). This is the descent data for the variety \(G/\tilde{H}\) (resp. \(X\) and \(\tilde{G}\)). Since \(x \in X(F)\) we get \(\theta(\pi'_1(x)) = \pi'_2(x)\). Then \(\psi(\theta(\pi_1(g\tilde{H}))) = \psi(\pi'_2(g\tilde{H}))\) and hence \(\psi(\pi_2(g)^{-1}\theta(\pi_1(g))\tilde{H}) = \sigma\). This implies that \(\pi_2(g)^{-1}\theta(\pi_1(g)) \in \tilde{H}(F)\otimes F\) or \(\theta(\pi_1(g)\tilde{H}) = \pi_2(g\tilde{H})\). By descent theory it follows that \(g\tilde{H} \in (G/\tilde{H})(F)\). Thus we have a natural bijection between the set of \(G(F)\)-orbits in \((G/\tilde{H})(F)\) and the set \(X(F)/\sim\). Combining all these facts we obtain

**Theorem 13.2.** There exists a natural bijection between the set of conjugacy classes of \(F\)-defined outer automorphisms of \(G\) of order 3 whose centralizers have the same type as that of \(H\) and the set \(\text{Ker}[H^1_{\text{fppf}}(F, \tilde{H}) \rightarrow H^1_{\text{fppf}}(F, \tilde{G})]\).

Before proceeding with consequences of the theorem we compute the kernel of the last map in terms of the connected groups \(H\) and \(G\).

**Proposition 13.3.** The natural mapping

\[
\lambda: \text{Ker}[H^1_{\text{fppf}}(F, H) \rightarrow H^1_{\text{fppf}}(F, G)] \rightarrow \text{Ker}[H^1_{\text{fppf}}(F, \tilde{H}) \rightarrow H^1_{\text{fppf}}(F, \tilde{G})]
\]

induced by the embedding \(H \hookrightarrow \tilde{H}\) is a bijection.

**Proof.** The mapping \(\lambda\) is induced by the embedding \(H \hookrightarrow \tilde{H} = H \times \langle \sigma \rangle\). Since

\[
H^1_{\text{fppf}}(F, H) \rightarrow H^1_{\text{fppf}}(F, H \times \langle \sigma \rangle)
\]

is clearly injective so is \(\lambda\). As for surjectivity of \(\lambda\), let

\[
\xi \in \text{Ker}[H^1_{\text{fppf}}(F, \tilde{H}) \rightarrow H^1_{\text{fppf}}(F, \tilde{G})].
\]

Since \(\tilde{H} = H \times \langle \sigma \rangle\) we can write \(\xi\) in the form \(\xi = \xi_1 \cdot \xi_2\) where \(\xi_1 \in H^1_{\text{fppf}}(F, H)\) and \(\xi_2 \in H^1_{\text{fppf}}(F, \langle \sigma \rangle)\). The composition \(\tilde{H} \rightarrow \tilde{G} \rightarrow \mathfrak{S}_3\) induces the map

\[
H^1_{\text{fppf}}(F, H \times \langle \sigma \rangle) \rightarrow H^1_{\text{fppf}}(F, \mathfrak{S}_3)
\]

which can be factored through

\[
H^1_{\text{fppf}}(F, \langle \sigma \rangle) \rightarrow H^1_{\text{fppf}}(F, \mathfrak{S}_3)
\]
and the last map has trivial kernel. But it follows from (13.4) that \( \xi_2 \) is in its kernel. Then \( \xi_2 = 1 \) implies \( \xi = \xi_1 \in H_1^{ipf}(F, H) \). It remains to show that \( \xi \) viewed as an element in \( H_1^{ipf}(F, \tilde{G}) \) is trivial. To do this, we look at the exact sequence

\[
1 \rightarrow G \rightarrow \tilde{G} \rightarrow \mathfrak{S}_3 \rightarrow 1
\]

which induces

\[
\tilde{G}(F) \xrightarrow{\mu_1} \mathfrak{S}_3(F) \rightarrow H_1^{ipf}(F, G) \xrightarrow{\mu_2} H_1^{ipf}(F, \tilde{G}).
\]

Surjectivity of \( \mu_1 \) implies that the kernel of \( \mu_2 \) is trivial. Since by our construction the cocycle \( \xi \) viewed as an element in \( H_1^{ipf}(F, \tilde{G}) \) is trivial, it is also trivial as an element in \( H_1^{ipf}(F, G) \). Thus we proved that \( \xi \) is in \( \text{Ker}\left[H_1^{ipf}(F, H) \rightarrow H_1^{ipf}(F, G)\right] \) and we are done. \( \square \)

In the next corollaries we describe explicitly the set

\[ \text{Ker}\left[H_1^{ipf}(F, H) \rightarrow H_1^{ipf}(F, G)\right] \]

where \( F \) is an arbitrary field. In view of 13.2 and 13.3 this leads to a complete list of conjugacy classes of trialitarian automorphisms of \( G \). Clearly, the description depends on the structure of the algebraic group \( H \) in question. We recall that this group is the automorphism group of a symmetric composition algebra of dimension 8. Each corollary corresponds to one of the types of symmetric algebras described in Section 8. We recall that we have para-octonion algebras (Type I), Okubo algebras in characteristic different from 3 (Type IIa and Type IIb), which are obtained from central simple algebras of degree 3, and Okubo algebras in characteristic 3 (Type III). In each case the trialitarian automorphisms are those linked to symmetric compositions, as described in Theorem 4.8.

**Corollary 13.5.** Let \( F \) be an arbitrary field. Let \( n \) be a 3-Pfister form over \( F \) and let \( G = \text{PGO}^{-4+8}(n) \) or \( G = \text{Spin}(n) \). Then there is a unique conjugacy class of trialitarian \( F \)-automorphisms of \( G \) whose centralizers in \( G \) have type \( G_2 \). The class is represented by the trialitarian automorphism \( \rho_o \) associated to the isomorphism class of the para-octonion algebra with norm \( n \).

**Proof.** Let \( \sigma \) be an \( F \)-defined trialitarian automorphism of \( G \) with the property \( H = C_G(\sigma) = G_2(n) \) where \( G_2(n) \) is the automorphism group of an octonion algebra with norm \( n \). By Proposition 8.3 the map \( H_1^{ipf}(F, H) \rightarrow H_1^{ipf}(F, G) \) is injective. The result now follows from Theorem 13.2 and Proposition 13.3. \( \square \)

The next corollary corresponds to the case where the algebraic group \( H \) is the group of automorphisms of the split Okubo algebra over a field of characteristic not 3 containing a primitive cube root of unity, hence \( H \) is the split group \( \text{PGL}_3 \).

**Corollary 13.6.** Let \( F \) be an arbitrary field of characteristic different from 3 and assume that a primitive cube root of unity \( \omega \) is contained in \( F \). Let \( G = \text{PGO}_8^* \). Then the set of conjugacy classes of trialitarian \( F \)-automorphisms of
G whose centralizers in G have type A2 is in one-to-one correspondence with the set of isomorphism classes of central simple algebras over F of degree 3.

Proof. We apply Theorem 13.2 and Proposition 13.3 with σ the standardtrialitarian automorphism π, associated to the split Okubo multiplication. Its centralizer H in G is PGL3, hence \( H^1_{\text{fppf}}(F, H) \) classifies central simple algebras over F of degree 3. Also, it is clear that \( H^1_{\text{fppf}}(F, H) \to H^1_{\text{fppf}}(F, G) \) is a trivial mapping because on one side every element in \( H^1_{\text{fppf}}(F, H) \) is split by a cubic extension of F and, on the other side, no element in \( H^1_{\text{fppf}}(F, G) \) is split by a cubic extension, in view of Springer’s Theorem (see for instance [Sch85, Theorem 5.4]). The result now follows from Theorem 13.2 and Proposition 13.3. \( \square \)

Remark 13.7. Tracing through our constructions, we can make the correspondence of Corollary 13.6 explicit as follows, using Galois homology since the characteristic of F is not 3. Let \( \rho \) be the standard trialitarian automorphism associated to the split Okubo multiplication over F. Its centralizer in \( G = \text{PGO}^8_3 \) is a split group PGL3. Let \( \rho \) be another trialitarian automorphism over F whose centralizer is a group of type A2. We may view \( \rho_\gamma \) and \( \rho \) as elements of the group \( (\text{PGO}^8_3 \times \text{G}_3)(F) \). We know that they are conjugate over a separable closure \( F_{\text{sep}} \) of F by an element of \( \text{PGO}^8_3 \). Let \( g \in \text{PGO}^8_3(F_{\text{sep}}) \) be such that \( \rho = g\rho_\gamma g^{-1} \). For \( \gamma \in \text{Gal}(F_{\text{sep}}/F) \) we have \( \rho_\gamma = \rho \) and \( \rho_\gamma^1 = \rho_\gamma \) since \( \rho \) and \( \rho_\gamma \) are defined over F, hence \( (g_\gamma)^{-1}g \) lies in the centralizer of \( \rho_\gamma \) in \( \text{PGO}^8_3 \). Thus we get a cocycle \( a_\gamma = (g_\gamma)^{-1}g \in Z^1(F, \text{PGL}_3) \). This cocycle gives rise to a central simple algebra, say \( A \), of degree 3 over F. Note that it follows from the construction that the group \( \text{PGL}(A) \) is the centralizer of \( \rho \) in \( \text{PGO}^8_3 \).

Conversely, assume that we have a central simple algebra A of degree 3 over F. It is determined by a cocycle \( a_\gamma \) with coefficients in \( \text{PGL}_3 \). Since the map \( H^1(F, \text{PGL}_3) \to H^1(F, \text{PGO}^8_3) \) is trivial (as observed in the proof of Corollary 13.6), there exists \( g \in \text{PGO}^8_3(F_3) \) such that \( a_\gamma = (g_\gamma)^{-1}g \). Consider \( \rho = g\rho_\gamma g^{-1} \). Since \( \rho_\gamma \) is defined over F and \( (g_\gamma)^{-1}g \) centralizes \( \rho_\gamma \) for all \( \gamma \), it follows that \( \rho \) is defined over F.

Similar considerations apply to corollaries 13.8 and 13.9 below.

Now, suppose the field F does not contain \( \omega \), and char \( F \neq 3 \). Let \( K = F(\omega) \), which is a quadratic field extension of F. Before stating the next corollary we recall that on a given central simple K-algebra B of degree 3, unitary involutions \( \tau \) fixing F are classified by a quadratic form invariant \( \pi(\tau) \), which is a 3-Pfister form over F split by K, see [KMRT98, (19,6)]. This result is proved in [KMRT98] under the hypothesis that char \( F \neq 2 \), but the following observations show that it also holds when char \( F = 2 \).

If \( \text{char} F \neq 2 \), the 3-fold Pfister form \( \pi(\tau) \) is obtained by modifying the form \( Q_\tau(x) = \text{Trd}(x^2) \) defined on the F-vector space Sym(\( \tau \)) of \( \tau \)-symmetric elements: see [KMRT98, (19.4)]. The arguments in the proof of the classification theorem [KMRT98, (19.6)] can be used when char \( F = 2 \), substituting for \( Q_\tau \) the restriction to Sym(\( \tau \)) of the quadratic form \( \text{Sr}(x) \), which is the
coefficient of the indeterminate $t$ in the reduced characteristic polynomial of $x$ (as in Proposition 8.5). Let $\varphi_\tau$ be the restriction of $Srd$ to the $F$-vector space $\text{Sym}(\tau)^0$ of $\tau$-symmetric elements of trace zero, and let $[1,1]$ denote the quadratic form $X^2 + XY + Y^2$ over $F$. If $B$ is split and $\tau$ is adjoint to a hermitian form $h$ with diagonalization $\langle \delta_1, \delta_2, \delta_3 \rangle_K$, computation shows that $\varphi_\tau \cong [1,1] \perp \langle \delta_1 \delta_2, \delta_2 \delta_3, \delta_3 \delta_1 \rangle \cdot n_K$, where $n_K$ is the norm form of $K/F$. Therefore, if $\tau'$ is also a unitary involution on the split algebra $B$, and $\tau'$ is adjoint to a hermitian form $h'$, the arguments on [KMRT98, p. 305] show that $\varphi_{\tau'} \cong \varphi_\tau$ implies $h'$ is similar to $h$, hence $\tau'$ and $\tau$ are isomorphic. Therefore, the 3-fold Pfister form $\pi(\tau) = \langle 1, \delta_1 \delta_2, \delta_2 \delta_3, \delta_3 \delta_1 \rangle \cdot n_K$ determines the involution $\tau$ up to isomorphism. The case where $B$ is not split reduces to the split case by an odd-degree scalar extension. The arguments on p. 305 of [KMRT98] apply in characteristic 2, since [KMRT98, (6.17)] relies on a result of Bayer-Lenstra that also holds in characteristic 2 (see [BFT07, Theorem 1.13] for a discussion of the Bayer-Lenstra result in characteristic 2).

**Corollary 13.8.** Let $F$ be an arbitrary field of characteristic not 3 and assume that $F$ does not contain a primitive cube root of unity $\omega$. Let $n$ be a 3-Pfister form split by $K = F(\omega)$ and let $G$ be $\text{PGO}^+(n)$ or $\text{Spin}(n)$. Then the set of conjugacy classes of trialitarian $F$-automorphisms of $G$ of order 3 whose centralizers in $G$ have type $A_2$ is in one-to-one correspondence with the set of $F$-isomorphism classes of pairs $(B, \tau)$ where $B$ is a central simple $K$-algebra of degree 3 and $\tau$ is a unitary involution on $B$ fixing $F$ such that $\pi(\tau) = n$.

**Proof.** Let $\sigma$ be an outer $F$-automorphism of $G$ of order 3 whose centralizer $H$ in $G$ is an outer form of type $^2A_2$, of inner type over $K$. Its existence follows from our previous results. Indeed, take the standard trialitarian automorphism $\rho_0$ of $G$ corresponding to the para-octonion algebra $(C, \cdot, n)$ with norm $n$. Its automorphism group has type $G_2$ and splits over $K = F(\omega)$. Hence it contains a subtorus of the form $R_K^{(1)}(\mathbb{G}_m)$. Such a torus contains an element of order 3 over $F$, namely $\omega$. Twisting the multiplication $\cdot$ by $\omega$ we get an Okubo algebra $(C, \cdot_\omega, n)$. The corresponding automorphism $\rho_{\omega}$ of $G$ is as required.

Let $H_0$ be an adjoint quasi-split $F$-group of type $^2A_2$, of inner type over $K$. It is known that $H$ is a twisted form of $H_0$, i.e. $H = \xi H_0$ where $\xi \in Z^1(F,H_0)$. Also, we know that the pointed set $H^{1}_{\text{ppf}}(F,H_0)$ classifies pairs $(B, \tau)$ where $B$ is a central simple algebra over $K$ of degree 3 and $\tau$ is a unitary involution on $B$ (see [KMRT98, (30.21)]) and that there exists a natural bijection $H^1(F,H_0) \to H^1(F,H)$ which takes the class $[\xi]$ into the trivial class. Thus the pointed set $H^{1}_{\text{ppf}}(F,H)$ also classifies the same pairs $(B, \tau)$. The mapping $H^{1}_{\text{ppf}}(F,H) \to H^{1}_{\text{ppf}}(F,G)$ takes a pair $(B, \tau)$ to the class in $H^{1}_{\text{ppf}}(F,G)$ corresponding to the 3-Pfister form $\pi(\tau)$ (see [KMRT98, §30.C]). So the result follows from Theorem 13.2 and Proposition 13.3. \qed
Finally, suppose \( \text{char } F = 3 \). If the centralizer \( H \) of a trialitarian automorphism \( \phi \) is not a form of type \( G_2 \), this centralizer is the automorphism group of an Okubo algebra, as computed in Section 10.

**Corollary 13.9.** Let \( G = \mathbf{PGO}_8^+ \) be defined over an arbitrary field \( F \) of characteristic 3. The set of conjugacy classes of trialitarian \( F \)-automorphisms of \( G \) of Okubo type in \( G \) is in one-to-one correspondence with the set of isomorphism classes of Okubo algebras over \( F \).

**Proof.** Taking Theorem 12.6 into account, the proof is along the same lines as the proof of Corollary 13.6. \( \square \)

Abstract. A collection of \( n \) distinct hyperplanes \( L_i = \{ l_i = 0 \} \subset \mathbb{P}^{n-1} \), the \((n-1)\)-dimensional projective space over an algebraically closed field of characteristic not equal to 2, is a polar simplex of a smooth quadric \( Q^{n-2} = \{ q = 0 \} \), if each \( L_i \) is the polar hyperplane of the point \( p_i = \bigcap_{j \neq i} L_j \), equivalently, if \( q = l_1^2 + \ldots + l_n^2 \) for suitable choices of the linear forms \( l_i \). In this paper we study the closure \( VPS(Q, n) \subset \text{Hilb}_n(\mathbb{P}^{n-1}) \) of the variety of sums of powers presenting \( Q \) from a global viewpoint: \( VPS(Q, n) \) is a smooth Fano variety of index 2 and Picard number 1 when \( n < 6 \), and \( VPS(Q, n) \) is singular when \( n \geq 6 \).

1. Introduction

Let \( Q = \{ q = 0 \} \) be a \((n - 2)\)-dimensional smooth quadric defined over the complex numbers, or any algebraically closed field of characteristic not equal to 2. We denote the projective space containing \( Q \) by \( \mathbb{P}^{n-1} \) because its dual space \( \mathbb{P}^{n-1} \) plays the major role in this paper. A collection \( L_1 = \{ l_1 = 0 \}, \ldots, L_n = \{ l_n = 0 \} \) of \( n \) hyperplanes is a polar simplex iff each \( L_i \) is the polar of the point \( p_i = \bigcap_{j \neq i} L_j \), equivalently, iff the quadratic equation

\[
q = \sum_{i=1}^{n} l_i^2
\]

holds for suitable choices of the linear forms \( l_i \) defining \( L_i \). In this paper we study the collection of polar simplices, or equivalently, the variety of sums of powers presenting \( q \) from a global viewpoint.

We may regard a polar simplex as a point in \( \text{Hilb}_n(\mathbb{P}^{n-1}) \). Let \( VPS(Q, n) \subset \text{Hilb}_n(\mathbb{P}^{n-1}) \) be the closure of the variety of sums of \( n \) squares presenting \( Q \).

The first main result is:

**Theorem 1.1.** If \( 2 \leq n \leq 5 \), then \( VPS(Q, n) \) is a smooth rational \( \binom{n}{2} \)-dimensional Fano variety of index 2 and Picard number 1. If \( n \geq 6 \), then \( VPS(Q, n) \) is a singular rational \( \binom{n}{2} \)-dimensional variety.

If \( n = 2 \), then \( VPS(Q, n) = \mathbb{P}^1 \), and if \( n = 3 \), then \( VPS(Q, n) \) is a rational Fano threefold of index 2 and degree 5 (cf. [Muk92]).

The quadratic form defines a collineation \( q : \mathbb{P}^{n-1} \to \mathbb{P}^{n-1} \), let \( q^{-1} : \mathbb{P}^{n-1} \to \mathbb{P}^{n-1} \) be the inverse collineation, and \( Q^{-1} = \{ q^{-1} = 0 \} \subset \mathbb{P}^{n-1} \) the corresponding quadric. Consider the double Veronese embedding \( Q^{-1} \to \mathbb{P}(\binom{n+1}{2} - 2) \), and let \( TQ^{-1} \) be the image by the Gauss map of tangent spaces \( Q^{-1} \to \mathbb{G}(n - 1, \binom{n+1}{2} - 1) \). Our second main result is:

**Theorem 1.2.** \( VPS(Q, n) \) has a natural embedding in the Grassmannian variety \( \mathbb{G}(n - 1, \binom{n+1}{2} - 1) \) and contains the image \( TQ^{-1} \) of the Gauss map of the quadric \( Q^{-1} \) in its Veronese embedding. When \( n = 4 \) or \( n = 5 \), the restriction of the Plicker bundle generates the Picard group of \( VPS(Q, n) \), and the degree is 310, resp. 395780.

We denote the coordinate ring of \( \mathbb{P}^{n-1} \) by \( S = \mathbb{C}[x_1, \ldots, x_n] \) and the coordinate ring of the dual \( \mathbb{P}^{n-1} \) by \( T = \mathbb{C}[y_1, \ldots, y_n] \). In particular \( S_1 = (T_1)^* \), so we may set \( \mathbb{P}^{-1} = \mathbb{P}(T_1) \), the projective space of 1-dimensional subspaces of \( T_1 \) with coordinate functions in \( S \), and \( \mathbb{P}^{-1} = \mathbb{P}(S_1) \) with coordinate functions in \( T \). Let \( q \in T = \mathbb{C}[y_1, \ldots, y_n] \) be a quadratic form defining the smooth \((n - 2)\)-dimensional quadric \( Q \subset \mathbb{P}^{n-1} = \mathbb{P}(S_1) \). Regard \( [q] \) as a point in \( \mathbb{P}(T_2) \) and consider the Veronese variety \( V_2 \subset \mathbb{P}(T_2) \) of squares,

\[
V_2 = \{ [l^2] \in \mathbb{P}(T_2) | l \in \mathbb{P}(T_1) \}.
\]

Then a polar simplex to \( Q \) is simply a collection of \( n \) points on \( V_2 \) whose linear span contains \([q]\). Any length \( n \) subscheme \( \Gamma \subset V_2 \) whose span in \( \mathbb{P}(T_2) \)
contains \([q]\) is called an apolar subschemes of length \(n\) to \(Q\). The closure \(VPS(Q, n)\) of the polar simplices in \(\text{Hilb}_n(\mathbb{P}(T_1))\) consists of apolar subschemes of length \(n\). We denote by \(VAPS(Q, n)\) the subset of \(\text{Hilb}_n(\mathbb{P}(T_1))\), with reduced scheme structure, parameterizing all apolar subschemes of length \(n\) to \(Q\). Our third main result is:

**Theorem 1.3.** The algebraic set \(VAPS(Q, n)\) is isomorphic to the complete linear section

\[ VAPS(Q, n) = \langle TQ^{-1} \rangle \cap G(n - 1, T_2/q) \subset \mathbb{P}({\wedge}^{n-1}(T_2/q)) \]

in the Plücker space. For \(n \leq 6\) the two subschemes \(VPS(Q, n)\) and \(VAPS(Q, n)\) coincide. For \(n \geq 24\), the scheme \(VAPS(Q, n)\) has more than one component.

Notice that we do not claim that the linear section \(\langle TQ^{-1} \rangle \cap G(n - 1, T_2/q)\) is reduced, only that its reduced structure coincides with \(VAPS(Q, n)\). The linear span \(\langle TQ^{-1} \rangle\) has dimension \(\binom{2n-1}{n-1} - \binom{2n-3}{n-2} - 1\), while the Grassmannian has dimension \((n - 1)\binom{n}{2} - (\binom{n+1}{2} - 1)\)-dimensional Plücker space. So this linear section is far from a proper linear section when \(n \geq 4\), i.e. the codimension of \(VAPS(Q, n)\) in the Grassmannian is much less than the codimension of its linear span in the Plücker space.

We find a covering of \(VAPS(Q, n)\) by affine subschemes \(V^{{\text{aff}}}h(n)\) that are contractible to a point \([p] \in VPS(Q, n)\) (Lemma 5.3). Therefore the apolar subschemes \(\Gamma_p\) play a crucial point. Let us explain what they are: The projection of the Veronese variety \(V_2 \subset \mathbb{P}(T_2)\) from \([q] \in \mathbb{P}(T_2)\) is a variety \(V_{2,q} \subset \mathbb{P}(T_2/q)\). Since a polar simplex to \(Q\) is a collection on \(n\) points on \(V_2\) whose span contains \([q]\), the variety \(V^{SP}(Q, n)\) is naturally embedded in and in fact coincides with the variety of \((n - 2)\)-secant spaces of the projected Veronese variety \(V_{2,q}\). The double Veronese embedding of \(Q^{-1}\) is a linearly normal subvariety in \(V_{2,q}\) that spans \(\mathbb{P}(T_2/q)\). For each point \(p \in Q^{-1}\) consider the tangent space to \(Q^{-1}\) in this embedding. This tangent space intersects \(V_{2,q}\) along the subscheme \(\Gamma_p\), and belong to the boundary of variety of \((n - 2)\)-secant spaces of \(V_{2,q}\).

The affine subscheme \(V_h^{{\text{aff}}}n\) is contractible to \(\Gamma_p\), but depend only on a hyperplane: It consists of the apolar subschemes that do not intersect a tangent hyperplane \(h\) to \(Q^{-1}\). The point \(p\) is simply a point on \(Q^{-1}\) that does not lie in this hyperplane.

Our computations show that the affine scheme \(V_h^{{\text{aff}}}n\) and certain natural subschemes has particularly interesting structure: \(V_h^{{\text{aff}}}n\) is isomorphic to an affine space when \(n < 6\) while \(V_h^{{\text{aff}}}(6)\) is isomorphic to a 15-dimensional spinor variety (Corollary 5.16). Why this spinor variety appears is quite mysterious to us. Recall that Mukai showed that a general canonical curve of genus 7 is a linear section of the spinor variety. Let \(V^{{loc}}_p(n) \subset VAPS(Q, n)\) be the subscheme of apolar subschemes in \(VAPS(Q, n)\) with support at a single point \(p \in Q^{-1}\). The subscheme \(V^{{loc}}_p(n)\) is naturally contained in \(V^{{sec}}_p(n)\), the variety of apolar subschemes in \(V_h^{{aff}}(n)\) that contains
the point \( p \). We compute these subschemes with Macaulay2 [GS] when \( n < 6 \) and find that \( V_{\text{loc}}(5) \) is isomorphic to a 3-dimensional cone over the tangent developable of a rational normal sextic curve. This cone is a codimension 3 linear section of the scheme \( V_{\text{sec}}(5) \), which is isomorphic to a 6-dimensional cone over the intersection of the Grassmannian \( G(2, 5) \) with a quadric. Mukai showed that a general canonical curve of genus 6 is a linear section of the intersection of \( G(2, 5) \) with a quadric. The appearances in the cases \( n = 5, 6 \) of a natural variety whose curve sections are canonical curves is both surprising and unclear to us. The computational results are summarized in Table 1 in Section 5.

By the very construction of polar simplices, it is clear that \( \text{VPS}(Q, n) \) has dimension \( \binom{n}{2} \). On the other hand, the special orthogonal group \( SO(n, q) \) that preserves the quadratic form \( q \), acts on the set of polar simplices: If we assume that the symmetric matrix of \( q \) with respect to the variables in \( T \) is the identity matrix, then regarding \( SO(n, q) \) as orthogonal matrices the rows define a polar simplex. Matrix multiplication therefore defines a transitive action of \( SO(n, q) \) on the set of polar simplices. By dimension count, this action has a finite stabilizer at a polar simplex. This stabilizer is the subgroup \( H \subset SO(n, q) \) of rotational symmetries of the hypercube \([-1, 1]^n \subset \mathbb{R}^n\) of order \( 2^{n-1} \cdot n! \) as suggested by an anonymous referee. We get

**Proposition 1.4.** \( \text{VPS}(Q, n) \) is a compactification of the group \( SO(n, q)/H \).

The linear representation of \( SO(n, q) \) on \( T_2 \) decomposes

\[
T_2 = \langle q \rangle \oplus T_{2,q},
\]

where the hyperplane \( \text{P}(T_{2,q}) \) intersect the Veronese variety \( V_2 \) along the Veronese image of \( Q^{-1} \). Therefore we may identify \( T_2/q = T_{2,q} \) and the projection from \( [q]; \text{P}(T_2) \rightarrow \text{P}(T_{2,q}) \) is an \( SO(n, q) \)-equivariant projection. \( Q^{-1} \subset \text{P}(T_{2,q}) \) is a closed orbit, and similarly the image \( TQ^{-1} \) of the Gauss map is a closed orbit for the induced representation on the Plücker space of \( G(n - 1, T_{2,q}) \). The linear span of this image is therefore the projectivization of an irreducible representation of \( SO(n, q) \). The set of polar simplices form an orbit for the action of \( SO(n, q) \), so the linear span of \( \text{VPS}(Q, n) \) is also the projectivization of an irreducible representation of \( SO(n, q) \). Therefore

\[
\text{VPS}(Q, n) \subset \langle TQ^{-1}\rangle \cap G(n - 1, T_{2,q}).
\]

We show that the intersection \( \langle TQ^{-1}\rangle \cap G(n - 1, T_{2,q}) \) parameterizes all apolar subschemes of length \( n \), hence Theorem 1.1.

The organization of the paper follows distinct approaches to \( \text{VPS}(Q, n) \). To start with we introduce the classical notion of apolarity and regard polar simplices as apolar subschemes in \( \text{P}(T_1) \) of length \( n \) with respect to \( q \). We use syzygies to characterize these subschemes among elements of the Hilbert scheme. In fact, polar simplices are characterized by their smoothness, the Betti numbers of their resolution, and their apolarity with respect to \( q \). Allowing singular subschemes, we consider all apolar subschemes of length \( n \). We show in Section 2 that these subschemes naturally appear in the closure \( \text{VPS}(Q, n) \) of the
set of polar simplices in the Hilbert scheme. For \( n > 6 \) there may be apolar subschemes of length \( n \) that do not belong to the closure \( VPS(Q, n) \) of the smooth ones. In fact, we show in Section 2 that at least for \( n \geq 24 \), there are nonsmoothable apolar subschemes of length \( n \), i.e. that \( VPS(Q, n) \) is not the only component of \( VAPS(Q, n) \).

The variety \( VPS(Q, n) \), in its embedding in \( G(n - 1, T_{2,q}) \), has order one, i.e. through a general point in \( P(T_{2,q}) \) there is a unique \((n - 2)\)-dimensional linear space that form the span of an apolar subscheme \( \Gamma \) of length \( n \). This is a generalization of the fact that a general symmetric \( n \times n \) matrix has \( n \) distinct eigenvalues. In Section 3 we use a geometric approach to characterize the generality assumption.

The fact that \( VPS(Q, n) \) has order one, means that it is the image of a rational map

\[
\gamma : P(T_{2,q}) \to G(n - 1, T_{2,q}).
\]

In Section 4 we use a trilinear form introduced by Mukai to give equations for the map \( \gamma \). With respect to the variables in \( T \) we may associate a symmetric matrix \( A \) to each quadratic form \( q' \in T_{2,q} \). The Mukai form associates to \( q' \) a space of quadratic forms in \( S_{2} \) that vanish on all the projectivized eigenspaces of the matrix \( A \). For general \( q' \) these quadratic forms generate the ideal of the unique common polar simplex of \( q \) and \( q' \). This is Proposition 4.2. The Mukai form therefore defines the universal family of polar simplices, although it does not extend to the whole boundary. Common apolar subschemes to \( q \) and \( q' \), when \( q' \) has rank at most \( n - 2 \), form the exceptional locus of the map \( \gamma \).

We do not compute the image of \( \gamma \) in \( G(n - 1, T_{2,q}) \). Instead we compute affine perturbations of \([\Gamma_{p}]\) in \( G(n - 1, T_{2,q}) \) that correspond to apolar subschemes to \( Q \). These perturbations form the affine subschemes \( V_{h}^{n\text{aff}}(n) \) that cover \( VAPS(Q, n) \). In Section 5 we make extensive computations of these affine subschemes. Each one of them is contractible to a point \( [\Gamma_{p}] \) on the subvariety \( TQ^{-1} \subset VPS(Q, n) \). The question of smoothness of \( VPS(Q, n) \) is reduced to a question of smoothness of the affine scheme \( V_{h}^{n\text{aff}}(n) \) at the point \( [\Gamma_{p}] \). For \( n \leq 5 \) we show that such a point is smooth, while for \( n \geq 6 \), it is singular. The main result of Section 5 is however Theorem 1.3, that \( VAPS(Q, n) \) is a linear section of the Grassmannian.

In the final Section 6 we return to the geometry of \( VPS(Q, n) \) and compute the degree by a combinatorial argument for any \( n \). The Fano-index is computed using the natural \( P^{n-2} \)-bundle on \( VPS(Q, n) \), obtained by restricting the incidence variety over the Grassmannian, and its birational morphism to \( P(T_{2,q}) \).

We thank Tony Iarrobino for sharing his insight on Artinian Gorenstein rings with us, Francesco Zucconi for valuable comments on a previous version of this paper.

Let us briefly summarize the notation:

- \( \mathbb{C} \) denotes the field of complex numbers.
• $q \in T_2$ is a non-degenerate quadratic form, and defines a collineation $q : S_1 \to T_1$ and a linear form $q : S_2 \to \mathbb{C}$.
• $Q$ is the quadratic hypersurface \{ $q = 0$ \} $\subseteq \mathbb{P}(S_1)$.
• $q^{-1} \in S_2$ is a quadratic form, that defines the collineation $q^{-1} : T_1 \to S_1$ inverse to $q$ and a linear form $q^{-1} : T_2 \to \mathbb{C}$.
• $Q^{-1}$ is the quadratic hypersurface \{ $q^{-1} = 0$ \} $\subseteq \mathbb{P}(T_1)$.
• $q^2 \subseteq S_2$ is the kernel of the linear form $q : S_2 \to \mathbb{C}$.
• $T_{2,q}$ is the kernel $(q^{-1})^2$ of the linear form $q^{-1} : T_2 \to \mathbb{C}$.
• $\pi_q : \mathbb{P}(T_2) \dashrightarrow \mathbb{P}(T_{2,q})$ is the projection from $[q] \in \mathbb{P}(T_2)$, and $V_{2,q} \subseteq \mathbb{P}(T_{2,q})$ is the image under this projection of the Veronese variety $V_2 \subseteq \mathbb{P}(T_2)$.

2. Apolar subschemes of length $n$

We follow the approach of [RS00]: The apolarity action is defined as the action of $S = \mathbb{C}[x_1, \ldots, x_n]$ as polynomial differential forms on $T = \mathbb{C}[y_1, \ldots, y_n]$ by setting $x_i = \frac{\partial}{\partial y_i}$. This makes the duality between $S_1$ and $T_1$ explicit and, in fact, defines a natural duality between $T_1$ and $S_1$. The form $q \in T_2$ define the smooth $(n - 2)$-dimensional quadric hypersurface

$$Q = \{ \left( \sum a_i x_i \right) | \left( \sum a_i \frac{\partial}{\partial y_i} \right)^2(q) = 0 \} \subseteq \mathbb{P}(S_1).$$

Apolarity defines a graded Artinian Gorenstein algebra associated to $Q$:

$$A^Q = \mathbb{C}[x_1, \ldots, x_n]/(q^\perp)$$

where

$$q^\perp = \{ D \in S_2 = \mathbb{C}[x_1, \ldots, x_n]_2 | D(q) = 0 \}.$$

A subscheme $Y \subseteq \mathbb{P}(T_1)$ is apolar to $Q$, or equivalently apolar to $q$, if the space of quadratic forms in its ideal $I_{Y,2} \subseteq q^\perp$. The apolarity lemma (cf. [RS00] 1.3) says that any smooth $\Gamma$, $[\Gamma] \in \text{Hilb}_n(\mathbb{P}(T_1))$ is a polar simplex with respect to $Q \subseteq \mathbb{P}(S_1) = \mathbb{P}^{n-1}$ if and only if $I_{\Gamma,2} \subseteq q^\perp \subseteq S_2$, i.e. $\Gamma$ is apolar to $Q$. We drop, for the moment, the smoothness criterion and consider any $[\Gamma] \in \text{Hilb}_n(\mathbb{P}(T_1))$, such that $\Gamma$ is apolar to $Q$. Notice that since $Q$ is nonsingular, $\Gamma$ is nondegenerate. But more is known: The following are the graded Betti numbers of $A^Q$ and $\Gamma$, given in Macaulay2 notation [GS].

**Proposition 2.1.** a) For a smooth quadric $Q \subseteq \mathbb{P}^{n-1}$ the syzygies of the apolar Artinian Gorenstein ring $A^Q$ are

$$1 \quad - \quad - \quad - \quad - \quad - \quad - \quad -$$

$$- \quad - \quad \frac{n-1}{n+1} \binom{n+2}{2} \quad \cdots \quad \frac{k(n-k)}{n+1} \binom{n+2}{k+1} \quad \cdots \quad \frac{n-1}{n+1} \binom{n+2}{n} \quad -$$

$$- \quad - \quad \cdots \quad - \quad \cdots \quad - \quad - \quad 1$$

b) A zero-dimensional nondegenerate scheme $\Gamma \subseteq \mathbb{P}^{n-1}$ of length $n$ has syzygies

$$1 \quad - \quad - \quad - \quad - \quad - \quad -$$

$$- \quad - \quad \binom{n}{2} \quad \cdots \quad k \binom{n}{k+1} \quad \cdots \quad (n-1) \binom{n}{n} \quad -$$

**Proof.** Eg. [Beh81] and [ERS81]
Corollary 2.2. The natural morphism

\[ VAPS(Q, n) \to \mathcal{G}(\binom{n}{2}, q^\perp); \quad \Gamma \mapsto I_{\Gamma, 2} \subset q^\perp \]

is injective. Equivalently, there is a natural injective morphism

\[ VAPS(Q, n) \to \mathcal{G}(n-1, T_{2,q}); \quad \Gamma \mapsto I_{\Gamma, 2}^2 \subset T_{2,q} \]

into the variety of \((n-2)\)-dimensional subspaces of \(\mathbf{P}(T_{2,q})\) that intersect the projected Veronese variety \(V_{2,q}\) in a scheme of length \(n\). In particular, the Hilbert scheme and Grassmannian compactification in \(\mathcal{G}(n-1, T_{2,q})\) of the variety of polar simplices coincide.

Proof. Apolarity defines a natural isomorphism \(q^\perp \cong T_{2,q}^\perp\). Therefore the subspace \(I_{\Gamma, 2} \subset q^\perp\) defines a \((n-1)\)-dimensional subspace \(I_{\Gamma, 2}^2 \subset T_{2,q}\). The intersection \(P(I_{\Gamma, 2}^2) \cap V_{2,q}\) with the projected Veronese variety is precisely \(\pi_q(\Gamma)\).

The variety \(V_{PS}(Q, n) \subset \text{Hilb}_n(P^{n-1})\) is the closure of the set of polar simplices inside the set of apolar subschemes of length \(n\). The former set is irreducible, while the latter set is a closed variety defined by the condition that the generators of the ideal of the subscheme lie in \(q^\perp\). By Proposition 2.1, the map \(\Gamma \mapsto I_{\Gamma, 2} \subset q^\perp\) extends to all of \(V_{PS}(Q, n)\) as an injective morphism. □

We relate apolarity to polarity with respect to a quadric hypersurface. The classical notion of polarity is the composition of the linear map \(q^{-1}\) with apolarity: The polar to a point \([l] \in P(T_1)\) with respect to \(Q^{-1}\) is the hyperplane \(h_1 = P(q^{-1}(l^\perp)) \subset P(T_1)\), where

\[ (q^{-1}(l^\perp))^\perp = \{ l' \in T_1 | l'(q^{-1}(l)) = q^{-1}(l \cdot l') = 0 \}. \]

In particular, the polar hyperplane to \(l\) contains \(l\) if and only if \(q^{-1}(l^2) = 0\), i.e. the point \([l]\) lies on the hypersurface \(Q^{-1}\).

Let \(\Gamma \subset P(T_1)\) be a length \(n\) subscheme that contains \([l]\) and is apolar to \(Q\). The subscheme \(\Gamma' \subset \Gamma\) residual to \([l]\) is defined by the quotient \(I_{\Gamma'} = I_{\Gamma} : (l^\perp)\). Since \(\Gamma\) is non degenerate, \(\Gamma'\) spans a unique hyperplane. This hyperplane is defined by a unique linear form \(u' \in S_1\), and is characterized by the fact that \(u' \cdot u(q) = u'q(u) = 0\) for all \(u \in l^\perp\), so it is the hyperplane \(P(q(l^\perp))\). But

\[ l' \in q(l^\perp) \iff 0 = q^{-1}(l')l = q^{-1}(l \cdot l') = q^{-1}(l)l' \iff l' \in (q^{-1}(l))^\perp, \]

so \(P(q(l^\perp))\) is the polar hyperplane \(P(q^{-1}(l^\perp))\) to \([l]\) with respect to \(Q^{-1}\). Thus the subscheme \(\Gamma'\) residual to \([l]\) in \(\Gamma\) spans the polar hyperplane to \([l]\) with respect to \(Q^{-1}\).

Lemma 2.3. A component of an apolar subscheme has support on \(Q^{-1}\) if and only if this component is nonreduced.

Proof. If a component is a reduced point, the residual is contained in the polar hyperplane to this point, so by nondegeneracy the polar hyperplane cannot contain the point. If a component is nonreduced, the residual to the point supporting the component lies in the polar hyperplane to this point, so the point is on \(Q^{-1}\). □
Each component $\Gamma_0$ of an apolar subscheme to $q$ is apolar to a quadratic form $q_0$ defined on the span of $\Gamma_0$ and uniquely determined as a summand $q$. This is the content of the next proposition.

**Proposition 2.4.** Let $\Gamma = \Gamma_1 \cup \Gamma_2$ be an apolar subscheme of length $n$ to $q$ that decomposes into two disjoint subschemes $\Gamma_1$ and $\Gamma_2$ of length $n_1$ and $n_2$. Let $U_1 \subset T_1$ and $U_2 \subset T_1$ be subspaces such that $\Gamma_1$ spans $P(U_1)$. Then there is a unique decomposition $q = q_1 + q_2$ with $q_i \in (U_i)^\perp$.

Furthermore, subschemes $\Gamma_1 \subset P(U_1)$ and $\Gamma_2 \subset P(U_2)$ of length $n_1$ and $n_2$ are apolar to $q_1$ and $q_2$ respectively, if and only if $\Gamma_1 \cap \Gamma_2$ is apolar to $q$. 

**Proof.** Since $\Gamma$ is nondegenerate, $T_1 = U_1 \oplus U_2$. Let $U_1^\perp \subset S_1$ be the space of forms vanishing on $U_1$ via apolarity. Then $U_1^\perp$ are natural coordinates on $P(U_2)$ and likewise, $U_2^\perp$ are natural coordinates on $P(U_1)$. Let $I_1 \subset (U_2^\perp)^2$ be the quadratic forms generating the ideal of $\Gamma_1$ in $P(U_1)$, and likewise $I_2$ the quadratic forms generating the ideal of $\Gamma_2$ in $P(U_2)$. Then $I_1 \oplus I_2 \oplus (U_1^\perp) \cdot (U_2^\perp) \subset S_2$ is the space of quadratic forms in the ideal of $\Gamma$.

Consider the intersections, $q_2^\perp = q^\perp \cap (U_1^\perp)^2$ and $q_1^\perp = q^\perp \cap (U_2^\perp)^2$. Since $q$ is non degenerate, $q^\perp$ does not contain either of the subspaces $(U_1^\perp)^2$. Therefore $q_2^\perp$ is a codimension one subspace in $(U_1^\perp)^2$ and is apolar to a quadratic form $q_2 \in (U_2^\perp)^2$, unique up to scalar. Similarly, $q_1^\perp$ is apolar to a unique quadratic from $q_1 \in (U_1^\perp)^2$. The space of quadratic forms $q_1^\perp \oplus q_2^\perp \oplus (U_1^\perp) \cdot (U_2^\perp)$ is contained in $q^\perp$ and is apolar to the subspace $S(q_1,q_2) \subset T_2$. Therefore, there are unique nonzero coefficients $c_1$ and $c_2$ such that $q = c_1 q_1 + c_2 q_2$. Furthermore, each $\Gamma_1$ is apolar to $q_i$, $i = 1, 2$.

It remains only to show the last statement. Assume $\Gamma_1$ and $\Gamma_2$ are apolar to $q_1$ and $q_2$ respectively. Then $\Gamma_1 \cup \Gamma_2$ is non degenerate of length $n$. Let $I_1 \subset (U_2^\perp)^2$ be the generators of the ideal of $\Gamma_1$ and $I_2 \subset (U_1^\perp)^2$ be the generators of the ideal of $\Gamma_2$. Then the quadratic forms in 

$$I_1 \oplus I_2 \oplus (U_1^\perp) \cdot (U_2^\perp)$$

all lie in the ideal of $\Gamma_1 \cup \Gamma_2$. The dimension of this space of quadratic forms is 

$$\binom{n_1}{2} + \binom{n_2}{2} + n_1 \cdot n_2 = \binom{n}{2},$$

so they generate the ideal of $\Gamma_1 \cup \Gamma_2$. Since all these forms are apolar to $q = q_1 + q_2$, the subscheme $\Gamma_1 \cup \Gamma_2$ is apolar to $q$. \qed

**Remark 2.5.** By Proposition 2.4, the orbits of $SO(n,q)$ in $\text{VASP}(Q,n)$ are characterized by their components.

We shall return to the set of local apolar subschemes $V_p^{loc}(n)$ supported at a point $p \in Q^{-1}$ in section 5. Here we show that apolar subschemes of length $n$ to $q$ are all locally Gorenstein.

**Lemma 2.6.** Let $B$ be a local Artinian $C = B/m_B$-algebra of length $n$ and $\Phi : \text{Spec}B \rightarrow A^{n-1} \subset P^{n-1}$ the reembedding given by $C$-basis of $m_B$. The subscheme $\text{Im} \Phi$ is apolar to a full rank quadric if and only if $B$ is Gorenstein.
Proof. Let $\phi : A = \mathbb{C}[x_1, \ldots, x_{n-1}] \to B$ be the ring homomorphism corresponding to $\Phi$. Thus $\phi$ is defined by a linear $k$-isomorphism $\phi_1 = A_{\leq 1} = (1, x_1, \ldots, x_{n-1}) \to B$. Let $\pi : B \to (0 : m_B)$ be the projection onto the socle of $B$, let $\psi : (0 : m_B) \to \mathbb{C}$ be a linear form and consider the bilinear form

$$A \times A \overset{\phi \cdot \phi}{\longrightarrow} B \overset{\pi}{\longrightarrow} (0 : m_B) \overset{\psi}{\longrightarrow} \mathbb{C},$$

where the first map is the composition of $\phi$ with multiplication. This map extends to the tensor product $A \otimes A$, and the restriction then to the symmetric part $(A_{\leq 1})^2 \subset A_{\leq 1} \otimes A_{\leq 1}$ defines a linear form

$$\beta_\psi : (A_{\leq 1})^2 \to \mathbb{C}$$

and an associated quadratic form

$$q_\psi : A_{\leq 1} \to \mathbb{C}.$$

Clearly the kernel of $\beta_\psi$ generate an ideal in $A$ that is apolar to $q_\psi$. On the other hand, $B$ is Gorenstein if and only if the socle is 1-dimensional. So for the lemma, it suffices to prove that $q_\psi$ is non degenerate, i.e. has rank $n$, if and only if the linear form $\psi$ is an isomorphism.

But $q_\psi$ is degenerate if and only if the kernel of $\beta_\psi$ contains $x \cdot A_{\leq 1}$ for some nonzero element $x \in A_{\leq 1}$. Now, $\beta_\psi(x \cdot A_{\leq 1}) = 0$ if and only if $\phi(x) \cdot B \cap (0 : m_B) \subset \ker \psi$. Since $B$ is Artinian, $\phi(x) \cdot B \cap (0 : m_B)$ is a nonzero subspace of $(0 : m_B)$, so it suffices to consider elements $x$, which map to the socle. But then the kernel of $\beta_\psi$ contains $x \cdot A_{\leq 1}$ precisely when $x$ is in the kernel of $\psi$ and the lemma follows. \qed

Corollary 2.7. $VAPS(Q, n)$ is reducible for $n \geq 24$

Proof. Consider a general graded Artinian Gorenstein algebra $B$ of embedding dimension $e$ and socle in degree 3. The length of $B$ is $2e + 2$. By the Macaulay correspondence [Mac16], such algebras are in bijection with homogeneous forms, up to scalars, of degree 3 in $e$ variables, hence depends on $\binom{e-1+3}{3} = (e + 2)(e + 1)e/6 - 1$ variables. The family of smoothable algebras have dimension at most $e(2e + 2) - 1$ So for $e + 2 > 2 \cdot 6$ a general algebra $B$ cannot be smoothable, for trivial reason. In particular, $e = 11$ hence $n = 24$ is enough. \qed

We do not believe the bound $n \geq 24$ is sharp.

3. A rational parameterization

In this section we show that through a general point in $\mathbb{P}(T_{2,q})$ there is a unique $n$-secant $(n - 2)$-space to the projected Veronese variety $V_{2,q}$. Furthermore, we give a characterization of the points for which there are more than one, i.e. infinitely many $n$-secant $(n - 2)$-spaces to $V_{2,q}$.

If we choose basis $a$ for $T_1$ such that the symmetric matrix associated to $q$ is the identity matrix, then the eigenvectors of the symmetric matrix associated
to a general quadric $q'$ are distinct. Thus, the symmetric matrices associated to $q$ and $q'$ have a unique set of $n$ common 1-dimensional eigenspaces. Hodge & Pedoe [HP52, XIII.8,Theorem II] and Gantmacher [Gan59, Chapter XII, Theorem 3] found canonical forms for any pair of quadratic forms $q, q'$ as soon as one of them is nonsingular. Here we are concerned with the simplex formed by the set of common eigenspaces and give a geometric formulation and proof.

**Proposition 3.1.** Let $q, q' \in T_2$ be two general quadrics. Then there exists a unique $n$-simplex $\{L_1, \ldots, L_n\}$ polar to both $q$ and $q'$.

**Proof.** By the above, it suffices to show the relation between the collection of common eigenspaces of the associated symmetric matrices and the common simplex. So we assume that $q, q'$ are quadrics of rank $n$ and that

$$q = \sum_{i=1}^{n} l_i^2, \quad q' = \sum_{i=1}^{n} \lambda_i l_i^2,$$

where the $\lambda_i$ are pairwise distinct coefficients and $L_i = \{l_i = 0\}$, $i = 1, \ldots, n$. Let

$$q_i = \lambda_i q - q', \quad i = 1, \ldots, n.$$

Then the $q_i$ are precisely the quadratic forms of the pencil generated by $q$ and $q'$ that have rank less than $n$. The rank of $q_i$ is exactly $n - 1$ since $\lambda_i \neq \lambda_j$ for $i \neq j$, so $q_i \in (U_i)^2$ for a unique rank $n - 1$ subspace $U_i \subset T_1$. The intersection $\cap_{i \neq j} U_i$ is the 1-dimensional subspace generated by the nonzero linear form $l_j$. These forms are therefore determined uniquely by the pencil generated by $q$ and $q'$. □

A precise condition for generality in the proposition is given by rank:

**Lemma 3.2.** A pencil of quadratic forms in $n$ variables have a unique common apolar subscheme of length $n$ if and only if every quadric in the pencil have rank at least $n - 1$ and some, hence the general quadric has rank $n$. Furthermore the unique apolar subscheme is curvilinear, i.e. embeddable in a smooth curve.

**Proof.** Let

$$(q' + \lambda q)_{\lambda \in \mathbb{A}_k^1}$$

be a pencil with discriminant $\Delta \subset \mathbb{A}_k^1$, a scheme of length $n$. Consider the incidence

$$\{(D, \lambda)|D(q' + \lambda q) = 0\} \subset \mathbb{P}(T_1) \times \mathbb{A}_k^1$$

with projections $p_T$ and $p_C$. Clearly the fibers of each projection are all linear. Now as in the proof of the proposition, a general length $n$ subscheme of $p_T(\mathbb{P}^1_c(\Delta))$ is a common apolar subscheme to the pencil of quadratic forms. Therefore, the common apolar subscheme is unique if and only if $p_T(\mathbb{P}^1_c(\Delta))$ is finite, i.e. the corank of any quadric in $L$ is at most 1. In this case both projections restricted to the incidence are isomorphisms onto their images. In particular the apolar subscheme is isomorphic to $\Delta$, so it is curvilinear. □
Remark 3.3. The ideal of the curvilinear image $\Gamma$ of the map

$$\text{Spec } \mathbb{C}[t]/(t^n) \to \mathbb{P}^{n-1}$$

$$t \mapsto (1 : t : t^2 : \ldots : t^{n-1}),$$

is generated by the $2 \times 2$ minors of

$$\begin{pmatrix} x_1 & x_2 & \ldots & x_{n-1} & x_n \\ x_2 & x_3 & \ldots & x_n & 0 \end{pmatrix},$$

so the $\Gamma$ is apolar to the maximal rank quadric

$$\sum_{k=1}^{n} y_k y_{n+1-k}.$$  

This remark generalizes to a partial converse of Lemma 3.2.

Lemma 3.4. Any curvilinear nondegenerate zero-dimensional subscheme $\Gamma \subset \mathbb{P}^{n-1}$ of length $n$ is apolar to a quadric $Q \subset \mathbb{P}^{n-1}$ of maximal rank.

Proof. Let $\Gamma$ be a nondegenerate curvilinear subscheme with $r$ components of length $n_1, \ldots, n_r$ such that $n_1 + \ldots + n_r = n$. Then $\Gamma$ is projectively equivalent to $\Gamma' = \Gamma_1 \cup \ldots \cup \Gamma_r$, where $\Gamma_i$ is the image of

$$\text{Spec } \mathbb{C}[t]/(t^{n_i}) \to \mathbb{P}(\mathbb{C}^{n_1} \oplus \ldots \oplus \mathbb{C}^{n_r})$$

$$t \mapsto (1 : t : t^2 : \ldots : t^{n_i-1}),$$

where the nonzero coordinates in the image are $x_{i,1}, \ldots, x_{i,n_i}$. The ideal of $\Gamma'$ is generated by the $2 \times 2$ minors of the $r$ matrices

$$\begin{pmatrix} x_{(1,1)} & \ldots & x_{(1,n_i-1)} & x_{(1,n_i)} \\ x_{(1,2)} & \ldots & x_{(1,n_i)} & 0 \end{pmatrix} \ldots \begin{pmatrix} x_{(r,1)} & \ldots & x_{(r,n_i-1)} & x_{(r,n_i)} \\ x_{(r,2)} & \ldots & x_{(r,n_i)} & 0 \end{pmatrix},$$

and the products

$$x_{(i,k)}x_{(j,k)} \quad \text{for} \quad 1 \leq i < j \leq r, 1 \leq k_i \leq n_i, 1 \leq k_j \leq n_j.$$  

So $\Gamma'$ is apolar to the maximal rank quadric

$$\sum_{i=1}^{r} \sum_{k=1}^{n_i} y_{(i,k)} y_{(i,n_i+1-k)}.$$  

□

More important to us will be that rank $n$ quadrics have apolar subschemes of length $n$ that are not curvilinear (when $n > 3$).

Remark 3.5. Consider the rank $n$ quadric

$$q = 2y_1y_n + y_2^2 + \ldots + y_{n-1}^2.$$  

The subscheme $\Gamma_q \subset \mathbb{P}^{n-1}$ defined by

$$(x_1^2, x_1x_2, x_2^2 - x_1x_n, x_1x_3, \ldots, x_{n-1}^2 - x_1x_n),$$

has degree $n$ and is apolar to $q$, but it is clearly not curvilinear when $n > 3$. It contains the tangency locus of the quadric $q^{-1} = \frac{1}{2}x_1x_n + \frac{1}{4}x_2^2 + \ldots + \frac{1}{n}x_{n-1}^2$.  

Documenta Mathematica 18 (2013) 469–505
0) at the point $[0 : 0 : \ldots : 1]$. The tangency locus has length $n - 1$ and is defined by
\[(x_1, (x_2^2 - x_1x_n, x_2x_3, \ldots, x_{n-1}^2 - x_1x_n)).\]
The subscheme $\Gamma_p$ is itself not contained in the tangent hyperplane $\{x_1 = 0\}$, but it is the unique apolar subscheme to $q$ that contains the first order neighborhood of $[0 : 0 : \ldots : 1]$ on $\{q^{-1} = 0\}$. It will be the focus of our attention in Section 5.

It follows immediately from Proposition 3.1 that there is a rational and dominant map
\[\gamma : P(T_{2,q}) \to VPS(Q,n) \subset G(n-1,T_{2,q})\]
whose general fiber is a $n$-secant $(n-2)$-space to the projected Veronese variety $V_{2,q}$. In the next section we find equations for this map.

4. The Mukai form

Mukai introduced in [Muk92] a trilinear form in his approach to varieties of sums of powers of conics in particular, and to forms of even degree in general (see also [Dol12, Sections 1.4 and 2.1.3]). In this section we show how this form naturally gives equations for the map $\gamma$ and for the universal family of polar simplices. The main result of this section, Proposition 4.2, gives the equations for the common apolar subscheme of length $n$ of a pencil of quadrics in $n$ variables, whenever this subscheme is unique, cf. Lemma 3.2.

Both the quadratic form $q \in T_2$ and the inverse $q^{-1} \in S_2$ play a crucial role in the definition of the Mukai form. Recall that the form $q$ defines an invertible linear map $q : S_1 \to T_1$, and $q^{-1}$ defines the inverse map: $q^{-1} : T_1 \to S_1$. In coordinates, if $q = (a_1 y_1^2 + \ldots + a_n y_n^2)$, then $q^{-1} = (\frac{1}{4a_1} x_1^2 + \ldots + \frac{1}{4a_n} x_n^2)$.

We will arrive at Mukai’s form from
\[\tau \in \text{Hom}(\wedge^2 S_1 \otimes T_2 \otimes T_2 \otimes S_2, C)\]
defined by
\[z_1 \wedge z_2 \otimes q_1 \otimes q_2 \otimes \alpha \mapsto (z_1(q_1))z_2(q_2) - z_2(q_1)z_1(q_2))(\alpha)\]
where $f(g)$, as above, means $f$ viewed as differential operator applied to $g$. Interpreting $\omega = z_1 \wedge z_2 \in \wedge^2 S_1 \subset \text{Hom}(T_1, S_1)$, $q_j \in T_2 \subset \text{Hom}(S_1, T_1)$ and $\alpha \in S_2 \subset \text{Hom}(T_1, S_1)$ the expression
\[(\omega \otimes q_1 \otimes q_2 \otimes \alpha) \mapsto \frac{1}{2} \text{trace} \ (\alpha \circ q_2 \circ \omega \circ q_1 - \alpha \circ q_1 \circ \omega \circ q_2)\]
\[= \frac{1}{2} \text{trace} \ (\omega \circ q_1 \circ \alpha \circ q_2 - \alpha \circ q_1 \circ \omega \circ q_2)\]
gives an alternative description of $\tau$. In fact $f(g) = \frac{1}{2} \text{(trace } f \circ g \text{)}$ holds for $f \otimes g \in S_2 \otimes T_2 \subset \text{Hom}(T_1, S_1) \otimes \text{Hom}(S_1, T_1)$ and $\text{trace} ((\alpha \circ q_2) \circ (\omega \circ q_1)) = \text{trace} ((\omega \circ q_1) \circ (\alpha \circ q_2))$. We now substitute $\alpha = q^{-1}$. Then $\frac{1}{2} \text{trace} \ (\omega \circ q_1 \circ q^{-1} \circ q_2 - q^{-1} \circ q_1 \circ \omega \circ q_2) = 0$ for $q_1 = q$, and, since the first expression for $\tau$ is
alternating on $T_2 \otimes T_2$, we have $\frac{1}{2} \text{trace } (\omega \circ q_1 \circ q^{-1} \circ q_2 - q^{-1} \circ q_1 \circ \omega \circ q_2) = 0$ for $q_2 = q$ as well. Thus $\tau$ induces a well defined trilinear form

$$
\tau_q \in \text{Hom}(\wedge^2 S_1 \otimes T_{2,q} \otimes T_{2,q}, \mathbb{C})
$$
on the quotient space $T_{2,q} = T_2 / \langle q \rangle$.

Since $T_{2,q}^* = q^* \subset S_2 = T_2^*$ and

$$
\text{Hom}(\wedge^2 S_1 \otimes T_{2,q} \otimes T_{2,q}, \mathbb{C}) \cong \text{Hom}(T_{2,q}, \text{Hom}(\wedge^2 S_1, q^*))
$$
we have a second interpretation of $\tau_q$. With this interpretation, the image of $\tau_q(q_1) \in \text{Hom}(\wedge^2 S_1, q^*) \subset \text{Hom}(\wedge^2 S_1, S_2)$ is defined by

$$
\omega \mapsto [\omega \circ q_1 \circ q^{-1} - q^{-1} \circ q_1 \circ \omega] \in q^* \subset S_2 \subset \text{Hom}(T_1, S_1).
$$
The form $\tau$ is alternating on $T_2 \otimes T_2$, so $\tau(\omega, q', q'^{-1}) = 0$ for every $\omega \in \wedge^2 S_1$. Therefore

$$
\tau_q(q')(\wedge^2 S_1) \subset (q')^\perp.
$$
If $Q'$ is the quadric $\{q' = 0\} \subset \mathbb{P}(S_1)$, we may therefore conclude:

**Lemma 4.1.** Any quadratic form in $\tau_q(q')(\wedge^2 S_1)$ is apolar to both $Q$ and $Q'$:

$$
\tau_q(q')(\wedge^2 S_1) \subset q^\perp \cap (q')^\perp.
$$

□

Notice that the linear space of quadratic forms $\tau_q(q')(\wedge^2 S_1)$ is not all of $q^\perp \cap (q')^\perp$. It is a special subspace of the intersection. Since $\tau_q(q) = 0$, we have $\tau_q(q') = \tau_q(q' + \lambda q)$ for any $\lambda$, so the space $\tau_q(q')(\wedge^2 S_1)$ of quadratic forms depends only on the pencil $\langle q, q' \rangle$.

If the pencil of quadratic forms $\langle q, q' \rangle \subset T_2$ contains no forms of corank at least 2, then, by Lemma 3.2, there is a unique common apolar subscheme $\Gamma_{q'}$ of length $n$ to $q$ and $q'$. The significance of the form $\tau_q$ is

**Proposition 4.2.** Let $q' \in T_{2,q}$. Then the linear map

$$
\tau_q(q') : \wedge^2 S \rightarrow q^\perp
$$
is injective if and only if $q$ and $q'$ have a unique common apolar subscheme of length $n$. Furthermore, in this case the image generates the ideal in $S$ of this subscheme.

**Proof.** Our argument depends on several lemmas, in which we study $\text{Im } \tau_q(q') \subset S_2$ by considering the symmetric matrices associated to these quadratic forms with respect to a suitable basis. Thus, we choose coordinates such that $q = \frac{1}{2}(y_1^2 + y_2^2 + \ldots + y_n^2)$ and hence $q^{-1} = \frac{1}{2}(x_1^2 + x_2^2 + \ldots + x_n^2)$. The symmetric matrices of these quadratic forms with respect to the coordinate basis of $T_1$ and $S_1$ are both the identity matrix. We denote by $A$ the symmetric matrix of $q'$, i.e. $q' = \frac{1}{2}(y_1, \ldots, y_n)A(y_1, \ldots, y_n)^t$. For a form $\omega \in \wedge^2 S_1$ there is similarly an associated skew symmetric matrix $\Lambda_\omega$. For a form $l \in T_1$ we denote by $v_l$ the column vector of its coordinates. The quadratic forms in the image $\tau_q(q')$ are the forms associated to the symmetric bilinear forms

$$
\{\omega \circ q' \circ q^{-1} - q^{-1} \circ q' \circ \omega | \omega \in \wedge^2 S_1\}.
$$

**Documenta Mathematica 18 (2013) 469–505**
so their associated symmetric matrices are

\[ \{ \lambda \omega A - A \lambda \omega | \omega \in \wedge^2 S_1 \} \]

**Lemma 4.3.** Let \([l] \in P(T_1)\), then every quadric in \(\tau_q(q')(\wedge^2 S) \subset q^+\) vanishes at the point \([l]\) if and only if there is a quadric \(q_\lambda = q' + \lambda q\) for some \(\lambda \in \mathbb{C}\), such that \(l\) lies in the kernel of the linear transformation \(q_\lambda \circ q^{-1} : T_1 \to T_1\).

Equivalently, in terms of matrices: If \(v_l\) is the column coordinate vector of \(l\), then \(v_l^t (\lambda \omega A - A \lambda \omega) v_l = 0\) for every \(\omega \in \wedge^2 S_1\) if and only if \(v_l\) is an eigenvector for the matrix \(A\).

**Proof.** Note first that the matrix of the linear transformation \(q_\lambda \circ q^{-1}\), with respect to the coordinate basis of \(T_1\), is simply \(A + \lambda I\). Hence, the two parts of the lemma are equivalent.

In the matrix notation, if \(v_l\) is an eigenvector for \(A\) with eigenvalue \(\lambda\), then

\[
v_l^t (\lambda \omega A - A \lambda \omega) v_l = v_l^t \lambda \omega A v_l - v_l^t A \lambda \omega v_l = v_l^t \lambda \omega v_l - \lambda v_l^t \lambda \omega v_l = 0,
\]

so the if part follows.

Conversely, assume that

\[
v_l^t (\lambda \omega A - A \lambda \omega) v_l = 0
\]

for every skew symmetric \(n \times n\) matrix \(\lambda \omega\). Again

\[
v_l^t (\lambda \omega A - A \lambda \omega) v_l = v_l^t \lambda \omega A v_l - v_l^t \lambda \omega A v_l,
\]

and since \(A\) is symmetric and \(\lambda \omega\) is skewsymmetric, \((v_l^t \lambda \omega A v_l)^t = -v_l^t A \lambda \omega v_l\), so we deduce that

\[
v_l^t \lambda \omega A v_l = 0.
\]

But \(v_l^t \lambda \omega u = 0\) for every skew symmetric matrix \(\lambda \omega\) only if \(u\) is proportional to \(v_l\), so we conclude that \(A(v_l) = \lambda v_l\) for some \(\lambda\).

**Remark 4.4.** A point \(l \in T_1\) lies in the kernel of \(q_\lambda \circ q^{-1}\) if and only if \(q^{-1}(l)\) lies in the kernel of \(q_\lambda : S_1 \to T_1\). Equivalently, \(\{q_\lambda = 0\} \subset P(S_1)\) is a singular quadric and \([q^{-1}(l)] \in P(S_1)\) lies in its singular locus.

**Corollary 4.5.** \(\tau_q(q')\) is injective only if \(\langle q, q' \rangle\) contains no quadratic form of rank less than \(n - 1\).

**Proof.** If the quadratic form \(q_\lambda = q' + \lambda q\) has rank less than \(n - 1\), then there are independent forms \(l, l' \in T_1\) such that \((q^{-1}(l), q^{-1}(l'))\) is contained in the kernel of \(q_\lambda : S_1 \to T_1\). In particular, viewed as differential operators applied to \(q_\lambda\),

\[
q^{-1}(l)(q_\lambda) = q^{-1}(l')(q_\lambda) = 0 \in T_1.
\]

Let

\[
\omega = q^{-1}(l) \wedge q^{-1}(l') \in \wedge^2 S_1 \subset \text{Hom}(T_1, S_1).
\]

Then

\[
\omega \otimes q_\lambda \otimes q_2 \otimes q^{-1} \to [q^{-1}(l)(q_\lambda) \cdot q^{-1}(l')(q_2) - q^{-1}(l')(q_\lambda) \cdot q^{-1}(l)(q_2)](q^{-1}) = 0
\]

for every \(q_2 \in T_2\), so \(\tau_q(q')(\omega) = 0\) and \(\tau_q(q')\) is not injective. \(\square\)
To complete the proof of Proposition 4.2, we assume that $q$ and $q'$ have a unique common apolar subscheme $\Gamma$ of length $n$, i.e. by Lemma 3.2, no quadratic form in $\langle q, q' \rangle$ has rank less than $n - 1$. We want to show that $\tau_q(q')$ is injective and that the image generates the ideal of $\Gamma$.

Let $\Gamma = \Gamma_1 \cup \ldots \cup \Gamma_r$ be a decomposition of $\Gamma$ into its connected components. Then each $\Gamma_i$ is a finite local curvilinear scheme. Let $n_i$ be the length of $\Gamma_i$. By Proposition 2.4, there is a decomposition $T_1 = \oplus_i U_i$ such that each $\Gamma_i \subset P(U_i)$. Furthermore $U_i$ has dimension $n_i$ and $q$ and $q'$ have unique decompositions $q = q_1 + \ldots + q_r$ and $q' = q'_1 + \ldots + q'_r$ with $q_i, q'_i \in (U_i)^2 \subset T_2$. Denote by $U'_i = \oplus_{j \neq i} U_j$, and let $(U'_i)' \subset$ be the orthogonal subspace of linear forms in $S_1$. Then

$$\sum_i U_i \cdot (U'_i)' \subset S_2$$

generate the ideal of $U_i P(U_i) \subset P(T_1)$.

The linear forms $q^{-1}(U_i) \subset S_1$ are natural coordinates on $P(U_i)$. Denote by $I_{\Gamma_i, 2}$ the quadratic forms in these coordinates in the ideal of $\Gamma_i$. Then $I_{\Gamma_i, 2} \subset (q^{-1}(U_i))^2 \subset S_2$ and the space of quadratic forms in the ideal of $\Gamma$ is

$$I_{\Gamma, 2} = \sum I_{\Gamma_i, 2} + \sum_i U_i \cdot (U'_i)' \subset S_2.$$ 

We have

**Claim 4.6.**

$$\text{Im } \tau_q(q') \supset \sum_i I_{\Gamma_i, 2} + \sum_i U_i \cdot (U'_i)'.$$ 

If the claim holds, $\tau_q(q')$ is injective, since $\dim \wedge^2 S_1 = \dim I_{\Gamma, 2} = \binom{n}{2}$, so the equality $\text{Im } \tau_q(q') = I_{\Gamma, 2}$ holds and the proof of Proposition 4.2 is complete.

We use matrices to prove the claim. To interpret the decomposition of $q$ and $q'$ in terms of matrices, we choose a basis for each $U_i$ such that the symmetric matrix associated to each $q_i$ is the $n_i \times n_i$ identity matrix. Let $A_i$ be the symmetric $n_i \times n_i$ matrix associated to $q'_i$. The union of the bases for the $U_i$ form a basis for $T_1$ with respect to which the symmetric matrix $A$ of $q'$ has $r$ diagonal blocks $A_i$ and zeros elsewhere.

The matrices $A_i$ each have a unique eigenvalue $\lambda_i$, and these eigenvalues are pairwise distinct. Furthermore, each $A_i$ has a 1-dimensional eigenspace, so their Jordan form has a unique Jordan block, and we may write $A_i = \lambda_i I_{n_i} + B_i$ with $B_i$ a nilpotent symmetric matrix. (See ([DZ04, Theorem 2.3]) for a nice normal form for the matrices $B_i$.)

By extending each $A_i$ with zeros to $n \times n$ matrices, we may write $A = \sum A_i$. The decomposition $T_1 = \oplus_i U_i$ is then defined by $U_i = \ker(\lambda_i I - A)^{n_i} \subset T_1$.

Denote by $U'_i = \oplus_{j \neq i} U_j$. Then $P(U_i)$ and $P(U'_i)$ have complementary dimension in $P(T_1)$. We shall use the techniques applied by Gantmacher in the analysis of commuting matrices ([Gan59, Chapter VIII]) to show

**Lemma 4.7.** Let $A$ be the symmetric matrix of the quadratic form $q' \in T_2, q$ as above. Let $T_1 = U_i \oplus U'_i$ be the decomposition associated to the eigenvalue $\lambda_i$. 

\[
\text{Im } \tau_q(q') \supset \sum_i I_{\Gamma_i, 2} + \sum_i U_i \cdot (U'_i)'.
\]
Set $A$ a symmetric matrix and let $\Lambda_{\lambda, \mu}$ an $d, j > d$.

Then \(U^\perp \cdot (U')^\perp \subset \text{Im} \tau_q(q') \subset S_2\).

**Proof.** Set $d = n_i$ and $\lambda = \lambda_i$ and choose coordinates such that $U_\lambda = \langle y_1, \ldots, y_d \rangle$ and $U'_\lambda = \langle y_{d+1}, \ldots, y_n \rangle$. Then $(U')^\perp = \langle x_1, \ldots, x_d \rangle$ and $(U^\perp)^\perp = \langle x_{d+1}, \ldots, x_n \rangle$.

Consider the matrix $B$ of the quadratic form $\tau_q(q')(x_i \wedge x_j)$ with $i \leq d$ and $j > d$.

The skew symmetric matrix $\Lambda_{ij}$ of $x_i \wedge x_j$ has $(ij)$-th entry 1, consequently $(ji)$-th entry $-1$, and 0 elsewhere, and

\[ B = \Lambda_{ij} A - AA_{ij} . \]

The nonzero entries in $\Lambda_{ij} A$ are in positions $(i, k)$ with $k > d$ and $(j, k)$ with $k \leq d$, while the nonzero entries in $A \Lambda_{ij}$ are in positions $(k, i)$ with $k > d$ and $(k, j)$ with $k \leq d$. Therefore the quadratic form $\tau_q(q')(x_i \wedge x_j)$ lies in the space $\langle x_a x_b \rangle_{a \leq d < b} = (U')^\perp \cdot (U^\perp)^\perp$.

A linear relation between these quadratic forms would correspond to a skew symmetric matrix $A$ with nonzero entries only in the rectangular block $(ij)$, $i \leq d, j > d$, such that $AA - AA = 0$. Write $A$ as a sum $A = A_\lambda + A_{\mu_1} + \ldots + A_{\mu_n}$ where the $\mu_i$ are the eigenvalues of $A$ distinct from $\lambda$. Let $\Lambda$ be a skew symmetric matrix and let $\Lambda_{\lambda, \mu_i}$ be the rectangular submatrix with rows equal to the nonzero rows of $A_\lambda$ and columns equal to the nonzero columns of $A_{\mu_i}$.

Then the corresponding submatrix

\[(\Lambda A - AA)_{\lambda, \mu_i} = \Lambda_{\lambda, \mu_i} A_{\mu_i} - A_\lambda \Lambda_{\lambda, \mu_i} . \]

So $\Lambda A - AA = 0$ only if $\Lambda_{\lambda, \mu_i} A_{\mu_i} - A_\lambda \Lambda_{\lambda, \mu_i} = 0$ for each $\mu_i$.

Let $\mu$ be one of the $\mu_i$, for simplicity $U_\mu = \langle y_{d+1}, \ldots, y_{d+e} \rangle$. Let $I_d$ be the diagonal matrix with 1 in the $d$ first entries and 0 elsewhere, and let $I_e$ be the diagonal matrix with 1 in the entries $d + 1, \ldots, d + e$ and 0 elsewhere. Then the special summand $A_\lambda$ of $A$ can be written as a sum $A_\lambda = M_d + B_d$ where $B_d$ is nilpotent of order $d$. Likewise, $A_{\mu} = \mu I_e + B_e$ where $B_e$ is nilpotent of order $e$. So we may write $A = M_d + B_d + \mu I_e + B_e + A'$, where $A' = A - A_\lambda - A_{\mu}$.

But then $(\Lambda A - AA)_{\lambda, \mu} = 0$ only if

\[ A_{\lambda, \mu} A_{\mu} - A_\lambda A_{\lambda, \mu} = 0 , \]

i.e. when

\[ A_{\lambda, \mu}(\mu I_e + B_e) - (\lambda I_d + B_d) A_{\lambda, \mu} = 0 . \]

This is equivalent to

\[(\lambda - \mu) A_{\lambda, \mu} = A_{\lambda, \mu} B_e - B_d A_{\lambda, \mu} . \]

Multiplying both sides by $(\lambda - \mu)$ and substituting on the right hand side $(\lambda - \mu) A_{\lambda, \mu}$ with $A_{\lambda, \mu} B_e - B_d A_{\lambda, \mu}$ we get

\[ (\lambda - \mu)^2 A_{\lambda, \mu} = (A_{\lambda, \mu} B_e - B_d A_{\lambda, \mu}) B_e - B_d (A_{\lambda, \mu} B_e - B_d A_{\lambda, \mu}) \]

\[ = (A_{\lambda, \mu} B_e)^2 - 2 B_d A_{\lambda, \mu} B_e + (B_d)^2 A_{\lambda, \mu} . \]

Iterating $m = d + e - 1$ times we get
Let $\Lambda$ be a skew symmetric matrix. Hence $\Lambda$ has rank $\leq d, j > d$ are linearly independent. The corresponding quadratic forms are linearly independent in the space $\langle x_1, \ldots, x_d \rangle \times \langle x_{d+1}, \ldots, x_n \rangle$. Since the dimensions coincide, the quadratic forms span this space, and the lemma follows. 

Next, we consider the case when the symmetric matrix $A$ has only one eigenvalue and up to scalars only one nonzero eigenvector. Hence $q$ has rank $n - 1$ i.e. that the eigenvalue is 0. Then $A$ is nilpotent, and since $A$ is a one-dimensional eigenvector space, $A^n = 0$ and $A^i \neq 0$ for any $i < n$.

**Lemma 4.8.** Let $q' \in T_{2,q}$ be a quadratic form whose associated $n \times n$ matrix $A$ is symmetric, nilpotent and has rank $n - 1$. Then the ideal generated by the quadratic forms $\tau_q(q') \subset q^c$ is the ideal of the unique common apolar subscheme $\Gamma$ of length $n$ of $q$ and $q'$. Moreover $\Gamma$ is a local curve linear subscheme.

**Proof.** Let $A$ be a skew symmetric $n \times n$ matrix and think of $A$ and $\Lambda$ as the matrices of linear endomorphisms of a $n$-dimensional vector space $V$. Then we may choose a basis $v_1, \ldots, v_n \in V$ such that $Av_1 = 0$ and $Av_i = v_{i-1}$ for $i = 2, \ldots, n$. Let $\rho : \text{Spec}(\mathbb{C}[t]/t^n) \to \mathbf{P}(V) : t \mapsto [v_1 + tv_2 + \ldots + t^{n-1}v_n]$ and set $\Gamma = \text{Im} \rho$. Then $I_{\Gamma}$ is generated by $\binom{n}{2}$ quadratic forms. We shall show that the symmetric matrices of these forms coincide with the matrices $\Lambda A - A$ as $\Lambda$ varies. We evaluate the quadratic form associated to $\Lambda A - A$ on the vector $v = v_1 + tv_2 + \ldots + t^{n-1}v_n$:

$$v^t(\Lambda A - A)v = v^t\Lambda A v - v^t A v.$$ 

But

$$v^t\Lambda A v = (v_1 + tv_2 + \ldots + t^{n-1}v_n)^t \Lambda (v_1 + tv_2 + \ldots + t^{n-1}v_n)$$

$$= (v_1 + tv_2 + \ldots + t^{n-1}v_n)^t \Lambda (v_1 + \ldots + t^{n-1}v_{n-1})$$

$$= (v_1 + \ldots + t^{n-2}v_{n-1})^t \Lambda (v_1 + \ldots + t^{n-2}v_{n-1}) t$$

$$+ t^n v_n^t \Lambda (v_1 + \ldots + t^{n-2}v_{n-1})$$

$$= 0$$

since $\Lambda$ is skew symmetric and $t^n = 0$. Therefore the quadratic forms with matrices $\Lambda A - A$ are in the ideal of $\Gamma$. They are independent and therefore
generate the ideal unless AA - ΛΛ = 0 for some nontrivial Λ. But then Λ and A commute, hence have common eigenvectors. Λ is nontrivial and skew symmetric so it has at least 2 independent eigenvectors, while A has only one, so this is impossible. Clearly, Γ is curvilinear, and any non degenerate local curvilinear subscheme of length n in P(V) is projectively equivalent to it, so the lemma follows. □

To complete the proof of the claim 4.6 and the proof of Proposition 4.2, we consider the common apolar subscheme Γ = Γ₁ ∪ ... ∪ Γᵣ to q and q', and the corresponding decompositions q = ∑ qᵢ and q' = ∑ q'ᵢ as above. By Lemma 4.7,

\[ \sum_i U_i ^⊥ \cdot (U_i ') ^⊥ \subset \text{Im } τ(q). \]

Furthermore, applying Lemma 4.8 to each component qᵢ and qᵢ', the image of τᵢ(qᵢ) in (q⁻¹(Uᵢ))² is I₊,i. But τᵢ(qᵢ') is the restriction of τᵢ(q') to ∧²(q⁻¹(Uᵢ)), so

\[ I₊,i \subset \text{Im } τ(q') \quad i = 1, ..., r \]

and the claim and Proposition 4.2 follows. □

By Lemma 4.3, the quadratic forms in Im τᵢ(q') vanish in every point on any common apolar subscheme of length n to q and q'. Combined with Proposition 4.2 it may be reasonable to guess that Im τᵢ(q') is precisely the quadratic forms in the intersection of the ideals of these common apolar subschemes. We do not have a clear answer and leave this as an open question.

We are now ready to analyze our main object VPS(Q,n) in its embedding in G(n - 1, T₂,q), i.e. as the image of the rational map

\[ γ : P(T₂,q) \rightarrow G(n - 1, T₂,q). \]

We identify the restriction of the Plücker divisor to VPS(Q,n).

Let h ⊂ P(T₁) be a hyperplane, and denote by Hₕ ⊂ VSQ(Q,n) the set

\[ Hₕ = \{ [Γ] \in VSQ(Q,n)|Γ \cap h \neq 0 \}. \]

Lemma 4.9. Hₕ is the restriction to VPS(Q,n) of a Plücker divisor on G(n - 1, T₂,q).

Proof. The hyperplane h ⊂ P(T₁) is defined by some l ∈ S₁. Let V(l) = {q' ∈ T₂|l(q') = 0}, then V(l) = l ∩ S₁ = {l' | l' ∈ S₁} ⊂ S₂.

For any nondegenerate subscheme Γ ⊂ P(T₁) of length n, the ideal Iₚ ⊂ S contains a reducible quadric l₁.l₂ only if Γ intersects both hyperplanes {l₁ = 0} and {l₂ = 0}. On the other hand the subspace of quadrics I₊,₂ ⊂ S₂ has codimension n, which coincides with the dimension of l ∩ S₁. Therefore

\[ I₊,₂ ∩ l ∩ S₁ \neq 0 \subset S₂ \] if and only if \( (I₊,₂) ^⊥ \cap V(l) \neq 0 \subset T₂. \]

Notice that P((I₊,₂) ^⊥) equals the span (Γ) ⊂ P(T₂) of Γ in the Veronese embedding.

For the lemma we now consider apolar subschemes to q and the projection from P(T₂) to P(T₂,q). Since q has maximal rank, l(q) ≠ 0, i.e. q ∉ V(l). Thus
The orthogonal space of quadratic forms in $S_T$ and intersect $q_P$: 1]

We choose coordinates such that $P$ irreducible and therefore coincides with $VPS_Q$ The quadric $Q$ is spanned by \[ \langle x_1^2, x_1x_2, x_2^2, x_1x_3, x_2x_3, \ldots, x_{n-1}^2, x_n \rangle \]

n intersection of the projected Veronese variety $V$ and consider the apolar subscheme $\Gamma$ of length $n$. But the set of $(n - 2)$-dimensional subspaces in $P(T_2,q)$ that intersect a linear space of codimension $n$ form a Plücker divisor, so the lemma follows. □

In the next section we use the special Plücker divisors $H_h$ of this lemma to give a local affine description of $VPS(Q,n)$, or better, the variety $VAPS(Q,n)$ of all apolar subschemes of length $n$.

5. An open affine subvariety

We use a standard basis approach to compute an open affine subvariety of $VAPS(Q,n)$, the variety of all apolar subschemes of length $n$ to $Q$. Of course this will include our primary object of interest, namely $VPS(Q,n)$. For small $n$ there will be no difference, but for larger $n$ we have already seen that they do not coincide. The distinction between the two will eventually be the main concern in our analysis. The computations in this section extensively use Macaulay2 [GS]. In particular when we show, by direct computation, that $VAPS(Q,6)$ is irreducible and therefore coincides with $VPS(Q,6)$ (Corollary 5.16).

We choose coordinates such that $Q = \{ q = 2y_1y_n + y_2^2 + \ldots + y_{n-1}^2 = 0 \}$, and consider the apolar subscheme $\Gamma_p$ to $q$ defined by

\[ \langle x_1^2, x_1x_2, x_2^2 - x_1x_n, x_1x_3, x_2x_3, \ldots, x_{n-1}^2 - x_1x_n \rangle. \]

It is of length $n$ and corresponds in the setting of the previous section to the intersection of the projected Veronese variety $V_2,q$ with the tangent space $T_p$ to $v_2(Q^{-1}) \subset P(T_2,q)$ at the point $v_2(p) = [y_2] \in P(T_2,q)$, where $p = [y_n] = [0 : \ldots : 1] \in P(T_1)$. The tangent space to the Veronese variety $V_2 \subset P(T_2)$ at $[y_2]$ is spanned by

\[ \langle y_1y_n, y_2y_n, \ldots, y_{n-1}y_n, y_{n-1} \rangle. \]

The quadric $Q^{-1}$ is defined by $\frac{1}{2}x_1x_n + \frac{1}{4}(x_2^2 + \ldots + x_{n-1}^2)$. Its tangent space in $P(T_1)$ at $[y_n]$ is defined by $x_1$, so its tangent space in $P(T_2)$ at $[y_2]$ is defined by $x_1$ inside the tangent space to the Veronese variety. Therefore, the tangent space $T_p$ to $v_2(Q^{-1})$ is spanned by

\[ \langle y_2y_n, \ldots, y_{n-1}y_n, y_{n-1} \rangle. \]

The orthogonal space of quadratic forms in $S_2$ is spanned by

\[ \langle x_1^2, x_1x_2, x_2^2, x_1x_3, x_2x_3, \ldots, x_{n-1}^2, x_1x_n \rangle \]

and intersect $q^{-1}$ precisely in the ideal of $\Gamma_p$ given above.
We therefore consider the open subvariety $V \in \text{Aff}(\mathbb{P}^n)$ for $\Gamma$ the tangent hyperplane to any apolar scheme $\Gamma$ that does not intersect the hyperplane $\{x_n = 0\}$. In fact, if the initial ideal of $\Gamma$ contains $x_i x_n$, then $x_n$ divides a quadratic form in the ideal of $\Gamma$. But if $\Gamma$ does not intersect $\{x_n = 0\}$, then $\Gamma$ would be degenerate.

We therefore consider the open subvariety $V_{\text{aff}}(n)$ containing $[\Gamma_p]$ in $V_{\text{APS}}(Q, n)$, parametrizing apolar subschemes $\Gamma$ of length $n$ with support in $D(x_n)$. This is the complement of the divisor $H_n$ defined by $h = [x_n = 0]$, the tangent hyperplane to $Q^{-1}$ at $[y_1] = [1 : 0 : \ldots : 0] \in \mathbb{P}(T_1)$.

For $\Gamma \in V_{\text{aff}}(n)$ the initial terms of the generators of the ideal $I_{\Gamma}$ coincide with those of $I_{\Gamma_p}$. More precisely, the generators of $I_{\Gamma}$ may be obtained by adding suitable multiples of the monomials $x_i x_n, i \geq 1$ to these initial terms. We may therefore write these generators in the form

$$x_i^2 - a_{(1,1)} x_1 x_n - a_{(1,2)} x_2 x_n - \ldots - a_{(1,n)} x_n^2,
$$

$$x_i x_j - a_{(i,j,1)} x_1 x_n - a_{(i,j,2)} x_2 x_n - \ldots - a_{(i,j,n)} x_n^2, \quad 1 \leq i < j \leq n - 1,
$$

$$x_i^2 - x_1 x_n - a_{(i,2)} x_2 x_n - \ldots - a_{(i,n)} x_n^2, \quad 2 \leq i \leq n - 1.$$  

Analyzing these equations of $\Gamma$ further, we see that the apolarity condition, i.e., that $I_{\Gamma,2} \subset q^1$, means that $a_{(1,1)} = 0$ and that $a_{(i,j,1)} = 0$ when $i \neq j$. Therefore they take the form

$$f_{11} = x_1^2 - a_{(1,2)} x_2 x_n - \ldots - a_{(1,n)} x_n^2,
$$

$$f_{12} = x_1 x_2 - a_{(2,2)} x_2 x_n - \ldots - a_{(2,n)} x_n^2,
$$

$$f_{22} = (x_2^2 - x_1 x_n) - a_{(2,2)} x_2 x_n - \ldots - a_{(2,n)} x_n^2,
$$

$$f_{13} = x_1 x_3 - a_{(3,2)} x_2 x_n - \ldots - a_{(3,n)} x_n^2,
$$

$$f_{23} = x_2 x_3 - a_{(3,3)} x_2 x_n - \ldots - a_{(3,n)} x_n^2,
$$

$$f_{33} = (x_3^2 - x_1 x_n) - a_{(3,3)} x_2 x_n - \ldots - a_{(3,n)} x_n^2,
$$

$$\vdots
$$

$$f_{(n-1)(n-1)} = (x_{n-1}^2 - x_1 x_n) - a_{((n-1)(n-1),2)} x_2 x_n - \ldots - a_{((n-1)(n-1),n)} x_n^2.$$  

To insure that these perturbed equations actually define length $n$ subschemes, we ask that the first order relations or syzygies among the generators of $I_{\Gamma_p}$ lift to the entire family. This is in fact precisely the requirement for the perturbation to define a flat family [Art76, Proposition 3.1], and will be pursued below when we find equations for $V_{\text{aff}}(n)$.

Here, we introduce weights and a torus action on this family: We give

- $x_n$ and $a_{(i,j)}$, where $2 \leq i, j, k \leq n - 1$, weight $1$,
- $x_i$, where $2 \leq i \leq n - 1$, and $a_{(i,j,1)}$, where $2 \leq i, j \leq n - 1$, weight $2$,
- $x_1$ and $a_{(1,n)}$ and $a_{(1,1)}$, where $2 \leq i \leq n - 1$, weight $3$. 

\[\text{Documenta Mathematica} 18 (2013) 469–505\]
Notice that with these weights each generator $f_{ij}$ is homogeneous. A $\mathbb{C}^*$-action defined by multiplying each parameter with a constant $\lambda^w$ to the power of its weight, acts on each generator by a scalar multiplication, i.e. on the total family in $\mathbf{P}(T_1) \times \mathcal{V}^{\text{aff}}_h(n)$. This $\mathbb{C}^*$-action induces an action on the family $\mathcal{V}^{\text{aff}}_h(n)$. In particular, if $[a] = [a_{(i,j,k)}] \in \mathcal{V}^{\text{aff}}_h(n)$ defines a subscheme $\Gamma[a]$, then $[\lambda^w(a)] = [\lambda^w(a_{(i,j,k)})] \in \mathcal{V}^{\text{aff}}_h(n)$ and defines a subscheme $\Gamma[\lambda^w a]$, such that $p' \in \Gamma[a]$ if and only if $\lambda^w(p') \in \Gamma[\lambda^w a]$.

Since $\lim_{\lambda \to 0} \lambda^w(a_{(i,j,k)}) = 0$, the limit when $\lambda \to 0$ of the $\mathbb{C}^*$-action is the point in $\mathcal{V}^{\text{aff}}_h(n)$ representing $\Gamma_p$. Thus we have shown

**Lemma 5.1.** The affine algebraic set $\mathcal{V}^{\text{aff}}_h(n)$ of apolar subschemes of length $n$ contained in $D(x_n)$ coincides with the apolar schemes of length $n$ whose equations are affine perturbations of the equations of $\Gamma_p$.

Furthermore, the family $\mathcal{V}^{\text{aff}}_h(n)$ is contractible to the point $[\Gamma_p]$.

An immediate consequence is the

**Corollary 5.2.** The apolar subscheme $\Gamma_p$ belongs to $\mathcal{V}^{\text{PS}}_Q(n)$. In particular, the variety of tangent spaces $TQ^{-1} \subset G(n-1,T_{q,2})$ to the Veronese embedding of the quadric $Q^{-1} \subset \mathbf{P}(T_{q,2})$ is a subvariety of $\mathcal{V}^{\text{PS}}_Q(n)$.

Notice that $\mathcal{V}^{\text{aff}}_h(n)$ depends only on $h$, and not on $p$. Only the coordinates on $\mathcal{V}^{\text{aff}}_h(n)$ depend on $p$. On the other hand, the contractible varieties $\mathcal{V}^{\text{aff}}_h(n)$ form a covering of $\mathcal{V}^{\text{APS}}_Q(n)$:

**Lemma 5.3.** If $h_j = \{l_j = 0\}, j = 1, \ldots, n^2$ is a collection of tangent hyperplanes to $Q^{-1}$, so that no subset of $n$ of them have a common point, then the open subvarieties $\mathcal{V}^{\text{aff}}_{h_j}(l_j)$ parametrizing apolar subschemes $Z$ of length $n$ with support in $D(l_j)$ form a covering of $\mathcal{V}^{\text{APS}}_Q(n)$ of isomorphic varieties.

**Proof.** If an apolar subscheme $\Gamma$ has $k \leq n$ components, then the collection of hyperplanes among the $\{l_j = 0\}$ that intersect $\Gamma$ is at most $k(n-1) < n^2$, so the $\mathcal{V}^{\text{aff}}_{h_j}(l_j)$ form a covering. The last part follows from the homogeneity. \qed

To find equations for the family $\mathcal{V}^{\text{aff}}_h(n)$, we use the parameters for the generators in (5.1), i.e.

$$a_{(i,j,k)} \quad i,j \in \{1,\ldots,n-1\}, \ 2 \leq k \leq n,$$

where we read the first index $(ij)$ as an unordered pair.
It will be useful to write the generators with matrices:

\[
\begin{pmatrix}
  f_{11} \\
  f_{12} \\
  f_{22} \\
  \vdots \\
  f_{(n-1)(n-1)}
\end{pmatrix} =
\begin{pmatrix}
  1 & 0 & \ldots & 0 & -a_{(1,2)} & \ldots & -a_{(1,n)} \\
  0 & 1 & \ldots & 0 & -a_{(2,2)} & \ldots & -a_{(2,n)} \\
  0 & 0 & \ldots & 0 & -a_{(2,2)} & \ldots & -a_{(2,n)} \\
  \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
  0 & 0 & \ldots & 1 & \vdots & \ldots & -a_{((n-1)(n-1),n)}
\end{pmatrix}
\begin{pmatrix}
  x_1 \\
  x_1 x_2 \\
  x_1^2 - x_1 x_n \\
  \vdots \\
  x_{n-1}^2 - x_1 x_n \\
  x_{n-1} x_n \\
  \vdots \\
  x_n^2 
\end{pmatrix}.
\]

We denote by $A_F$ the $(n^2) \times ((n^2) + n - 1)$-dimensional coefficient matrix of these generators. The maximal minors of $A_F$ are, of course, precisely the Plücker coordinates for $V_{h}^{\text{aff}}(n)$ in $G((n^2), q^{-})$, or equivalently in $G(n - 1, T_{2,q})$.

We find the equations of the family by asking that the first order syzygies among the generators of $I_{F_p}$ lift to the entire family. By [Art76, Proposition 3.1], this is precisely the requirement for the perturbation to define a flat family. We use a standard basis approach (cf. [Sch91]). The syzygies for a subscheme $Z$ in the family are all linear, and the initial terms are inherited from $\Gamma_p$.

Therefore, the difference between syzygies of $Z$ and syzygies of $\Gamma_p$ are only multiples of $x_n$. By the division theorem ([Sch91, Theorem A.3]), every syzygy has the initial term $x_k(x_i x_j)$, where $k > j \geq i$, and has the form

\[x_k f_{ij} = \sum_{st} g_{ij}^{st} f_{st}\]

where $f_{ij}$ is the generator with initial term $x_i x_j$ and $g_{ij}^{st}$ is a linear form such that $g_{ij}^{st} f_{st}$ has higher order than $x_k(x_i x_j)$. More precisely, we therefore consider products of the generators ($f_{ij}$) with a first order syzygy for $\Gamma_p$ and add precisely those multiples of $x_n$ in the syzygy that eliminates monomials $x_k x_i x_n$ with $k \leq l < n$ in the product. The relations among the parameters required for the lifting of the syzygies can then be read off as the coefficients of the monomials $x_i x_n^2$.

**Theorem 5.4.** The equations defining $V_{h}^{\text{aff}}(n)$ all lie in the linear span of the $2 \times 2$ minors of the coefficient matrix $A_F$ of the family of equations $f_{ij}$. In particular $V_{\text{APS}}(Q, n)$ is a linear section of the Grassmannian $G(n - 1, T_{2,q})$.

**Remark 5.5.** This generalizes the result of Mukai in case $n = 3$, cf. [Muk92]. For an exposition of different approaches to the $n = 3$ case, see [Dol12, Section 2.1.3].

**Proof.** Consider the following first order syzygies of $\Gamma_p$ of rank 2 and 3:

\[R_i \cdot S_i(m), 1 < i < n, m = 1, 2:\]

\[
\begin{pmatrix}
  x_i^2 & x_1 x_i & x_i^2 - x_1 x_n \\
  -x_i & x_n & x_i \\
  0 & x_1 & x_i
\end{pmatrix} = 0,
\]

where $S_i(m)$ is the $m$-th column vector in the syzygy matrix $S_i$. 
$R_{ij} \cdot S_{ij}(m), 1 < i < j < n, m = 1, \ldots, 4$:

$$(x_i^2 - x_1 x_n \ \ x_1 x_i \ \ x_1 x_j \ \ x_i x_j \ \ x_j^2 - x_1 x_n) \cdot \begin{pmatrix} x_j & 0 & 0 & 0 \\ 0 & x_n & x_j & 0 \\ x_n & 0 & -x_i & -x_i \\ -x_i & -x_j & 0 & x_1 \\ 0 & x_i & 0 & 0 \end{pmatrix} = 0,$$

and

$R_{ijk} \cdot S_{ijk}(m), 1 < i < j < k < n, m = 1, 2$:

$$(x_i x_j \ \ x_j x_k \ \ x_i x_k) \cdot \begin{pmatrix} -x_k & -x_k \\ x_i & 0 \\ 0 & x_j \end{pmatrix} = 0.$$
Similarly
\[ R_i \cdot S_i(2) = (a_{(i,j)} - a_{(i,n)}) x_i x_n^2 + a_{(i,n)} x_i x_n^2 + \sum_{j=2}^{n-1} (-a_{(i,j)} + \sum_{k=2}^{n-1} (a_{(i,k)} a_{(i,k,j)} - a_{(i,k)} a_{(i,j,k)})) x_i x_n^2, \]
\[ R_j \cdot S_j(1) = (a_{(j,i)} - a_{(j,n)}) x_j x_n^2 + a_{(j,n)} x_j x_n^2 + \sum_{i=2}^{n-1} (-a_{(j,i)} + \sum_{k=2}^{n-1} (a_{(j,k)} a_{(j,m,k)} - a_{(j,k)} a_{(j,m,i)})) x_j x_n^2, \]
\[ R_k \cdot S_k(1) = (a_{(k,i)} - a_{(k,n)}) x_k x_n^2 + a_{(k,n)} x_k x_n^2 + \sum_{i=2}^{n-1} (-a_{(k,i)} + \sum_{j=2}^{n-1} (a_{(k,j)} a_{(j,m,i)} - a_{(j,m)} a_{(j,m,i)})) x_k x_n^2, \]
\[ R_{ijk} \cdot S_{ijk}(1) = (a_{(i,k)} - a_{(i,j)}) x_i x_j x_k^2 + a_{(i,j)} x_i x_j x_k^2 + \sum_{m=2}^{n-1} (-a_{(i,k)} + \sum_{j=2}^{n-1} (a_{(j,m)} a_{(j,m,k)} - a_{(j,m)} a_{(j,m,i)})) x_i x_j x_k^2, \]
\[ R_{ijk} \cdot S_{ijk}(2) = (a_{(i,k)} - a_{(i,j)}) x_i x_j x_k^2 + a_{(i,j)} x_i x_j x_k^2 + \sum_{m=2}^{n-1} (-a_{(i,k)} + \sum_{j=2}^{n-1} (a_{(j,m)} a_{(j,m,k)} - a_{(j,m)} a_{(j,m,i)})) x_i x_j x_k^2. \]

The linear relations in the parameters of the family \( V_h^{\text{aff}}(n) \) are precisely the coefficients of \( x_i x_j x_k^2 \) in these products:

**Lemma 5.6.** The space of linear forms in the ideal of \( V_h^{\text{aff}}(n) \) is generated by the following forms, where \( \{i, j, k\} \) is any subset of distinct elements in \( \{2, \ldots, n-1\} \)

\[ a_{(i,j)} - a_{(i,n)}, a_{(i,n)} - a_{(i,n)} \]
\[ a_{(i,j)} - a_{(i,n)}, a_{(i,j)} - a_{(i,j,n)}, a_{(i,j)} - a_{(j,j,i)}, a_{(i,j,k)} - a_{(j,k,i)}. \]

Notice that only the first two occur when \( n = 3 \), and only the first four occur when \( n = 4 \).

Using these linear relations, the quadratic ones all become linear in the \( 2 \times 2 \) minors of the matrix \( A_F \) of coefficients \( a_{(i,j,k)} \), i.e. linear in the Pl"ucker coordinates. In fact, by a straightforward but tedious derivation from the above presentation, we may write the generators of the ideal \( V_h^{\text{aff}}(n) \) as linear combinations of \( 2 \times 2 \) minors in the coefficient matrix \( A_F \) (cf. the documented computer algebra code to perform the computation of ideal generators [RS11]):

**Lemma 5.7.** Modulo the linear forms the ideal of \( V_h^{\text{aff}}(3) \) is generated by
\[ a_{(1,3)} + a_{(2,3)} a_{(22,2)} - a_{(12,2)} a_{(22,3)}. \]

**Lemma 5.8.** Modulo the linear forms the ideal of \( V_h^{\text{aff}}(4) \) is generated by
\[ -a_{(12,2)} - a_{(13,3)} + (a_{(23,2)} a_{(22,3)} - a_{(22,2)} a_{(23,3)}) + (a_{(33,2)} a_{(23,3)} - a_{(23,3)} a_{(33,3)}), \]
\[ -a_{(13,3)} + (a_{(12,3)} a_{(23,3)} - a_{(23,3)} a_{(23,2)}) + (a_{(13,3)} a_{(33,3)} - a_{(33,3)} a_{(13,2)}), \]
\[ -a_{(11,3)} + (a_{(12,2)} a_{(22,2)} - a_{(22,2)} a_{(22,3)}) + (a_{(13,2)} a_{(23,3)} - a_{(23,3)} a_{(13,2)}), \]
\[ (a_{(11,3)} a_{(22,3)} - a_{(12,2)} a_{(23,3)} + a_{(13,3)} a_{(22,2)} - a_{(12,2)} a_{(23,3)}), \]
\[ (a_{(11,3)} a_{(22,3)} - a_{(12,2)} a_{(23,3)} + a_{(13,3)} a_{(22,2)} - a_{(12,2)} a_{(23,3)}), \]
\[ a_{(11,4)} + (a_{(12,4)} a_{(22,2)} - a_{(22,4)} a_{(22,2)}) + (a_{(13,4)} a_{(22,3)} - a_{(22,4)} a_{(13,2)}), \]
\[ a_{(11,4)} + (a_{(12,4)} a_{(23,3)} - a_{(23,4)} a_{(12,3)}) + (a_{(13,4)} a_{(33,3)} - a_{(33,4)} a_{(13,3)}). \]
LEMMA 5.9. Modulo the linear forms the ideal of $V_h^{aff}(n)$, when $n > 4$, is generated by the following forms:

For $i \in \{2, \ldots, n-1\}$,

$$a_{(1,1),n} - \sum_{m=2}^{n-1} (a_{(im,n)}a_{(1m,i)} - a_{(1m,n)}a_{(im,i)}),$$

for any subset $\{i,j\} \subset \{2, \ldots, n-1\}$,

$$a_{(1,1),i} - \sum_{m=2}^{n-1} (a_{(jm,n)}a_{(im,j)} - a_{(im,n)}a_{(jm,j)}),$$

and

$$n-1 \sum_{m=2}^{n-1} (a_{(1m,n)}a_{(im,j)} - a_{(im,n)}a_{(1m,j)})$$

and

$$a_{(1i,j)} + a_{(1j,i)} - \sum_{m=2}^{n-1} (a_{(jm,i)}a_{(im,j)} - a_{(im,i)}a_{(jm,j)}),$$

for any subset $\{i,j,k\} \subset \{2, \ldots, n-1\}$,

$$a_{(1j,k)} - \sum_{m=2}^{n-1} (a_{(jm,i)}a_{(im,k)} - a_{(im,i)}a_{(jm,k)}),$$

and

$$n-1 \sum_{m=2}^{n-1} (a_{(jm,n)}a_{(im,k)} - a_{(im,n)}a_{(jm,k)}),$$

and for any subset $\{i,j,k,l\} \subset \{2, \ldots, n-1\}$,

$$n-1 \sum_{m=2}^{n-1} (a_{(im,j)}a_{(km,l)} - a_{(km,j)}a_{(im,l)}).$$

Since the open affine sets $V_h^{aff}(n)$ cover $VAPS(Q,n)$, we conclude that $VAPS(Q,n)$ is a linear section of the Grassmannian $\mathbb{G}((\mathbb{C}^n)^q, q^-$). Equivalently, $VAPS(Q,n)$ is projectively equivalent to a linear section of $\mathbb{G}(n-1, T_{2,q})$ in its Plücker embedding. This concludes the proof of Theorem 5.4. □

Using the linear relations we may reduce the number of variables, when $n > 4$, and use as indices the following unordered three element sets:

$$\mathcal{I} = \{\{1k\}|1 < k \leq n\} \cup \{\{1j\}|1 < j < n\} \cup \{\{ijk\}|1 < i < j < k < n\}. $$

Let $R = \mathbb{C}[a_I | I \in \mathcal{I}]$. We substitute $a_{11k} = a_{11,k}, a_{1jk} = a_{1j,k}, a_{ijk} = a_{ij,k}$ and get:
Lemma 5.10. The ideal of $V^\text{aff}_h(n)$, when $n > 4$, is generated by the following polynomials in $R$: For $i \in \{2, \ldots, n-1\}$,
\[
a_{11n} - \sum_{m=2}^{n-1} (a_{1im}^2 - a_{1ln} a_{im}),
\]
for any subset $\{i, j\} \subset \{2, \ldots, n-1\}$,
\[
a_{11i} - \sum_{m=2}^{n-1} (a_{1jm} a_{ijm} - a_{1im} a_{jjm}),
\]
\[
\sum_{m=2}^{n-1} (a_{11m} a_{ijm} - a_{1jm} a_{1jm}),
\]
for any subset $\{i, j, k\} \subset \{2, \ldots, n-1\}$,
\[
a_{1jk} - \sum_{m=2}^{n-1} (a_{ijm} a_{ikm} - a_{ijm} a_{jkm}),
\]
\[
\sum_{m=2}^{n-1} (a_{1jm} a_{ikm} - a_{1im} a_{jkm}),
\]
\[
\sum_{m=2}^{n-1} (a_{ijm} a_{kjm} - a_{ijm} a_{kjm}).
\]
\[\square\]

Notice that these generators are all homogeneous in the weights introduced above. The linear parts of the ideal generators define the tangent space of the family $V^\text{aff}_h(n)$ at $[\Gamma_p]$, so another consequence of our computations is the tangent space dimension.

Proposition 5.11. Let $L(n)$ be the space of linear forms spanned by the linear parts of the generators in the ideal of $V^\text{aff}_h(n)$. Then $L(3)$ is spanned by
\[
a_{(11,3)}, \quad a_{(11,2)} - a_{(12,3)} \quad \text{and} \quad a_{(12,2)} - a_{(22,3)},
\]
$L(4)$ is spanned by
\[
a_{(11,4)}, \quad a_{(11,2)}, \quad a_{(12,4)}, \quad a_{(11,3)}, \quad a_{(13,4)}, \quad a_{(12,2)} - a_{(22,4)}, \quad a_{(13,3)} - a_{(33,4)}, \quad a_{(12,2)} + a_{(13,3)},
\]
\[
a_{(12,3)} - a_{(23,4)}, \quad a_{(13,2)} - a_{(12,3)}, \quad a_{(23,3)} - a_{(33,2)} \quad \text{and} \quad a_{(22,3)} - a_{(23,2)},
\]
$L(n)$, when $n > 4$, is spanned by $a_{(11,n)}$ and for any $i \in \{2, \ldots, n-1\}$,
\[
a_{(11,i)}, a_{(11,1)}, a_{(11,1)}, a_{(ii,1)}, a_{(ii,i)},
\]
for any subset $\{i, j\} \subset \{2, \ldots, n-1\}$,
\[
a_{(1j,1)}, a_{(ij,1)}, a_{(ij,i)} - a_{(ij,i)},
\]
and for any subset $\{i, j, k\} \subset \{2, \ldots, n-1\}$,
\[
a_{(ij,k)} - a_{(jk,i)}.
\]
In particular
\[ V_{h}^{\text{aff}}(3) \cong \mathbf{A}^3, \quad V_{p}^{\text{aff}}(4) \cong \mathbf{A}^6, \quad V_{h}^{\text{aff}}(5) \cong \mathbf{A}^{10}. \]

Proof. The linear parts of the generators can be read off Lemma 5.6 and Lemmas 5.7, 5.8 and 5.9. Notice only that the two term forms
\[ a_{(12,2)} - a_{(22,4)}, \quad a_{(13,3)} - a_{(33,4)}, \quad a_{(12,2)} + a_{(13,3)} \]
span a three dimensional space, while
\[ a_{(1i,i)} - a_{(ii,n)}, \quad a_{(jj,j)} - a_{(jj,n)}, \quad a_{(1i,i)} + a_{(1j,j)}, \quad \text{for } 1 < i < j < n \]
span the space generated by
\[ a_{(1i,i)}, \quad a_{(ii,n)}, \quad 1 < i < n \]
when \( n > 4 \).

For \( n = 3 \), the family \( V_{h}^{\text{aff}}(3) \) has 6 parameters, while there are three independent linear forms in the relations so the tangent space at \([\Gamma_p]\) has dimension \( 6 - 3 = 3 \) as expected. In fact \( V_{h}^{\text{aff}}(3) \cong \mathbf{A}^3 \) with parameters
\[ a_{(11,2)}, a_{(12,2)}, a_{(22,2)}. \]

For \( n = 4 \) the family \( V_{h}^{\text{aff}}(4) \) has 18 parameters, while the linear forms in the relations are generated by 12 independent forms, so the tangent space at \([\Gamma_p]\) has dimension \( 18 - 12 = 6 \). In fact \( V_{h}^{\text{aff}}(4) \cong \mathbf{A}^6 \) with parameters
\[ a_{(12,2)}, a_{(12,3)}, a_{(23,3)}, a_{(22,3)}, a_{(22,2)}, a_{(33,3)}. \]

For \( n > 4 \) we see that all parameters with a 1 or an \( n \) in the index are independent forms in the space of linear parts of ideal generators in \( V_{h}^{\text{aff}}(n) \). Furthermore, the other linear parts, simply expresses that \( \{(ijk)|1 < i < j < k < n\} \) form a natural index set for representatives of the parameters. The cardinality of this index set is simply the cardinality of monomials of degree 3 in \( n - 2 \) variables, i.e. \( \binom{n}{3} \). In case \( n = 5 \) we again conclude that \( V_{h}^{\text{aff}}(5) \cong \mathbf{A}^{10} \) with parameters
\[ \{a_{ijk}|2 \leq i \leq j \leq k \leq 4\}. \]

\[ \square \]

Corollary 5.12. The tangent space dimension of \( \text{VAPS}(Q,n) \) at \([\Gamma_p]\) is \( \begin{pmatrix} n \\ 3 \end{pmatrix} \) when \( n > 5 \). When \( n \leq 5 \), \( \text{VAPS}(Q,n) \) has a finite cover of affine spaces, in particular \( \text{VAPS}(Q,n) \) is smooth and coincides with \( \text{VPS}(Q,n) \).

Remark 5.13. Let \( \Gamma \) be a smooth apolar subscheme to \( Q \) consisting of \( n \) distinct points. Any subset of \( n - 2 \) points in \( \Gamma \) is contained in a pencil of apolar subschemes that form a line in \( \text{VPS}(Q,n) \) through \([\Gamma]\). Thus \( \begin{pmatrix} n \\ 2 \end{pmatrix} \) lines in \( \text{VPS}(Q,n) \) through \([\Gamma]\) is contained in the tangent space at \([\Gamma]\).

We extend this remark and give a conceptual reason for the dimension of the tangent space to \( \text{VAPS}(Q,n) \) at \([\Gamma_p]\).
Proposition 5.14. Let $[\Gamma_p] \in VPS(Q,n) \subset G(n-1, T_{2,q})$ be a point on the subvariety $TQ^{-1}$ in its Grassmannian embedding. Then $VPS(Q,n)$ contains the cone over a 3-uple embedding of $P^{n-3}$ with vertex at $[\Gamma_p]$.\\

Proof. We first identify a cone over a 3-uple embedding of $P^{n-3}$ inside $VAPS(Q,n)$, and then give an explicit description of the apolar subschemes parameterized by this cone in order to show that the cone is contained in $VPS(Q,n)$.\\

Consider the subvariety $V_{p \text{vero}}(n) \subset V_{\text{aff}}^{\text{geo}}(n)$ parameterizing ideals $I_{\Gamma}$ with coefficient matrix $A_{p}(G) = (I A)$ where the submatrix $A = (a_{ij,k})$ has rank at most 1 and has nonzero entries only in the submatrix $A_0 \subset A$ with entries $\{a_{ij,k} | 1 \leq i < j < n, 1 < k < n\}$. As above, using the linear relations, we may substitute the parameters $a_{ij,k}$ with parameters $a_{ijk}$ whose indices are unordered triples $(ijk)$. In these new parameters the matrix $A_0$ takes the form:

$$
A_0 = \begin{pmatrix}
a_{222} & a_{223} & \cdots & a_{22(n-1)} \\
a_{223} & a_{333} & \cdots & a_{23(n-1)} \\
\vdots & \vdots & \ddots & \vdots \\
a_{22(n-1)} & a_{23(n-1)} & \cdots & a_{2(n-1)(n-1)} \\
a_{2(n-1)(n-1)} & a_{3(n-1)(n-1)} & \cdots & a_{(n-1)(n-1)(n-1)}
\end{pmatrix}.
$$

By Theorem 5.4, the equations of $V_{\text{aff}}^{\text{geo}}(n)$ are linear in the 2 × 2 minors of the coefficient matrix $A$, so any rank 1 matrix $A_0$ defines a point on $V_{p \text{vero}}(n)$. The symmetry in the indices explains why the 2 × 2 minors of the matrix define the 3-uple embedding of $P^{n-3}$. Since the ideal of $\Gamma_p$ correspond to the zero matrix, we conclude that the subvariety $V_{p \text{vero}}(n)$ in $VAPS(Q,n)$ is the cone over this 3-uple embedding.\\

To see that $V_{p \text{vero}}(n)$ is contained in $VPS(Q,n)$ we show that a general point on $V_{p \text{vero}}(n)$ lies in the closure of smooth apolar subscheme to $Q$. For this, we describe for each general point $s \in P^{n-3}$ an apolar subscheme $\Gamma_s$ belonging to $V_{p \text{vero}}(n)$. It has two components $\Gamma_s = \Gamma_{s,0} \cup p_s$, the first one $\Gamma_{s,0}$ of length $n-1$ and supported at $p$, while the second component $p_s$ is a closed point. We shall show that $q$ has a decomposition $q = q_l + q(l)^2 \in T_2$ where $[q(l)] = p_l \in P(T_1)$ and $q_l \in (l^2)^2$. The subscheme $\Gamma_{s,0}$ is apolar to $q_l$ and contains the first order neighborhood of $p$ inside the quadric $\{q_l^{-1} = 0\} \subset P(l^2)$ in the hyperplane polar to $p_s$. Then $\Gamma_{s,0}$ lies in the closure of smooth apolar subschemes to $q_l$.\\

We conclude by applying Proposition 2.4.\\
Let $s = [s_2 : \ldots : s_{n-1}] \in P^{n-3}$ and let

$$
||s||^2 = s_2^2 + \ldots + s_{n-1}^2, \quad \langle s, x \rangle = \sum_{i=2}^{n-1} s_i x_i, \quad \langle s, y \rangle = \sum_{i=2}^{n-1} s_i y_i,
$$

then

$$
x_i^2 - x_1 x_n - s_i^2 \langle s, x \rangle x_n \quad 1 < i < n, \quad x_i x_j - s_i s_j \langle s, x \rangle x_n \quad 1 < i < j < n
$$
defines a subscheme \( \Gamma_s \) that belongs to \( V_{p_{\text{vero}}}^n(\mathbb{P}) \). When \( ||s||^2 \neq 0 \), then \( \Gamma_s \) contains the point

\[ p_s = [q(||s||^2(s, x) + x_1)] = [||s||^2(s, y) + y_n] \in \mathbb{P}(T_1) \]

Consider the linear subspace \( L_s = \{x_1 = 0\} \cap \{s, x = 0\} \). The intersection \( \Gamma_s \cap L_s \) is the subscheme defined by

\[ x_2^2 = x_2x_3 = \ldots = x_{n-1}^2 = 0. \]

This subscheme has length \( n - 2 \). The union \( p_s \cup (\Gamma_s \cap L_s) \) spans the hyperplane \( \{x_1 = 0\} \), so the residual point in \( \Gamma_s \) is the pole, with respect to \( Q^{-1} \), of this hyperplane, i.e. the point \( p \). Therefore the subscheme \( \Gamma_{s,0} = \Gamma_s \setminus p_s \) has length \( n - 1 \), is supported in \( p \), and contains the first order neighborhood of \( p \) in the codimension two linear space \( L_s \).

The subscheme \( \Gamma_{s,0} \) is apolar to the quadric

\[ q_s = (||s||^2(s, y) + y_n)^2 - ||s||^9(2y_1y_n + y_2^2 + \ldots + y_{n-1}^2). \]

Let \( l = ||s||^2(s, x) + x_1 \). Then \( p_s = [q(l)] \), while

\[ l_1^2 = \langle y_2 - ||s||^2s_1y_1, \ldots, y_{n-1} - ||s||^2s_1y_1, y_n \rangle. \]

Then \( q_s \in (l_1^2)^2 < 2 \) and

\[ (q(l))^2 - q_s = ||s||^9 \cdot q \in T_2. \]

According to Proposition 2.4 a subscheme \( \Gamma_0 \) in \( \mathbb{P}(l_1^2) \) of length \( n - 1 \) is apolar to \( q_s \) if and only if \( \Gamma = \Gamma_0 \cup p_s \) is apolar to \( q \). Now, \( \Gamma_{s,0} \) is apolar to \( q_s \) and contains a first order neighborhood of a point on the smooth quadric \( \{q_s^{-1} = 0\} \) in \( \mathbb{P}(l_1^2) \subset \mathbb{P}(T_1) \). By Remark 3.5, the subscheme \( \Gamma_{s,0} \) is a subscheme like \( \Gamma_p \), with respect to \( q_s \). Therefore \( \Gamma_{s,0} \) lies in the closure of smooth apolar subschemes to \( q_s \). But then \( \Gamma_s \) must lie in the closure of smooth apolar subschemes to \( q \). Hence \( [\Gamma_s] \in VPS(q, n) \).

\[ \square \]

**Corollary 5.15.** \( VPS(Q, n) \) is singular when \( n \geq 6 \).

**Proof.** The cone with vertex at \( [\Gamma_p] \in TQ^{-1} \) over the 3-uple embedding of \( \mathbb{P}^{n-3} \) is contained in the tangent space of \( VPS(Q, n) \) at \( [\Gamma_p] \), i.e. also in the tangent space of \( VAPS(Q, n) \). Since the span of the cone and the tangent space of the latter have the same dimension, they coincide. In particular the tangent space of \( VPS(Q, n) \) at \( [\Gamma_p] \) has dimension \( \binom{n}{3} \). When \( n \geq 6 \), then \( \binom{n}{3} > \binom{6}{3} = \dim VPS(Q, n) \) so \( VPS(Q, n) \) is singular.

\[ \square \]

We pursue the case \( n = 6 \) a bit further and show that \( VAPS(Q, 6) \) and \( VPS(Q, 6) \) coincide. We use the symmetric variables

\[ a_{ijk} = a_{(i,j,k)}, \ 1 \leq i, j, k \leq 6 \]

for any permutation of the letters \( i, j, k \). According to Lemma 5.10 we may list the generators explicitly. This list is however not minimal. In fact, a minimal set of generators is given by the following twenty generators in weight 2, four generators in weight 3 and one generator in weight 4. The twenty generators
of weight 2 are the generators of weight 2 in Lemma 5.10: For each \(1 < k < 6\), and each pair \(\{i, j\} \subset \{2, 3, 4, 5\} \setminus \{k\}\) the generator

\[-a_{ij6} + \sum_{m=2}^{5} (a_{ikm}a_{jkm} - a_{ijm}a_{km})\]

for each pair \(\{i, j\} \subset \{2, 3, 4, 5\}\) the generator

\[-a_{ii6} - a_{jj6} + \sum_{m=2}^{5} (a_{ijm}a_{ijm} - a_{iim}a_{jjm})\]

and additionally the two generators

\[\sum_{m=2}^{5} (a_{23m}a_{45m} - a_{24m}a_{35m})\]

and

\[\sum_{m=2}^{5} (a_{23m}a_{45m} - a_{25m}a_{34m}).\]

The last five generators are computed from the list of Lemma 5.10 using Macaulay2 \([GS]\), see the documented code in \([RS11]\).

Of weight 3 we find, for \(i = 2, 3, 4\):

\[a_{11i} - \sum_{m=2}^{5} (a_{im6}a_{m55} - a_{m56}a_{im5})\]

and

\[a_{115} - \sum_{m=2}^{5} (a_{m46}a_{m45} - a_{m56}a_{m44}).\]

The generator of weight 4 is

\[a_{116} - \sum_{m=2}^{5} a_{m56}^2 + \sum_{m=2}^{5} a_{11m}a_{m55}.\]

The ten parameters with 6 in the index appear linearly in the 20 generators of weight 2, while the five parameters with 11 in the index appear linearly in the five generators of weights 3 and 4. The remaining 10 generators of weight 2 therefore depend only on 20 parameters \(a_I\). In fact they depend only on 16 linear forms. It is a remarkable fact that these ten quadratic forms define the 10-dimensional spinor variety. To see this we choose and rename the following 16 forms:

\[x_{1234} = -a_{353} + a_{252}, \quad x_{15} = -a_{555} + a_{454} + a_{353} + a_{252}, \quad x_{34} = a_{453},\]

\[x_{1235} = a_{554} - a_{444} + a_{343} + a_{242}, \quad x_{14} = a_{343} - a_{242}, \quad x_{35} = a_{553} - a_{232},\]

\[x_{1245} = -a_{553} - a_{443} + a_{333} - a_{232}, \quad x_{13} = a_{553} - a_{443}, \quad x_{24} = a_{453},\]

\[x_{1345} = a_{552} + a_{442} + a_{332} - a_{222}, \quad x_{12} = a_{552} - a_{442}, \quad x_{23} = a_{352},\]

\[x_{2345} = a_{454} - a_{353}, \quad x_{45} = a_{554} - a_{242}, \quad x_{25} = -a_{442} + a_{332}, \quad x_{0} = a_{342}.\]

In these variables the ten quadratic generators takes the form

\[q_0 = x_{25}x_{34} - x_{35}x_{24} + x_{45}x_{23} + x_{2345}x_{0},\]

\[q_1 = -x_{45}x_{13} + x_{14}x_{35} - x_{15}x_{34} + x_{1345}x_{0}.\]
We will do the explicit computation in the cases where \( Pfaffians \). The ten quadratic forms satisfy the following quadratic relation

\[
q_2 = x_{45}x_{12} + x_{14}x_{25} + x_{15}x_{24} + x_{1245}x_0,
q_3 = -x_{35}x_{12} + x_{13}x_{25} - x_{15}x_{23} + x_{1235}x_0,
q_4 = x_{12}x_{34} - x_{13}x_{24} + x_{14}x_{23} + x_{1234}x_0,
q_5 = x_{1345}x_{12} + x_{1245}x_{13} + x_{1235}x_{14} + x_{15}x_{1234},
q_6 = -x_{2345}x_{12} + x_{1245}x_{23} + x_{1235}x_{24} + x_{1234}x_{25},
q_7 = -x_{2345}x_{13} - x_{1345}x_{23} + x_{1235}x_{34} + x_{1234}x_{35},
q_8 = -x_{2345}x_{14} - x_{1345}x_{24} - x_{1245}x_{34} + x_{1234}x_{45},
q_9 = -x_{15}x_{2345} - x_{1345}x_{25} - x_{1245}x_{35} - x_{1235}x_{45}.
\]

The first five express (when \( x_0 = 1 \)) the variables \( x_{ijkl} \) as quadratic Pfaffians in the \( x_{st} \), while the last five quadrics express the linear syzygies among these Pfaffians. The ten quadratic forms satisfy the following quadratic relation

\[
q_9q_5 + q_1q_6 + q_2q_7 + q_3q_8 + q_4q_9 = 0.
\]

In fact the ten quadratic forms generate the ideal of the 10-dimensional spinor variety embedded in \( \mathbb{P}^{15} \) by its spinor coordinates [RS00, Section 6],[Muk95].

**Corollary 5.16.** \( V_{h}^{af}(6) \) is isomorphic to a cone over the ten-dimensional spinor variety embedded in \( \mathbb{P}^{15} \) by its spinor coordinates. In particular \( VAPS(Q,6) \) is singular, irreducible and coincides with \( VPS(Q,6) \).

We end this section summarizing some computational results, for small \( n \), of some natural subschemes of \( VAPS(Q,n) \). The first is the punctual part \( V_{p}^{loc}(n) \) of \( VAPS(Q,n) \), i.e. the variety of apolar subschemes in \( VAPS(Q,n) \) with support at a single point \( p \). The support \( p \) of a local apolar subscheme must lie on \( Q^{-1} \) by Lemma 2.3. Therefore we may assume that \( p = [0:0:...:1] \), and use the equations 5.1. Of course, \( [\Gamma] \) is then in \( V_{p}^{loc}(n) \). Furthermore, \( V_{p}^{loc}(n) \) is naturally contained in a second natural subscheme of \( VAPS(Q,n) \), namely \( V_{p}^{sec}(n) \), the variety of apolar subschemes in \( V_{h}^{af}(n) \) that contains the point \( p \).

We will do the explicit computation in the cases where \( VAPS(Q,n) = VPS(Q,n) \) is smooth, i.e. when \( n < 6 \). An apolar subscheme in \( V_{h}^{af}(n) \) lies in \( V_{p}^{sec}(n) \) if and only if the term \( x_{n}^2 \) does not appear in any equation, so \( V_{p}^{sec}(n) \) is defined by the equations \( a_{i,j,n} = 0 \) for \( 1 \leq i \leq j < n \) in \( V_{h}^{af}(n) \). The linear relations then imply that \( a_{1,i,j} = 0 \) for all \( i,j \), and as before that each parameter \( a_{i,j,k} \) with \( 1 < i,j,k < n \) may be represented by a parameter

\[
a_{ijk} \text{ with } 1 < i \leq j \leq k < n.
\]

In particular for \( n = 3 \) the only parameter left is \( a_{222} \), and \( V_{p}^{sec}(3) \) is isomorphic to the affine line. The equations \( x_{1}^2 = x_{1}x_{2} = x_{2}^2 - x_{1}x_{3} = a_{222}x_{2}x_{3} \) define a scheme supported at \( p \) only if \( a_{222} = 0 \), so \( V_{p}^{loc}(n) \) is a point in the case \( n = 3 \). The computation of \( V_{p}^{sec}(n) \) follow the same procedure for every \( n \). For a local scheme \( \Gamma \) in \( V_{p}^{loc}(n) \) we may set \( x_{n} = 1 \) in the equations.

**Lemma 5.17.** A local scheme \( \Gamma \), supported at \( p \), that belongs to \( V_{p}^{loc}(n) \), is Gorenstein. The maximal ideal of its affine coordinate ring is spanned by \( x_{2}, \ldots, x_{n-1}, x_{1} \), and its socle is generated by \( x_{1} \).
The scheme $\Gamma$ is Gorenstein by Lemma 2.6. The maximal ideal is certainly generated by $x_1, x_2, \ldots, x_{n-1}$, and since $\Gamma$ is nondegenerate these are linearly independent. Finally, $x_1 x_i = 0$ for all $i$ by the apolarity condition as soon as $p \in \Gamma$, so the socle is generated by $x_1$.

We may now get explicit equations for $V_p^{loc}(n)$. If $[\Gamma] \in V_p^{loc}(n)$, then by definition $m_p^n = 0$. But the maximal ideal is generated by $x_1, x_2, \ldots, x_{n-1}$, so this means that any monomial of degree $n$ in the $x_i$ must vanish in the coordinate ring of $\Gamma$.

On the other hand, the equations for $\Gamma$ define the products $x_i x_j = \sum_{k=2}^{n-1} a_{ijk} x_k$ and $x_i^2 = x_1 + \sum_{k=2}^{n-1} a_{iik} x_k$ in this ring. Therefore, by iteration, we get polynomial relations in the parameters $a_{ijk}$. Imposing the apolarity condition, symmetrizing the parameters and adding the equations for $V_p^{sec}(n)$, then after, possibly, saturation we get set theoretic equations for $V_p^{loc}(n)$.

When $n = 4$ we have the parameters $a_{222}, a_{223}, a_{233}, a_{333}$ for $V_p^{sec}(4)$ and the relation

$$a_{223}^2 - a_{222} a_{233} + a_{233}^2 - a_{222} a_{333}.$$

Thus $V_p^{sec}(4)$ is a quadric hypersurface in $\mathbb{A}^4$.

For $V_p^{loc}(4)$ we first get the subscheme defined by the equations

$$x_1^2 = x_1 x_2 = x_1 x_3 = 0$$

and

$$x_2^2 = x_1 + a_{222} x_2 + a_{223} x_3, x_2 x_3 = a_{223} x_2 + a_{233} x_3; x_3^2 = x_1 + a_{233} x_2 + a_{333} x_3.$$

The coefficient of $x_1$ using these relations iteratively to compute $x_2^2, \ldots, x_4^2$, must vanish, so it yields the equations $a_{222} + a_{233} = a_{223} + a_{333} = a_{233}^2 + a_{223}^2 = 0$. The other coefficients give no additional relations, and neither does the equations for $V_p^{sec}(4)$, so $V_p^{loc}(4)$ is 1-dimensional and consists of a pair of affine intersecting lines.

When $n = 5$, the computation becomes a bit more involved. There are ten parameters $a_{ijk}$. The equations of $V_p^{sec}(5)$ are

$$a_{234}^2 - a_{233} a_{244} + a_{334}^2 - a_{333} a_{344} + a_{344}^2 - a_{334} a_{444} = 0,$$

$$a_{224} a_{234} - a_{223} a_{244} + a_{234} a_{334} - a_{233} a_{344} + a_{244} a_{334} - a_{234} a_{444} = 0,$$

$$a_{224} a_{233} - a_{223} a_{234} + a_{234} a_{333} - a_{233} a_{334} + a_{244} a_{334} - a_{234} a_{344} = 0,$$

$$a_{234}^2 + a_{224}^2 - a_{222} a_{244} + a_{244}^2 - a_{223} a_{334} - a_{224} a_{444} = 0,$$

$$a_{223} a_{224} - a_{223} a_{234} + a_{234} a_{344} - a_{233} a_{344} = 0,$$

$$a_{223}^2 - a_{222} a_{233} + a_{233}^2 - a_{222} a_{333} - a_{223} a_{333} + a_{224} a_{334} + a_{224}^2 = 0.$$

They define in $\mathbb{A}^{10}$ the affine cone over the intersection of the Grassmannian variety $G(2, 5)$ with a quadric. For $V_p^{loc}(5)$ there are additional equations defining the cone over the tangent developable of a rational normal sextic curve, a
codimension 3 linear section of $V^\sec_p(5)$. The cone over the rational normal curve parameterizes local apolar subschemes that are not curvilinear. For the computations in Macaulay2 [GS], see the documented code in [RS11]. The findings are summarized in Table 1.

6. Global invariants of $VPS(Q,n)$

We consider $VPS(Q,n)$ as a subscheme of $\mathbb{G}(n-1,T_2,q)$, and the incidence

$I_{Q}^{VPS} = \{(\gamma',\Gamma) | (\gamma') \subset (\Gamma) \} \subset \mathbb{P}(T_2,q) \times VPS(Q,n)$.

The incidence is a projective bundle,

$I_{Q}^{VPS} = \mathbb{P}(E_Q) \rightarrow VPS(Q,n)$,

while the first projection is birational (the rational map $\gamma : \mathbb{P}(T_2,q) \dashrightarrow VPS(Q,n)$ factors through the inverse of this projection). Denote by $L$ the tautological divisor on $\mathbb{P}(E_Q)$. It is the pullback of the hyperplane divisor on $\mathbb{P}(T_2,q)$. When $VPS(Q,n)$ is smooth,

$Pic(I_{Q}^{VPS}) \cong Pic(VPS(Q,n)) \oplus \mathbb{Z}[L]$.

Recall from Lemma 4.9, that the set $H_h \subset VPS(Q,n)$ of subschemes $\Gamma$ that intersects a hyperplane $h \subset \mathbb{P}(T_1)$ form a Plücker divisor restricted to $VPS(Q,n)$. Therefore the class of the Plücker divisor coincides with the first Chern class $c_1(E_Q)$.

**Theorem 6.1.**

i) $Pic(VPS(Q,4) \cong Pic(VPS(Q,5)) \cong \mathbb{Z}$.

ii) The ample generator $H$ is very ample, and $VPS(Q,4)$ and $VPS(Q,5)$ are Fano-mapsfolds of index 2.

iii) The boundary in $VPS(Q,n)$ consisting of singular apolar subschemes is, when $n \leq 5$, an anticanonical divisor.

**Proof.** i) Let $n = 4$ or $n = 5$. Then the Plücker divisor $H$ is very ample by the above. Furthermore, the complement $V^\text{aff}_p$ of the special Plücker divisor defined by a tangent hyperplane to $Q^{-1} \subset \mathbb{P}(T_1)$, the divisor $H_{(x_n=0)}$ in the

Table 1.
above notation, is isomorphic to affine space by Proposition 5.11. Therefore the Picard group has rank 1 as soon as this special Plücker divisor is irreducible. The tangent hyperplanes to $Q^{-1}$ cover all of $P(T_1)$, so the corresponding Plücker divisors cover $VPS(Q,n)$. Furthermore, for any subscheme $\Gamma$ in $VPS(Q,n)$, there is a tangent hyperplane that does not meet $\Gamma$, so these special Plücker divisors have no common point on $VPS(Q,n)$. Assume that the special Plücker divisors are reducible, then we may write $H = H_1 + H_2$, where both $H_1$ and $H_2$ moves without base points on $VPS(Q,n)$. Since $H \cdot l = 1$ for every line on $VPS(Q,n)$, only one of the two components can have positive intersection with a line. The other, say $H_2$, must therefore contain every line that it intersects. But this is impossible, since $H_2$ must contain all of $VPS(Q,n)$, by the following lemma:

**Lemma 6.2.** Any two polar simplices $\Gamma$ and $\Gamma'$ are connected by a sequence of lines in $VPS(Q,n)$.

**Proof.** This is immediate when $n = 2$. For $n > 2$, let $[l] \in \Gamma$ and $[l'] \in \Gamma'$, and let $P(U) = h_1 \cap h_U \subseteq P(T_1)$ be the intersection of their polar hyperplanes. Then $q = l^2 + l_1^2 + qv = (l')^2 + (l_1')^2 + qv$ for $qv \in U^2$ and suitable $l_1$ and $l_1'$. Let $\Gamma_U$ be a polar simplex for $qv$. Then $\Gamma$ is line connected to $\Gamma_U \cup \{[l_1],[l]\}$ by induction hypothesis. Likewise $\Gamma$ is line connected to $\Gamma_U \cup \{[l],[l']\}$. Finally $\Gamma_U \cup \{[l],[l]\}$ and $\Gamma_U \cup \{[l_1],[l']\}$ span a line in $VPS(Q,n)$, which completes the induction. □

ii) Since Pic$(t^{VPS}_Q) \cong \text{Pic}(VPS(Q,n)) \oplus \mathbb{Z}[L]$ we deduce from i) that the birational morphism

$$\sigma : t^{VPS}_Q \rightarrow P(T_{2,q})$$

has an irreducible exceptional divisor. Let $E \in \text{Pic}(t^{VPS}_Q)$ be the class of this exceptional divisor. Then, since the map $\gamma : P(T_{2,q}) \dashrightarrow G(n-1,T_{2,q})$ is defined by polynomials of degree $\binom{n}{2}$, the size of the minors in the Mukai form, we have

$$\pi^*H = \left(\begin{array}{c} n \\ 2 \end{array}\right) L - E \text{ and } K^{VPS}_Q = -\left(\begin{array}{c} n + 1 \\ 2 \end{array}\right) - 1)L + E.$$ 

On the other hand $H = c_1(E_Q)$ where $I^{VPS}_Q = P(E_Q)$ is a projective bundle over $VPS(Q,n)$ so

$$-\left(\begin{array}{c} n + 1 \\ 2 \end{array}\right) - 1)L + E = K^{VPS}_Q = \pi^*K_{VPS} + \pi^*(c_1(E_Q)) - (n - 1)L.$$

Therefore $-K_{VPS(Q,n)} = 2H$. Finally, since $VPS(Q,n) \subseteq G(n-1,T_{2,q})$ contains lines, $H$ is not divisible.

iii) The boundary in $VPS(Q,n)$ consisting of singular apolar subschemes, coincides, by Lemma 2.3, with the set of subschemes $\Gamma \subset P(T_1)$ that intersect quadric $Q^{-1}$. The Plücker divisor $H$ is represented by the divisor of subschemes $\Gamma$ that intersect a hyperplane in $P(T_1)$, so $-K = 2H$ is represented by the boundary. □
Let $n > 2$ and let $VPS(Q, n) \subset G(n - 1, T_{2,q})$ be the variety of polar simplices in its Grassmannian embedding, with Plücker divisor $H$. The $VPS(Q, n)$ has degree

$$H^m = \sum_{\lambda \vdash m} \binom{m}{\lambda}/(\lambda!) \cdot d_{\lambda}$$

where the sum runs over all partitions $\lambda = (\lambda_1, \ldots, \lambda_n)$ of $m = \binom{n}{2} = \dim VPS(Q, n)$ into integers $n - 1 \geq \lambda_1 \geq \ldots \geq \lambda_n \geq 0$. Here $\lambda^* = (\lambda_1^*, \ldots, \lambda_{n-1}^*)$ denotes the sequence $\lambda_i^* = |\{ j \mid \lambda_j = i \}|$ and $\lambda^! = \prod \lambda_i^!$. Finally

$$d_{\lambda} = \prod_{1 \leq i < j \leq n} (D_i + D_j)$$

is the intersection number of $m$ divisors on the product

$$\mathbf{P}^{n-1-\lambda_1} \times \cdots \times \mathbf{P}^{n-1-\lambda_n}$$

with $D_i$ the pullback of the hyperplane class on the $i$th component.

**Proof.** We first show that for $\binom{n}{2}$ general hyperplanes $h_i \subset \mathbf{P}(T_1)$, the corresponding Plücker divisors $H_{h_i}$ has a proper transverse intersection on the smooth part of $VPS(Q, n)$. Therefore, by properness, the intersection is finite, and, by transversality, it is smooth, so it is a finite set of points. The cardinality is the degree of $VPS(Q, n)$.

First, let $\lambda = (\lambda_1, \ldots, \lambda_n)$ be a partition of $m$ and consider the partition $h_{11}, \ldots, h_{1\lambda_1}, \ldots, h_{n1}, \ldots, h_{n\lambda_n}$ of $m$ general hyperplanes into $n$ sets of size $\lambda_1, \ldots, \lambda_n$. Let $L_i = \cap_j h_{ij}$, it is a linear space of dimension $n - 1 - \lambda_i$. Consider the product of these linear spaces in the product $\mathbf{P}(T_1)^n$:

$$L_1 \times \cdots \times L_n \subset \mathbf{P}(T_1) \times \cdots \times \mathbf{P}(T_1).$$

Let $\Delta \in \mathbf{P}(T_1)^n$ be the union of all diagonals and let $L^\circ = L_1 \times \cdots \times L_n \setminus \Delta \subset \mathbf{P}(T_1)^n$. Then $L^\circ$ parameterizes $n$-tuples of points $\Gamma = \{p_1, \ldots, p_n\} \subset \mathbf{P}(T_1)$, with $p_i \in L_i$. Of course, $L^\circ$ has a natural map to the Hilbert scheme of $\mathbf{P}(T_1)$ that forgets the ordering, so we will identify elements in $L^\circ$ with their image in the Hilbert scheme.

Consider the incidence between subschemes $\Gamma \in L^\circ$ and quadratic forms $q \in T_2$:

$$I_L = \{ (\Gamma, [q]) | I_T \subset q^1 \} \subset L^\circ \times \mathbf{P}(T_2).$$

This variety is defined by the equations $h_{ij}(p_i) = 0$ and the apolarity, $q(I_T) = 0$. Clearly $L$ is a smooth scheme of dimension $\binom{n}{2}$. The fibers of the projection $I_L \rightarrow L$ are $(n - 1)$-dimensional projective spaces, so $I_L$ is a smooth variety of dimension equal to $\dim \mathbf{P}(T_2)$. The projection $I_L \rightarrow \mathbf{P}(T_2)$ is clearly onto, so the fibers are finite. Since both spaces are smooth, the general fiber is smooth. Now, $\Gamma \subset L^\circ$ lies in the fiber over $[q]$, precisely when $I_T \subset q^1$, i.e. $\Gamma \in VPS(Q, n)$ and $h_{ij}(p_i) = 0$, i.e. $\Gamma$ lies in the intersection of all the Plücker hyperplanes $H_{h_{ij}}$. Since the general fibers are smooth the divisors $H_{h_{ij}}$ intersect transversally in $VPS(Q, n)$, where $Q = \{ q = 0 \}$, and have an isolated intersection point at each point $[\Gamma]$. Turning the argument around and
considering all partitions, we get that for general hyperplanes \( h_1, \ldots, h_m \) in \( \mathbf{P}(T_1) \) the Plücker hyperplanes \( H_{h_i} \) has a transversal intersection at a finite number of points in \( VPS(Q, n) \) corresponding to smooth apolar subschemes.

We proceed to compute the cardinality of the intersection, i.e. the formula given in the theorem. Let \( [\Gamma] = \left\{ [p_1, \ldots, p_n] \right\} \in VPS(Q, n) \) be a point in the intersection of the hyperplanes \( H_{h_j} \). Then each \( h_j \) contains some \( p_i \in \Gamma \), by the definition of \( H_{h_j} \). For each \( i \) let \( \lambda_i \) be the number of hyperplanes \( h_j \) that contains \( p_i \). The set of positive integers \( \{\lambda_1, \ldots, \lambda_n\} \) must add up to \( m \):

It is at least \( m \) by definition, and at most \( m \) by the generality assumption discussed above. Therefore the point \([\Gamma]\) defines a unique partition of the set of hyperplanes \( \{h_j\}_{j=1}^m \) into subsets \( \{h_{i j}\}_{j=1}^m \) of cardinality \( \lambda_i \), as above.

The factor \( \binom{m}{\lambda} \) in the degree formula counts the number of ordered partitions of \( m \) hyperplanes into subsets of cardinality \( \lambda_i \), while \( \lambda! \) counts the permutations of the subsets of the same cardinality, i.e. the number of ordered partitions determined by \([\Gamma]\). Therefore the remaining factor \( d_\lambda \) for each partition should count the number of polar simplices \( \Gamma \) that intersect the \( n \) linear subspaces \( L_i = \cap_j h_{i j} \subset \mathbf{P}(T_1) \) of codimension \( \lambda_i \), \( i = 1, \ldots, n \).

Let \( [\Gamma] = \left\{ [p_1, \ldots, p_n] \right\} \in VPS(Q, n) \) and assume that \( (p_1, \ldots, p_n) \in L_1 \times \cdots \times L_n \).

For each pair of linear spaces \( L_i, L_j \) the bilinear form associated to the quadratic form \( q \) restricts to a linear form on the product \( L_i \times L_j \) that vanishes on \( (p_i, p_j) \).

This linear form defines a divisor \( H_{ij} \) in the divisor class \( L_i + L_j \), where \( L_i \) is the pullback to the product of the hyperplane class on \( L_i \). If \( D_{ij} \) and \( D_i \) are the pullbacks of \( H_{ij} \), respectively \( H_i \), to the product \( \Pi_i L_i \), then \( \Gamma \subset \Pi_i L_i \) lies in the intersection \( \cap_{i<j} D_{ij} \).

Conversely, consider a point \( (p_1, \ldots, p_n) \in L_1 \times \cdots \times L_n \) that lies in the intersection of the divisors \( \cap_{i<j} D_{ij} \). The projection of this point into \( \mathbf{P}(T_1) \) is a collection of \( n \) points \( \Gamma = \{ p_1, \ldots, p_n \} \). Let \( p_i = [v_i], v_i \in T_1 \), then the bilinear form \( q : T_1 \times T_1 \to \mathbf{C} \), \( q^{-1}(v_i)(q)(v_j) = 0 \) for every \( i \neq j \), so the hyperplanes \( p_i^\perp \subset \mathbf{P}(S_i) \) form a polar simplex to \( Q \). Hence \([\Gamma]\) is a point in \( VPS(Q, n) \).

Thus \( d_\lambda \) counts the number of polar simplices \( \Gamma \) that intersect the \( n \) linear subspaces \( L_i \) and the degree formula follows.

\( \square \)

The Theorem 1.1 in the introduction follows from Corollary 5.12, Corollary 5.15 and Theorem 6.1. Theorem 1.2 follows from Corollary 2.2, Corollary 5.2, Theorem 6.1 and the degree is computed from Theorem 6.3. Theorem 1.3 follows from Theorem 5.4, Corollary 5.16 and Corollary 2.7.

Communicated by Thomas Peternell

Abstract. According to the Bloch–Beilinson conjectures, an automorphism of a K3 surface $X$ that acts as the identity on the transcendental lattice should act trivially on $\text{CH}^2(X)$. We discuss this conjecture for symplectic involutions and prove it in one third of all cases. The main point is to use special elliptic K3 surfaces and stable maps to produce covering families of elliptic curves on the generic K3 surface that are invariant under the involution.

2010 Mathematics Subject Classification: 14J28 (14J50)

0.1. Let $X$ be a complex projective K3 surface with an automorphism $f : X \to X$. According to the general philosophy of the Bloch–Beilinson conjectures, the induced action of $f$ on the kernel of the cycle map $\text{CH}^*(X) \to H^*(X, \mathbb{Z})$ should be determined by the action of $f$ on the cokernel of the cycle map. More precisely, one expects the following to be true:

Conjecture 0.1. $f^* = \text{id}$ on $\text{CH}^2(X)_0$ if and only if $f^* = \text{id}$ on $T(X)$.

Here, $\text{CH}^2(X)_0 \subset \text{CH}^2(X)$ is the degree zero part, i.e. the kernel of the cycle map $\text{CH}^2(X) \to H^4(X, \mathbb{Z}) \cong \mathbb{Z}$, and $T(X) \subset H^2(X, \mathbb{Z})$ is the transcendental lattice which can be described as the orthogonal complement of the Néron–Severi group $\text{NS}(X) \subset H^2(X, \mathbb{Z})$. Alternatively, $T(X) \subset H^2(X, \mathbb{Z})$ is the smallest sub-Hodge structure such that $H^{2,0}(X) \subset T(X) \otimes \mathbb{C}$. Thus, $f^* = \text{id}$ on $T(X)$ if and only if $f$ acts trivially on $H^{2,0}(X)$. The latter is spanned by the unique (up to scaling) regular two-form $\sigma \in H^{0,2}(X, \Omega^2_X)$, which we think of as a holomorphic symplectic structure. For this reason, an automorphism $f : X \to X$ with $f^* = \text{id}$ on $T(X)$ is called a symplectomorphism.

It is well known that $f^* = \text{id}$ on $\text{CH}^2(X)_0$ implies that $f$ acts trivially on $T(X)$ (see e.g. [16 Ch. 23]). Appropriately rephrased, this holds for arbitrary

\footnote{This work was supported by the SFB/TR 45 ‘Periods, Moduli Spaces and Arithmetic of Algebraic Varieties’ of the DFG (German Research Foundation). The second author is supported by a PhD-scholarship of the Bonn International Graduate School in Mathematics.}
smooth projective varieties and for arbitrary correspondences. It is the converse of the statement that is difficult and that shall be discussed here for symplectic involutions of K3 surfaces, i.e. automorphisms $f$ of order two with $f^*\sigma = \sigma$.

0.2. K3 surfaces $X$ endowed with a symplectic involution $f : X \cong X$ come in families. As shown by van Geemen and Sarti in [4], the moduli space of such $(X, f)$ has one resp. two connected components in each degree $2 d > 0$ depending on the parity of $d$. To be more precise, let $\Lambda_d$ be the lattice $\mathbb{Z} \ell \oplus E_8(-2)$ with $(\ell, \ell) = 2d$ and denote for $d \equiv 0(2)$ by $\tilde{\Lambda}_d$ the unique even lattice containing $\Lambda_d$ with $\tilde{\Lambda}_d/\Lambda_2 \cong \mathbb{Z}/2\mathbb{Z}$ and such that $E_8(-2) \subset \tilde{\Lambda}_d$ is primitive (see [4, Prop. 2.2]).

Then for generic $(X, f)$ one has $\text{NS}(X) \cong \Lambda_d$ or $\text{NS}(X) \cong \tilde{\Lambda}_d$. The class $\ell$ corresponds under this isomorphism to an ample line bundle $L$ on $X$ which spans the $f$-invariant part of $\text{NS}(X)$. If $(X, f)$ is not generic, then one still finds $\Lambda_d$ or $\tilde{\Lambda}_d$ as a primitive sublattice in $\text{NS}(X)$ with $E_8(-2)$ as the orthogonal complement of the invariant part. Conversely, by the Global Torelli theorem any $X$ parametrized by the (non-empty and in fact 11-dimensional) connected moduli spaces $\mathcal{M}_{\Lambda_d}$ or $\mathcal{M}_{\tilde{\Lambda}_d}$ of $\Lambda_d$ resp. $\tilde{\Lambda}_d$-lattice polarized K3 surfaces comes with a symplectic involution $f$ that is determined by its action $= -\text{id}$ on $E_8(-2)$ and $= \text{id}$ on its orthogonal complement.

In other words, for each $d \equiv 1(2)$ the moduli space of K3 surfaces $X$ with a symplectic involution $f$ and an invariant polarization of degree $2d$ has one connected component $\mathcal{M}_{\Lambda_d}$, whereas for $d \equiv 0(2)$ it has two connected components, $\mathcal{M}_{\Lambda_d}$ and $\mathcal{M}_{\tilde{\Lambda}_d}$. Thus the following theorem, the main result of the present paper, proves Conjecture 0.1 in one third of all possible cases.

**Theorem 0.2.** Let $d \equiv 0(2)$ and $(X, f) \in \mathcal{M}_{\tilde{\Lambda}_d}$. Then $f^* = \text{id}$ on $\text{CH}^2(X)$.

0.3. For $d = 1$ (double covers of $\mathbb{P}^2$) and $d = 2$ (quartics in $\mathbb{P}^3$) the conjecture is known to hold, see [2, 14, 15]. For $d = 3$ (complete intersection of a cubic and a quadric in $\mathbb{P}^4$) an interesting approach is outlined in [9]. Theorem 3.2 in [17] proves the conjecture for equivariant complete intersections in varieties with trivial Chow groups.

In [7] the conjecture has been proven for $(X, f)$ in dense subsets of $\mathcal{M}_{\Lambda_d}$ and $\mathcal{M}_{\tilde{\Lambda}_d}$. The proof there relies on Fourier–Mukai equivalences of the bounded derived category of coherent sheaves on $X$ and it is not clear how to push the techniques further to cover generic and hence arbitrary $(X, f)$. The techniques to prove Theorem 0.2 can be applied to symplectic automorphisms $f : X \cong X$ of order $> 2$. If the order of $f$ is a prime $p$, then $p = 2, 3, 5,$ or 7 (cf. [13]), and the results of [1] have in [3] been successfully generalized to cover also the cases $p = 3, 5,$ and 7. Our methods prove Conjecture 0.1 for many components of the moduli space of $(X, f)$ in these cases too, see Section 5.
Theorem 0.3. For $p = 3, 5, \text{ or } 7$ and $d = ep$, there exists one component of the moduli space of polarized K3 surfaces $(X, L)$ with a symplectic automorphism $f : X \to X$ of order $p$ and $L^2 = 2d$ such that Conjecture 0.1 holds true.

0.4. The proof of Theorem 0.2 neither uses derived categories as in [7] nor any deep cycle arguments as e.g. in [6]. As we shall explain in Section 1, it is enough to find a dominating family of integral genus one curves on $X$ that are invariant under $f$ and avoid the fixed points of $f$. The conjecture is then deduced from the absence of torsion in $\text{CH}^2(X)$. It is not clear whether the existence of such a family should be expected in general, but it will be shown here for generic K3 surfaces parametrized by points in $\mathfrak{M}_{\Lambda}$. This is done in two steps. Firstly, we construct a family of genus one (reducible) curves on a particular elliptic K3 surface for which $f$ is given by translation by a two-torsion section, see Section 3. Then, the theory of stable maps is applied to obtain the desired family for generic $X$.

The missing piece to prove Conjecture 0.1 in full generality, or at least for symplectic involutions, is the lack of special K3 surfaces in $\mathfrak{M}_{\Lambda}$ for which appropriate families of genus one curves can be described explicitly.

Acknowledgments: We thank Richard Thomas for a useful discussion concerning Section 2.

Addendum: The results of this article have meanwhile been improved by C. Voisin and the first author. In [18] Voisin replaces singular elliptic curves in the quotient $X/(f)$ and their étale cover in $X$, as used in this paper, by smooth ample curves of high genus. A dimension estimate for the corresponding Prym variety yields finite dimensionality of the anti-invariant part of the Chow group and eventually $f^* = \text{id}$ on $\text{CH}^2(X)$ for symplectic involutions. In particular, neither degeneration to special elliptic K3 surfaces nor the deformation theory of stable maps, which we believe to be of independent interest, enter her arguments. In [8] we use instead arguments involving the derived category $D^b(\text{Coh}(X))$ and lattice theory as developed in [7] to prove the result for symplectic automorphisms of prime order $p \neq 2$. Both results taken together prove $f^* = \text{id}$ on $\text{CH}^2(X)$ for symplectic automorphisms of arbitrary finite order.

1. Covering families of elliptic curves

Let $f : X \to X$ be a symplectic automorphism of finite order and denote its quotient by $\bar{X} := X/(f)$, which is a singular K3 surface. If $f$ has prime order $p$, then $p = 2, 3, 5, \text{ or } 7$ (see [13]). In order to prove Conjecture 0.1 for symplectic automorphisms of finite order (and we do not have anything to say for automorphisms of infinite order), one can restrict to those. The number of fixed points of $f$, all isolated, can be determined by the Lefschetz fixed point formula. E.g. for a symplectic involution, i.e. $p = 2$, there are exactly eight fixed points.

In the following, a family $\mathcal{C}_t \subset X$ of curves given by $\mathcal{C} \subset S \times X$ is called dominating if the projection $\mathcal{C} \to X$ is dominant, i.e. if the curves $\mathcal{C}_t$ parametrized by the closed point $t \in S$ cover a Zariski open subset of $X$. 
Proposition 1.1. Let \( f : X \rightarrow X \) be a symplectic automorphism. Assume there exists a dominating family of integral \( f \)-invariant curves \( C \subset X \) of geometric genus one with \( C_t \cap \text{Fix}(f) = \emptyset \) for generic \( t \). Then \( f^* = \text{id} \) on \( \text{CH}^2(X) \).

Proof. It suffices to prove that for generic \( x \in X \) the points \( x \) and \( y := f(x) \) are rationally equivalent, i.e. \( [x] = [y] \) in \( \text{CH}^2(X) \). Since by Roitman’s theorem \( \text{CH}^2(X) \) is torsion free (see e.g. [10, Ch. 22]), the latter is equivalent to \( [x] = [y] \) being torsion. For any morphism \( g : C \rightarrow X \) from a smooth irreducible curve \( C \) the induced \( g_* : \text{Pic}(C) = \text{CH}^1(C) \rightarrow \text{CH}^2(X) \) is a group homomorphism. Thus, if there exist lifts \( \tilde{x}, \tilde{y} \in C \) of \( x \) resp. \( y \) such that \( O(\tilde{x} - \tilde{y}) \in \text{Pic}^0(C) \) is a torsion line bundle, then automatically \( [x] = [y] \) in \( \text{CH}^2(X) \).

By assumption, a generic closed point \( x \in X \) lies on one of the curves \( C_t \). Since the curves \( C_t \) are assumed to be \( f \)-invariant, \( y = f(x) \) is contained in the same curve and \( f \) lifts to an automorphism \( \tilde{f} \) of the normalization \( C := \tilde{C}_t \), which is a smooth integral curve of genus one. As \( C_t \) avoids the fixed points of \( f \), the automorphism \( \tilde{f} : C \rightarrow C \) is fixed point free and hence \( D := C/\langle \tilde{f} \rangle \) is also smooth of genus one. After choosing origins for \( C \) and \( D \) appropriately, \( C \rightarrow D \) is a morphism of elliptic curves which can be viewed as a quotient of \( C \) by a finite subgroup \( \Gamma \subset C \cong \text{Pic}^0(C) \). Hence points in the same fibre of \( C \rightarrow D \) differ by elements of \( \Gamma \). In particular, \( O_C(\tilde{x} - \tilde{y}) \in \Gamma \subset \text{Pic}^0(C) \) is a torsion line bundle. \( \square \)

The problem now becomes to construct a family of genus one curves as required. We do not know how to do this directly. On the special elliptic surface considered in Section 3 a family of genus one curves is constructed, but the curves are not integral. They become integral only after deformations to the generic case.

2. Stable maps to K3 surfaces

Let \( X \rightarrow S \) be an irreducible family of K3 surfaces with a global line bundle \( \mathcal{L} \). Consider the moduli stack \( \mathcal{M}_g(X, \mathcal{L}) \rightarrow S \) of stable maps \( h : D \rightarrow X_t \) to fibres of \( X \rightarrow S \) such that \( D \) is of arithmetic genus \( g \) with \( h_* (D) \in |\mathcal{L}| \). As the stack structure of \( \mathcal{M}_g(X, \mathcal{L}) \) is of no importance to us, we shall ignore it and treat \( \mathcal{M}_g(X, \mathcal{L}) \) as a moduli space. If we do not want to fix the linear equivalence class of the image curves, we will simply write \( \mathcal{M}_g(X) \).

The following fact has been used in various contexts in the literature, but mostly for \( g = 0 \) (see e.g. [11, 12]). We shall need the following statement for \( g = 1 \).

Proposition 2.1. Every irreducible component of \( \mathcal{M}_g(X, \mathcal{L}) \) is of dimension at least \( g + \dim(S) \).

Proof. The starting point is [10, Thm. 2.17]: For simplicity let \( \pi : X \rightarrow S \) be a smooth projective family over an irreducible base \( S \) and let \( \mathcal{D} \rightarrow S \) be a flat and projective family of curves. Every irreducible component of \( \text{Mor}_S(D, X) \)
containing a morphism \( h : D := D_0 \to X := X_0 \) is of dimension at least
\[
\chi(D, h^* T_X) + \dim(S).
\]

The first term \( \chi(D, h^* T_X) = h^0(D, h^* T_X) - h^1(D, h^* T_X) \) reflects the usual deformation-obstruction theory for the morphism \( h : D \to X \). A priori, the obstructions to deforming the morphism \( h : D \to X \) are contained in \( H^1(D, h^* T_X) \), which is part of an exact sequence
\[
\ldots \to H^1(D, h^* T_X) \to H^1(D, h^* T_X) \to H^1(D, h^* \pi^* T_S) \to 0.
\]

Since the morphism \( D \to X \subset X \to S \) is constant, there are no obstructions to deforming it sideways at least when \( S \) is smooth. In other words, the obstructions to deforming \( h : D \to X \) are contained in the image of \( H^1(D, h^* T_X) \) which leads to the stronger bound in (1).

A similar argument allows one to treat the case of varying domain \( D \). The usual obstruction theory for stable maps shows that \( M_g(X, L) \) is of dimension at least \( \chi(D, (h^* \Omega_X \to \Omega_D)^*) \), where the two term complex \( h^* \Omega_X \to \Omega_D \) is concentrated in degree \(-1\) and \( 0 \), see \([5]\). For \( X = X_0 \) in a family \( X \to S \), the analogue of (1) then says that \( M_g(X) \) in a point corresponding to a stable map \( h : D \to X \) is of dimension at least
\[
\chi(D, (h^* \Omega_X \to \Omega_D)^*) + \dim(S) = g - 1 + \dim(S).
\]

The last equation follows from a standard Riemann–Roch calculation.

The remaining issue is to increase the bound by restricting to families \( X \to S \) which come with a deformation \( L \) of \( L := O(h_*(D)) \). One can either invoke reduced deformation theory for K3 surfaces as developed recently in \([11]\) or use the following trick.

Any given family \( (X, L) \to S \) with a polarization \( L \) can be thickened to a family \( \tilde{X} \to \tilde{S} \) with \( \dim \tilde{S} = \dim S + 1 \) such that transversally to \( S \subset \tilde{S} \) the line bundle \( L \) is obstructed (even to first order). More precisely, for \( t \in S \) the line bundle \( L_t \) on \( X_t \) deforms to first order in the direction of \( v \in T_{\tilde{S}, t} \), if and only if \( v \in T_{\tilde{S}, t} \subset T_{\tilde{S}, t} \). If \( L \) is fibrewise ample, then the thickening \( \tilde{X} \to \tilde{S} \) can be explicitly described by using the twistor space construction for each fibre \( X_t \) and the Kähler class given by \( c_1(L_t) \). (Note that in particular, \( \tilde{X} \to \tilde{S} \) will in general not be projective.) Otherwise, one uses the standard deformation theory of K3 surfaces to produce such a family at least locally, which is enough for the following dimension count.

By the discussion above, \( M_g(\tilde{X}) \) is in \([h : D \to X]\) of dimension
\[
g - 1 + \dim(\tilde{S}) = g + \dim(S).
\]

On the other hand, \( h : D \to X \) cannot deform sideways in a tangent direction \( v \in T_{\tilde{S}, 0} \) that is not contained in \( T_{\tilde{S}, 0} \), because \( O(h_*(D)) = L_0 \). This shows that the two moduli spaces \( M_g(\tilde{X}) \) and \( M_g(\tilde{X}) \) coincide near the point given by \([h : D \to X]\). \( \square \)
Suppose the fibre $\mathcal{M}_0$ of an irreducible component $\mathcal{M} \subset \mathcal{M}_g(X, \mathcal{L})$ is of dimension $\leq g$ for some $0 \in S$. Then $\mathcal{M}$ dominates $S$. \hfill \square

In other words, if the moduli space $\mathcal{M}_g(X_0, \mathcal{L}_0)$ of stable maps to one fibre $X_0$ has the expected dimension $g$ in $[h : D \rightarrow X_0]$, then $h$ can be deformed to a stable map $h_2 : D_2 \rightarrow X_2$ to the generic fibre. To ensure that the condition is met, we shall later use the following criterion, c.f. [9, Cor. 1.2.5] and [12, Lem. 2.6].

**Proposition 2.3.** Suppose the stable map $h : D \rightarrow X$ satisfies the following conditions:

i) If $D_1, D_2, \ldots, D_n$ are the components of $D$, then $D_2, \ldots, D_n$ are smooth and rational.

ii) The first component $D_1$ is smooth of genus $g$ and $h|_{D_1} : D_1 \rightarrow X$ is an embedding.

iii) The morphism $h$ is unramified.

iv) Two components $D_i$ and $D_j$ intersect transversally in one point if $|i - j| = 1$ and not at all otherwise.

Then $\mathcal{M}_g(X)$ is of dimension $g$ in $[h : D \rightarrow X]$.

**Proof.** We copy the argument from [11, Lem. 2.7]. First of all, since $h$ is unramified, the complex $h^*\Omega_X \rightarrow \Omega_D$ is a locally free sheaf of rank one concentrated in degree $-1$, the dual of which is denoted $N_h$. Then, one proceeds by induction over $n$ and uses the exact sequence

$$0 \rightarrow N_h(-x)|_{D'} \rightarrow N_h \rightarrow N_h|_{D_n} \rightarrow 0,$$

where $D' := D_2 \cup \ldots \cup D_{n-1}$ and $\{x\} = D_{n-1} \cap D_n$. From the exact sequence

$$0 \rightarrow N_h|_{D_n} \rightarrow h^*\Omega_X|_{D_n} \rightarrow \Omega_D|_{D_n} \rightarrow 0$$

and $\Omega_D|_{D_n} \cong \mathcal{O}(-1)$, one deduces $N_h|_{D_n} \cong \mathcal{O}(-1)$. Thus, $H^i(N_h) \cong H^i(N_h(-x)|_{D'})$. On the other hand, $N_h(-x)|_{D'} = N_{h'}$, where $h' := h|_{D'} : D' \rightarrow X$. By induction this eventually yields $H^i(N_h) \cong H^i(N_{D_1/X})$. But clearly, $h^0(N_{D_1/X}) = h^0(D_1, \omega_{D_1}) = g$ and the deformations of $D_i \subset X$ are unobstructed. \hfill \square

**Remark 2.4.** Maybe more geometrically, the arguments show that deformations of $h : D \rightarrow X$ are all given by deforming $D_1 \subset X$.

**3. Special elliptic surfaces**

We follow [11, Sect. 4] for the construction of an elliptic K3 surface $X \rightarrow \mathbb{P}^1$ with a symplectic involution given by a two-torsion section. Deformations of $X$ will lead to K3 surfaces with Néron–Severi group $\tilde{\Lambda}_{2d}$ with $d = 2e > 2$.

The elliptic K3 surface $X \rightarrow \mathbb{P}^1$ is described by an equation of the form

$$y^2 = x(x^2 + a(t)x + b(t))$$

with general $a(t)$ and $b(t)$ of degree 4 resp. 8. Then the fibration has two obvious sections: The section at infinity $\sigma$ given by $x = z = 0$, which will serve...
us as the zero section, and a disjoint section \( \tau \) given by \( x = y = 0 \). Using the explicit equation, one finds that \( \tau \) has order two. Thus, translation by \( \tau \) defines an involution \( f : X \to X \) which is symplectic. Still following [4], one computes the singular fibres of \( X \to \mathbb{P}^1 \): There are eight fibres of type \( I_1 \) (a rational curve with one node) and eight fibres of type \( I_2 \) (the union of two copies of \( \mathbb{P}^1 \) intersecting transversally in two points). They can be found over the zeroes of \( b \in H^0(\mathbb{P}^1, \mathcal{O}(8)) \) resp. \( a^2 - 4b \in H^0(\mathbb{P}^1, \mathcal{O}(8)) \). The fixed points of \( f \) are the nodes of the eight \( I_1 \)-fibres which are all avoided by \( \sigma \) and \( \tau \). Moreover, \( f \) interchanges the two components of each \( I_2 \)-fibre.

The components of the \( I_2 \)-fibres not meeting \( \sigma \) are denoted \( N_1, \ldots, N_8 \). Then \( \hat{N} = (1/2) \sum N_i \in \text{NS}(X) \). Moreover, if \( F \) denotes the class of a generic fibre (and by abuse also a generic fibre itself), then \( \sigma \) and \( F \) span a hyperbolic plane and \( \tau = \sigma + 2F - \hat{N} \). The Néron–Severi group of \( X \) (for general \( a \) and \( b \)) is thus \( \langle \sigma, F \rangle \oplus \langle N_1, \ldots, N_8, \hat{N} \rangle \), which is of rank 10. Next consider a curve of the form \( C = eN + F + \sigma + \tau \), where \( N \) is one of the \( I_2 \)-fibres, and let \( L := \mathcal{O}(C) \). Then \( L \) is big and nef. Indeed, \( (L.L) = 4e > 0 \) and \( C \) intersects all its irreducible components positively, e.g. \( (C.\sigma) = e - 1 > 0 \). In fact, \( L \) is ample as it clearly intersects all horizontal curves positively and has also positive intersection with all \((-2)\)-curves (e.g. the two components of the \( I_2 \)-fibres). Moreover, \( L \) is primitive, as \( (C.N_i) = 1 \). Since \( f \) respects the fibration and interchanges \( \sigma \) and \( \tau \), the curve \( C \) is \( f \)-invariant and disjoint from \( \text{Fix}(f) \).

Let us now consider the quotient \( \tilde{X} := X/\langle f \rangle \) which is a singular K3 surface with eight ordinary double points. Its minimal resolution \( Y \to \tilde{X} \) comes with a natural elliptic fibration \( Y \to \mathbb{P}^1 \). Note that the fibres of type \( I_1 \) and \( I_2 \) are interchanged when passing from \( X \) to \( Y \).
The quotient $\overline{C} := C / \langle f \rangle \subset \overline{X}$ avoids the singular locus of $\overline{X}$ and thus can also be viewed as a curve in $Y$. For the same reason, the line bundle $L$ descends to an ample line bundle $\overline{L}$ on $\overline{Y}$. Note that $\overline{C}$ decomposes as $\overline{C} = e \overline{N} + \overline{F} + \overline{\sigma}$, where $\overline{N}$ is an $I_1$-fibre of $Y \dashrightarrow \mathbb{P}^1$, $\overline{F}$ is a smooth fibre, and $\overline{\sigma}$ is a section.

**Lemma 3.1.** There exists a stable map $h : D \rightarrow \overline{X}$ of arithmetic genus one with image $\overline{C}$ and such that $\mathcal{M}_1(\overline{X}, \overline{L})$ is one-dimensional in $h$.

**Proof.** Since $\overline{C}$ avoids the singularities of $\overline{X}$, we can equally work with $\overline{C} \subset Y$. The curve $D$ shall have components $D_1, D_2, \ldots, D_n$, $n = e + 2$, with $D_1 \rightarrow \overline{F}$, $D_2 \rightarrow \overline{\sigma}$, and $D_i \rightarrow \overline{N}$, $i \geq 2$, being the normalization. The gluing is defined according to the picture (cf. [1, 9, 12]):

Obviously, $D$ is of arithmetic genus one and $h_*(D) = \overline{C}$. Moreover, the assumptions of Proposition 2.3 are satisfied and hence $\mathcal{M}_1(Y)$ is of dimension one in $[h : D \rightarrow Y]$. □

Now consider a generic deformation

\[
(\mathcal{X}, \mathcal{L}) \rightarrow S
\]

of $(X, L, f)$, i.e. $(\mathcal{X}_0, f_0) = (X, f)$ for a distinguished $0 \in S$ and for generic $t \in S$ the fibre $\text{NS}(\mathcal{X}_t)$ has rank $\rho = 9$ with $f_t$-invariant part spanned by $\mathcal{L}_t$. Taking quotients, one obtains a family of singular K3 surfaces $\mathcal{X} \rightarrow S$. Clearly, $L = \mathcal{O}(C)$ descends to the quotient $\overline{X}$, for $C$ is $f$-invariant and avoids the fixed points. Hence the line bundle $\mathcal{L}$ also descends to a relatively ample line bundle $\overline{\mathcal{L}}$. (The obstructions to deforming $L$ resp. $\mathcal{L}$ sideways are the same.) Note that for generic $t \in S$ the line bundle $\overline{\mathcal{L}}_t$ generates $\text{Pic}(\mathcal{X}_t)$.

Let us apply the discussion of Section 2 to $h : D \rightarrow \mathcal{X}_0 = \overline{X}$. So, consider the relative moduli space of stable maps of genus one $\mathcal{M}_1(\mathcal{X}, \mathcal{L}) \rightarrow S$.  

**Documenta Mathematica 18 (2013) 507–517**
Corollary 3.2. The stable map $h : D \to X$ thus constructed deforms sideways to stable maps $h_t : D_t \to \mathcal{X}_t$. Moreover, for generic $t \in S$ the curve $h_{t*}(D_t) \subset \mathcal{X}_t$ and its preimage in $\mathcal{X}_t$ are integral and disjoint from the singular locus resp. the fixed point set of $f_t$.

Proof. The existence of the deformation to the nearby fibres follows directly from Proposition 2.3 and Corollary 2.2. Since $C = h_*(D)$ avoids the singularities of $X$, this will hold for generic $t$. Clearly, $h_{t*}(D_t) \in |\mathcal{L}_t|$. Therefore, since $\mathcal{L}_t$ generates the invariant part of $\text{NS}(\mathcal{X}_t)$ and hence $\mathcal{L}_t$ generates NS$(\mathcal{X}_t)$, the curve $h_{t*}(D_t)$ must be integral. Suppose the preimage $C_t$ of $h_{t*}(D_t)$ were not integral for $t$ generic, i.e. $C_t = C_t' + C_t''$ with $f_t(C_t') = C_t''$. (Use that $f_t$ is an involution.) The two components would then specialize to $C'$ resp. $C''$ on $X$ with $C = C' + C''$ and $f(C') = C''$. We may assume that $F \subset C'$. But then also $F = f(F) \subset f(C') = C''$ which eventually yields the contradiction that $F$ appears with multiplicity at least two in $C$.

Remark 3.3. In fact, since the stable map $h : D \to X$ deforms with the fibre component $F$ in a one-dimensional family, also the deformations $h_t : D_t \to \mathcal{X}_t$ come in a family dominating $\mathcal{X}_t$. Thus, one obtains a dominating family of integral genus one curves in the generic deformation $\mathcal{X}_t$ that are $f_t$-invariant and avoid the fixed points of $f_t$.

4. Proof of the main theorem

The outcome of the above construction are generic K3 surfaces $\mathcal{X}_t \in \mathcal{M}_d$ with a symplectic involution $f_t$ such that $\mathcal{X}_t = \mathcal{X}_t/(f_t)$ contains a one-dimensional family of integral curves of geometric genus one that avoid the singular locus. This immediately leads to a proof of our main result.

Theorem 4.1. For all $(X, f) \in \mathcal{M}_d$, the symplectic involution $f : X \to X$ acts as id on $\text{CH}^2(X)$.

Proof. The case $d = 2$ follows from [14]. So we assume $d = 2e > 2$, i.e. $e > 1$. We first show that the above discussion combined with Proposition 1.1 proves the assertion for generic $(X, f) \in \mathcal{M}_d$. Consider a deformation $\mathcal{X}_t$ of the special elliptic K3 surface $\mathcal{X}$. Then for generic $t \in S$ one has $\text{NS}(\mathcal{X}_t) = \tilde{\Lambda}_d$. Indeed, by [4] Prop. 2.7 only in this case do all $f_t$-invariant line bundles actually descend to the quotient $\tilde{\mathcal{X}}_t$. Hence the elliptic K3 surfaces described by (3) can be connected to the generic K3 surface parameterized by $\mathcal{M}_d$. Here we use that $\mathcal{M}_d$ is connected.

The generic fibre of the family $\mathcal{X}_t$ satisfies the assumption of Proposition 1.1. Indeed, by Corollary 3.2 and Remark 3.3 there exists a dominating family of integral curves of arithmetic genus one on the generic fibre $\mathcal{X}_t$ that are invariant under the involution and avoid the fixed points.

Now consider an arbitrary $(X, f) \in \mathcal{M}_d$. Then any $x \in X$ can be viewed as a specialization of points $x_t$ in generic deformations $(\mathcal{X}_t, f_t) \in \mathcal{M}_d$. Clearly, the
points $f_t(x_t)$ then specialize to $f(x)$. For generic $X_t$ we have already shown $[x_t] = [f_t(x_t)]$ in $\text{CH}^2(X_t)$ and thus specialization yields $[x] = [f(x)]$ in $\text{CH}^2(X)$ for all $x \in X$. □

5. Further comments

We briefly outline how to adapt our techniques to the case of symplectic automorphisms of prime order. For $p = 3, 5,$ and $7$, Garbagnati and Sarti describe in [3] Thm. 4.1 lattices $\Omega_p$ of rank 12, 16, resp. 18 that are isomorphic to the anti-invariant part of $f^*$ acting on $H^2(X, \mathbb{Z})$. Similar to the case $p = 2$, the generic polarized K3 surface $(X, L)$ of degree 2$d$ with a symplectic automorphism $f : X \sim X$ of order $p$ leaving $L$ fixed has Picard group isomorphic to $\Lambda_{p,d} := \mathbb{Z}L \oplus \Omega_p$ or possibly, if $d \equiv 0(p)$, isomorphic to a lattice $\tilde{\Lambda}_{p,d}$ that contains $\Lambda_{p,d}$ as a primitive sublattice of index $p$. In fact, the case $\Lambda_{7,d}$ is not realized if $d \equiv 0(7)$ (cf. [3] Prop. 5.2), but unfortunately it is not known whether the lattices $\tilde{\Lambda}_{p,d}$ are unique for given $p$ and $d \equiv 0(p)$ (see [3] Sec. 6). The moduli spaces are of dimension 7, 3, resp. 1.

Examples of symplectic automorphisms of order 3, 5, and 7 have been described in [3] Sec. 3.1. They are again given by translation by a torsion section. The Picard numbers in these examples are 14, 18, resp. 20 and in each case they correspond to points in (at least) one component of the moduli space of polarized K3 surfaces $(X, L)$ with a symplectic automorphism $f$ of degree $L^2 = 2d$. This leads to the following result:

**Theorem 5.1**. For $p = 3, 5,$ or $7$ and $d \equiv 0(p)$, there exists one component of the moduli space of polarized K3 surfaces $(X, L)$ with a symplectic automorphism $f : X \sim X$ of order $p$ and $L^2 = 2d$ such that Conjecture [11] holds true. □

It is very likely that for $p = 7$ and $d \equiv 0(7)$ the result can be strengthened to cover all K3 surfaces, as we would expect that $\tilde{\Lambda}_{7,d}$ is in fact unique.

Integration of Vector Fields on Smooth and Holomorphic Supermanifolds

Stéphane Garnier and Tilmann Wurzbacher

Received: September 19, 2012
Revised: December 12, 2012
Communicated by Christian Bär

Abstract. We give a new and self-contained proof of the existence and unicity of the flow for an arbitrary (not necessarily homogeneous) smooth vector field on a real supermanifold, and extend these results to the case of holomorphic vector fields on complex supermanifolds. Furthermore we discuss local actions associated to super vector fields, and give several examples and applications, as, e.g., the construction of an exponential morphism for an arbitrary finite-dimensional Lie supergroup.

2010 Mathematics Subject Classification: Primary 58A50, 37C10; Secondary 57S20, 32C11
Keywords and Phrases: Supermanifolds; Vector fields; Flows; Group actions

1 Introduction

The natural problem of integrating vector fields to obtain appropriate “flow maps” on supermanifolds is considered in many articles and monographs (compare, e.g., \cite{17}, \cite{2}, \cite{19}, \cite{14} and \cite{3}) but a “general answer” was to our knowledge only given in the work of J. Monterde and co-workers (see \cite{12} and \cite{13}). Let us consider a supermanifold $\mathcal{M} = (\mathcal{M}, \mathcal{O}_\mathcal{M})$ together with a vector field $X$ in $\mathcal{T}_\mathcal{M}(\mathcal{M})$, and an initial condition $\phi$ in $\text{Mor}(\mathcal{S}, \mathcal{M})$, where $\mathcal{S} = (\mathcal{S}, \mathcal{O}_\mathcal{S})$ is an arbitrary supermanifold and $\text{Mor}(\mathcal{S}, \mathcal{M})$ denotes the set of morphisms from $\mathcal{S}$ to $\mathcal{M}$. The case of classical, ungraded, manifolds leads one to consider the following question: does there exist a “flow map” $F$ defined on an open sub supermanifold $\mathcal{V} \subset \mathbb{R}^{1|1} \times \mathcal{S}$ and having values in $\mathcal{M}$ and an appropriate
derivation on $\mathbb{R}^{1|1}$, $D = \partial_t + \partial_\tau + \tau(a\partial_t + b\partial_\tau)$, where $\partial_t = \frac{\partial}{\partial t}$, $\partial_\tau = \frac{\partial}{\partial \tau}$ and $a$, $b$ are real numbers, such that the following equations are fulfilled

$$D \circ F^* = F^* \circ X$$
$$F \circ \text{inj}_{V(0) \times S}^V = \phi.$$  \hspace{1cm} (1)

Of course, $V$ should be a “flow domain”, i.e. an open sub supermanifold of $\mathbb{R}^{1|1} \times S$ such that $\{0\} \times S$ is contained in the body $V$ of $\mathcal{V}$ and for $x$ in $S$, the set $I_x \subset \mathbb{R}$ defined by $I_x \times \{x\} = (\mathbb{R} \times \{x\}) \cap V$ is an open interval. Furthermore $\text{inj}_{V(0) \times S}^V$ denotes the natural injection morphism of the closed sub supermanifold $\{0\} \times S$ of $\mathcal{V}$ into $\mathcal{V}$. Of course, we could concentrate on the case $S = M$ and $\phi = \text{id}_M$, but it will be useful for our later arguments to state all results in this (formally) more general setting.

Though for homogeneous vector fields ($X = X_0$ or $X = X_1$) system (11) does always have a solution, in the general case ($X = X_0 + X_1$ with $X_0 \neq 0$ and $X_1 \neq 0$) the system is overdetermined. A simple example of an inhomogeneous vector field such that (11) is not solvable is given by $X = X_0 + X_1 = \left(\frac{\partial}{\partial x} + \xi \frac{\partial}{\partial \xi}\right) + \left(\frac{\partial}{\partial \xi} + \xi \frac{\partial}{\partial x}\right)$ on $\mathcal{M} = \mathbb{R}^{1|1}$. The crucial novelty of [13] is to consider instead of (11) the following modified, weakened, problem

$$\left(\text{inj}_{\mathbb{R}^{1|1}}^\mathbb{R}\right)^* \circ D \circ F^* = \left(\text{inj}_{\mathbb{R}^{1|1}}^\mathbb{R}\right)^* \circ F^* \circ X$$
$$F \circ \text{inj}_{V(0) \times S}^V = \phi,$$  \hspace{1cm} (2)

where $\text{inj}_{\mathbb{R}^{1|1}}^\mathbb{R} = \text{inj}_{\mathbb{R}^{1|1} \times S}^\mathbb{R}$ is again the natural injection (and where the above more general derivation $D$ could be replaced by $\partial_t + \partial_\tau$ since $(\text{inj}_{\mathbb{R}^{1|1}}^\mathbb{R})^*$ annihilates germs of superfunctions of the type $\tau \cdot f, f \in \mathcal{O}_{\mathbb{R} \times S}$).

In [13] (making indispensable use of [12]) it is shown that in the smooth case (2) has a unique maximal solution $F$, defined on the flow domain $\mathcal{V} = (V, \mathcal{O}_{\mathbb{R}^{1|1} \times S|V})$, where $V \subset \mathbb{R} \times S$ is the maximal flow domain for the flow of the reduced vector field $\tilde{X} = \tilde{X}_0$ on $\mathcal{M}$ with initial condition $\tilde{\phi}$. Since the results of [12] are obtained by the use of a Batchelor model for $\mathcal{M}$, i.e. a real vector bundle $E \to M$ such that $\mathcal{M} \cong (M, \Gamma^\infty_{\Lambda E})$, and a connection on $E$, we follow here another road, closer to the classical, ungraded, case and also applicable in the case of complex supermanifolds and holomorphic vector fields.

Our new method of integrating smooth vector fields on a supermanifold in Section 2 consists in first locally solving a finite hierarchy of ordinary differential equations, and is here partly inspired by the approach of [3], where the case of homogeneous super vector fields on compact supermanifolds is treated. We then show existence and unicity of solutions of (2) on smooth supermanifolds and easily deduce the results of [13] from our Lemmata 2.1 and 2.2.
A second beautiful result of [13] (more precisely, Theorem 3.6 of that reference) concerns the question if the flow $F$ solving (2) fulfills “flow equations”, as in the ungraded case. Hereby, we mean the existence of a Lie supergroup structure on $\mathbb{R}^{1|1}$ such that $F$ is a local action of $\mathbb{R}^{1|1}$ on $\mathcal{M}$ (in case $S = \mathcal{M}, \phi = id_M$).

Again, the answer is a little bit unexpected: in general, given $X$ and its flow $F : \mathbb{R}^{1|1} \times \mathcal{M} \supset \mathcal{Y} \to \mathcal{M}$, there is no Lie supergroup structure on $\mathbb{R}^{1|1}$ such that $F$ is a local $\mathbb{R}^{1|1}$-action (with regard to this structure). The condition for the existence of such a structure on $\mathbb{R}^{1|1}$ is equivalent to the condition that (2) holds without the post-composition with $(\text{inj}_{\mathbb{R}^{1|1}})^*$, i.e. the overdetermined system (1) is solvable. Furthermore, both conditions cited are equivalent to the condition that $RX_0 \oplus RX_1$ is a sub Lie superalgebra of $\mathcal{T}_M(M)$, the Lie superalgebra of all vector fields on $\mathcal{M}$.

After discussing Lie supergroup structures and right invariant vector fields on $\mathbb{R}^{1|1}$, as well as local Lie group actions in the category of supermanifolds in general, we show in Section 3 the equivalence of the above three conditions, already given in [13]. We include our proof here notably in order to be able to apply it in the holomorphic case in Section 5 (see below) by simply indicating how to adapt it to this context. Let us nevertheless observe that our result is slightly more general since we do not need to ask for any normalization of the supercommutators between $X_1$ and $X_0$ resp. $X_1$, thus giving the criterion some extra flexibility in applications.

In Section 4, we give several examples of vector fields on supermanifolds, homogeneous and inhomogeneous, and explain their integration to flows. Notably, we construct an exponential morphism for an arbitrary finite-dimensional Lie supergroup, via a canonically defined vector field and its flow. We comment here also on the integration of what are usually called “(infinitesimal) supersymmetries” in physics, i.e., purely odd vector fields having non-vanishing self-commutators.

Finally, in Section 5 we adapt our method to obtain flows of vector fields (compare Section 2 and notably Lemma 2.1) to the case of holomorphic vector fields on holomorphic supermanifolds. To avoid monodromy problems one has, of course, to take care of the topology of the flow domains, and maximal flow domains are -as already in the ungraded holomorphic case- no more unique. Otherwise the analogues of all results in Section 2 and 3 continue to hold in the holomorphic setting.

Throughout the whole article we will work in the ringed space-approach to supermanifolds (see, e.g., [9], [10], [11] and [13] for detailed accounts of this approach). Given two supermanifolds $\mathcal{M} = (M, \mathcal{O}_M)$ and $\mathcal{N} = (N, \mathcal{O}_N)$, a “morphism” $\phi = (\tilde{\phi}, \phi^*) : \mathcal{M} \to \mathcal{N}$ is thus given by a continuous map $\tilde{\phi} : M \to N$ between the “bodies” of the two supermanifolds and a sheaf
homomorphism \( \phi^* : \mathcal{O}_N \to \tilde{\phi} \mathcal{O}_M \). The topological space \( M \) comes canonically with a sheaf \( C_M^\infty = \mathcal{O}_M / J \), where \( J \) is the ideal sheaf generated by the germs of odd superfunctions, such that \((M, C_M^\infty)\) is a smooth real manifold. Then \( \tilde{\phi} \) is a smooth map from \((M, C_M^\infty)\) to \((N, C_N^\infty)\). Let us recall that a (super) vector field on \( M = (M, \mathcal{O}_M) \) is, by definition, an element of the Lie superalgebra \( \mathcal{T}_M(M) = (\text{Der}(\mathcal{O}_M))(M) \) and that \( X \) always induces a smooth vector field \( \tilde{X} \) on \((M, C_M^\infty)\). For \( p \in M \) and \( f + J_p \in (C_M^\infty)_p = (\mathcal{O}_M / J)_p \), one defines \( \tilde{X}_p(f + J_p) = X_0(f)(p) \), where \( X_0 \) is the even part of \( X \) and for \( g \in (\mathcal{O}_M)_p \), \( g(p) \in \mathbb{R} \) is the value of \( g \) in the point \( p \) of \( M \).

2 Flow of a vector field on a real supermanifold

In this section we give our main result on the integration of general (i.e. not necessarily homogeneous) vector fields by a new method, avoiding auxiliary choices of Batchelor models and connections, as in [12]. Our more direct approach is inspired, e.g., by [3], where the case of homogeneous vector fields on compact manifolds is treated, and it can be adapted to the holomorphic case (see Section 4).

For the sake of readability we will often use the following shorthand: if \( P \) is a supermanifold, we write \( \text{inj}^{R|1}_R \) for \( \text{inj}^{R|1}_R \times P \). Furthermore, the canonical coordinates of \( R|1 \) will be denoted by \( t \) and \( \tau \), with ensuing vector fields \( \partial_t = \frac{\partial}{\partial t} \) and \( \partial_\tau = \frac{\partial}{\partial \tau} \).

**Lemma 2.1.** Let \( U \subset \mathbb{R}^{m|n} \) and \( W \subset \mathbb{R}^{p|q} \) be superdomains, \( X \in \mathcal{T}_W(W) \) be a super vector field on \( W \) (not necessarily homogeneous) and \( \phi \in \text{Mor}(U, W) \), and \( t_0 \in \mathbb{R} \). Let furthermore \( H : V \to W \) be the maximal flow of \( \tilde{X} \in \mathcal{X}(W) \), i.e. \( \partial_t \circ H^* = H^* \circ \tilde{X} \), subject to the initial condition \( H(t_0, \cdot) = \tilde{\phi} : U \to W \). Let now \( \mathcal{V} \) be \( (V, \mathcal{O}_{U \times V}) \) and \( (t, \tau) \) the canonical coordinates on \( R|1 \), then there exists a unique \( \tilde{F} : V \to W \) such that

\[
\left( \text{inj}^{R|1}_R \right)^* \circ \left( \partial_t + \partial_\tau \right) \circ F^* = \left( \text{inj}^{R|1}_R \right)^* \circ F^* \circ X \quad \text{and} \quad (3)
\]

\[
F \circ \text{inj}^{V}_{\{t_0\} \times U} = \phi. \quad (4)
\]

Moreover, \( \tilde{F} : V \to W \) equals the underlying classical flow map \( H \) of the vector field \( \tilde{X} \) with initial condition \( \phi \).

**Proof.** Let \((u_i) = (x_i, \xi_i)\) and \((w_j) = (y_j, \eta_j)\) denote the canonical coordinates on \( \mathbb{R}^{m|n} \) and \( \mathbb{R}^{p|q} \), respectively. Then there exist smooth functions \( a^j_i \in C^\infty_N(W) \) such that

\[
X = \sum_{j=1}^{p+q} \left( \sum_{j} a^j_i(y) \eta^j \right) \partial_{w_j},
\]

**Documenta Mathematica** 18 (2013) 519–545
where $J = (\beta_1, \ldots, \beta_q)$ runs over the index set $\{0, 1\}^q$ and $\eta^I = \prod_{s=1}^q \eta^\beta_s$. We then have, of course,

$$X_0 = \sum_j \left( \sum_{|J|=|w_j|} a_j^I(y) \eta^I \right) \partial_{w_j} \text{ resp. } X_1 = \sum_j \left( \sum_{|J|=|w_j|+1} a_j^I(y) \eta^I \right) \partial_{w_j}.$$ 

Here, $|J|$ equals $\beta_1 + \cdots + \beta_q \mod 2$ and $|w_j|$ is the parity of the coordinate function $w_j$. The morphism $F$ determines and is uniquely determined by functions $f^I_j, g^I_j \in \mathcal{C}^{\infty}_{R\times R^n}(V)$ fulfilling for each $j \in \{1, \ldots, p+q\}$

$$F^*(w_j) = \sum_{|I|=|w_j|} f^I_j(t, x) \xi^I + \sum_{|I|=|w_j|+1} g^I_j(t, x) \tau \xi^I$$

(and $f^I_j = 0$ if $|I| \neq |w_j|$, $g^I_j = 0$ if $|I| \neq |w_j| + 1$) as is well-known from the standard theory of supermanifolds (compare, e.g., Thm. 4.3.1 in [20]). Here and in the sequel $I = (\alpha_1, \ldots, \alpha_n)$ is an element of the set $\{0, 1\}^n$ and $\xi^I$ stands for the product $\xi^{I_1} \cdot \xi^{I_2} \cdots \xi^{I_n}$. The notation $|I|$ again denotes the parity of $I$, i.e. $|I| = \alpha_1 + \cdots + \alpha_n \mod 2$.

Equation (8) is equivalent to the following equations:

$$\left(\text{inj}_{R}^{R^{[1]}_\mathbb{R}}\right)^* \circ \partial_t \circ F^* = \left(\text{inj}_{R}^{R^{[1]}_\mathbb{R}}\right)^* \circ F^* \circ X_0 \quad (5)$$

$$\left(\text{inj}_{R}^{R^{[1]}_\mathbb{R}}\right)^* \circ \partial_x \circ F^* = \left(\text{inj}_{R}^{R^{[1]}_\mathbb{R}}\right)^* \circ F^* \circ X_1 \quad (6)$$

Applying (3) to the canonical coordinate functions on $W$, we get the following system, which is equivalent to (5):

$$\sum_{|I|=|w_j|} \partial_t f^I_j : \xi^I = \sum_{|J|=|w_j|} \tilde{F}^* (a^I_j) \tilde{F}^* (\eta^J) \text{ for all } j \in \{1, \ldots, p+q\}, \quad (7)$$

and (6) is equivalent to

$$\sum_{|I|=|w_j|+1} g^I_j : \xi^I = \sum_{|J|=|w_j|+1} \tilde{F}^* (a^I_j) \tilde{F}^* (\eta^J) \text{ for all } j \in \{1, \ldots, p+q\}, \quad (8)$$

where $\tilde{F} := F \circ \text{inj}_{R}^{R^{[1]}_\mathbb{R}} : \mathcal{V} := (V, \mathcal{O}_{R\times \ell}(V)) \rightarrow W$. Let us immediately observe that the underlying smooth map of $\tilde{F}$ equals $\tilde{F}$, the smooth map underlying the morphism $F$.

Moreover the initial condition (9) is equivalent to

$$\sum_{|I|=|w_j|} f^I_j(t_0, x) \xi^I = \phi^* (w_j) \text{ for all } j \in \{1, \ldots, p+q\}. \quad (9)$$

We are going to show that (8) and (9) uniquely determine the functions $f^I_j$ on $V$, i.e. the morphism $F$. Then the functions $g^I_j$ are unambiguously given by
Let us first describe the coefficients for the sequel of this proof. For fixed $I$, $\sum_{\mu=1}^p (\partial_{y_{\mu}} a^j_I)(\hat{F}(t,x)) \cdot f^\mu_K + R \left( a^j_I, f^\nu_I, \deg(I) < \deg(K) \right)$ (13)

if $\deg(K) > 0$.

Here for $I = (\alpha_1, \ldots, \alpha_n)$, $\deg(I) = \alpha_1 + \cdots + \alpha_n$, and -more importantly- $R = R_{j,I,K}$ is a polynomial function in $a^j_I$ and its derivatives in the $y$-variables up to order $q$ included, and in the functions $\{f^\nu_I \mid 1 \leq \nu \leq p+q, 0 \leq \deg(I) < \deg(K)\}$.

Equation (12) is obvious since $a^j_I$ is an even function, whereas equation (13) can be deduced from standard analysis on superdomains. More precisely, let $\hat{a}$ be a smooth function on $\mathbb{R}^p$ and $\hat{\psi} : \mathbb{R}^{n+1}\mathbb{R}^q \to \mathbb{R}^{p+q}$ a morphism (of course to be applied to $a = a^j_I, \hat{\psi} = \hat{F}$). Then we can develop $\hat{\psi}^*(a)$ as follows (compare the proof of Theorem 4.3.1 in [20]):

$$\hat{\psi}^*(a) = \sum_{\gamma} \frac{1}{\gamma!} (\partial_{\gamma_1} a)(\hat{\psi}^*(y_1), \ldots, \hat{\psi}^*(y_p)) \cdot \prod_{\mu=1}^p (\hat{\psi}^*(y_\mu) - \hat{\psi}^*(y_\mu))^{\gamma_\mu}$$

$$= a(\hat{\psi}(t,x)) + \sum_{\mu=1}^p (\partial_{y_{\mu}} a)(\hat{\psi}(t,x)) \cdot \left( \sum_{\nu \neq 0} f^\nu_M \cdot \xi^\nu \right) + \sum_{\mu=1}^P (\partial_{\gamma_1} a)(\hat{\psi}(t,x)) \cdot \prod_{\nu=1}^p (\hat{\psi}^*(y_\nu) - \hat{\psi}^*(y_\nu))^{\gamma_\nu}$$

For fixed $j$ this is an equation of Grassmann algebra-valued maps in the variables $t$ and $x$ that can be split in a system of scalar equations as follows. For $K = (\alpha_1, \ldots, \alpha_n) \in \{0,1\}^n$, we will denote the coefficient $h_K$ in front of $\xi^K$ of a superfunction $h = \sum_M h_M(t,x)\xi^M \in \mathcal{O}_{\mathbb{R}^{n+1}}$ compactly by $(h|\xi^K)$ in the sequel of this proof.

Let us first describe the coefficients for $\tilde{F}^*(a^j_I)$ in (11):

$$\tilde{F}^*(a^j_I)|\xi^K) = 0 \text{ if } |K| = 1$$

and, if $|K| = 0$,

$$(\tilde{F}^*(a^j_I)|\xi^K) = a^j_I \circ \tilde{F} \text{ if } K = (0, \ldots, 0),$$

and

$$\tilde{F}^*(a^j_I)|\xi^K) = \sum_{\mu=1}^P (\partial_{y_{\mu}} a^j_I)(\tilde{F}(t,x)) \cdot f^\mu_K + R \left( a^j_I, f^\nu_I, \deg(I) < \deg(K) \right) \text{ if } \deg(K) > 0.$$
\[ \frac{1}{2} \sum_{\mu',\mu''=1}^{p} (\partial_{\nu_{\mu}} \partial_{\nu_{\mu'}} a)(\tilde{\psi}(t,x)) \cdot \left( \sum_{M' \neq 0} f_{M'}^\mu \cdot \xi^{M'} \right) \cdot \left( \sum_{M'' \neq 0} f_{M''}^\mu \cdot \xi^{M''} \right) + \ldots, \]

where \( \sum_{M \neq 0} f_{M}^\mu \cdot \xi^{M} = \psi^s(y_{\mu}) - \tilde{\psi}^s(y_{\mu}) \) with \( f_{M}^\mu \) depending on \( t \) and \( x \). We observe that the last RHS is a finite sum since we work in the framework of finite-dimensional supermanifolds.

In order to get a contribution to \((\psi^s(a))^{\xi^K}\) we can either extract \( f_{K}^\mu \) from the “linear term” or from products coming from the higher order terms in the above development. Thus

\[
(\psi^s(a))^{\xi^K} = \sum_{\mu=1}^{p} (\partial_{\nu_{\mu}} a)(\tilde{\psi}(t,x)) \cdot f_{K}^\mu + R(a, (f_{J}^\mu)_{K, \deg(J) < \deg(K)}),
\]

where \( R \) is a polynomial as described after Equation (13).

Furthermore, for an element \( J = (\beta_{1}, \ldots, \beta_{q}) \) with \( |J| = 0 \) we have for \( \deg(K) > 0 \)

\[
\left( \prod_{s=1}^{q} \left( \sum_{|L|=1} f_{L}^{p+s} \xi^{L} \right)^{\beta_{s}} \right) \xi^{K} = R \left( (f_{J}^l)_{j, \deg(l) < \deg(K)} \right). \tag{14}
\]

And for an element \( J = (\beta_{1}, \ldots, \beta_{q}) \) with \( |J| = 1 \) we get for \( \deg(K) > 0 \)

\[
\left( \prod_{s=1}^{q} \left( \sum_{|L|=1} f_{L}^{p+s} \xi^{L} \right)^{\beta_{s}} \right) \xi^{K} = \begin{cases} f_{K}^{p+l} + R \left( (f_{J}^l)_{j, \deg(l) < \deg(K)} \right) & \text{if } \deg(J) = 1 \text{ and } l \in \{1, \ldots, q\} \\ \text{such that } \beta_{s} = \delta_{s,t} & \forall s, \end{cases} \tag{15}
\]

Obviously, the coefficient of \( \xi^{K} \) of the LHS of Equation (2) is given by

\[
\left( \sum_{|I|=|w_{j}|} \partial_{h} f_{I}^h \cdot \xi^{l} \right) \xi^{K} = \begin{cases} \partial_{h} f_{K}^h \xi^{l} & \text{if } |K| = |w_{j}| \\ 0 & \text{if } |K| = |w_{j}| + 1 \end{cases} \quad \text{for } 1 \leq j \leq p + q.
\]

Taking into account the above descriptions of the \( \xi^{K} \)-coefficients, we will show the existence (and uniqueness) of the solution functions \( \{f_{J}^l|1 \leq j \leq p + q, I \in \{0,1\}^n\} \) for \( (t,x) \in V \) by induction on \( \deg(I) \) and upon observing that all ordinary differential equations occuring are (inhomogeneous) linear equations for the unknown functions.
Let us start with \( \deg(I) = 0 \) that is \( I = (0, \ldots, 0) \). The “0-level” of the equations (11) and (9) is \( \partial_t f^I_j(0, \ldots, 0) = a^j(0, \ldots, 0) \circ \tilde{F} \) and \( f^I_j(0, \ldots, 0)(t_0, x) = y_j \circ \tilde{\phi}(x) \) for all \( j \) such that \( |w_j| = 0 \). We remark that \( f^I_j(0, \ldots, 0) \) is simply \( y_j \circ \tilde{F} \) and \( a^j(0, \ldots, 0) \) is \( \tilde{X}(y_j) \). Thus \( \tilde{F} \) is the flow of \( \tilde{X} \) with initial condition \( \tilde{\phi} \) at \( t = t_0 \), i.e., \( \tilde{F} = H \) on \( V \). Thus the claim is true for \( I = (0, \ldots, 0) \).

Suppose \( k > 0 \) and that the functions \( f^j_I \) are uniquely defined on \( V \) for all \( j \) and all \( I \) such that \( \deg(I) < k \). Let \( K \) be such that \( \deg(K) = k \). Let us distinguish the two possible parities of \( k \) in order to determine \( f^j_K \) for all \( j \).

Recall that \( f^j_K = 0 \) if the parities of \( K \) and \( j \) are different.

If \( k \) is even, i.e., \( |K| = 0 \), we only have to consider \( j \) such that \( |w_j| = 0 \). Putting (12) and (11) together, we find in this case

\[
\partial_t f^I_K = \left( \sum_{|J|=0} \tilde{F}^*(a^j_J) \prod_{s=1}^{|J|} \left( \sum_{|L| = 1} f^{I+s}_L \xi^L \right)^{\beta_s} \right) \xi^K \\
= \left( \sum_{\deg(J) = 0} \tilde{F}^*(a^j_J) \prod_{s=1}^{|J|} \left( \sum_{|L| = 1} f^{I+s}_L \xi^L \right)^{\beta_s} \right) + \sum_{\deg(J) > 0} \tilde{F}^*(a^j_J) \prod_{s=1}^{|J|} \left( \sum_{|L| = 1} f^{I+s}_L \xi^L \right)^{\beta_s} \xi^K \\
= \left( \tilde{F}^*(a^j(0, \ldots, 0)) + \sum_{\deg(J) > 0} \tilde{F}^*(a^j_J) \prod_{s=1}^{|J|} \left( \sum_{|L| = 1} f^{I+s}_L \xi^L \right)^{\beta_s} \right) + \sum_{\mu=1}^p \left( \partial_{y_\mu} a^j(0, \ldots, 0) \circ \tilde{F} \right) f^j_K + R \left( (a^j_J)_J, (f^j_L)_L, \deg(J) < \deg(K) \right).
\]

Moreover, the initial condition gives \( f^j_K(t_0, x) = (\phi^*(y_j))(\xi^K) \), for all \( j \) in \( \{1, \ldots, p\} \). Since the \( a^j_J \) are the (given) coefficients of the vector field \( X \) and the functions \( f^j_I \) with \( \deg(I) < k \) are known by the induction hypothesis, we have a unique local solution function \( f^j_K \). Since the ordinary differential equation for \( f^j_K \) is linear its solution is already defined for all \( (t, x) \in V \). Thus in the case that \( k \) is even \( f^j_K \) is unambiguously defined on \( V \) for all \( j \in \{1, \ldots, p + q\} \) and for all \( K \) with \( \deg(K) = k \).
Now, if \( k \) is odd, i.e., \(|K| = 1\), we only have to consider \( j \) such that \(|w_j| = 1\). Using (13) and (15), we find in this case:

\[
\partial_t f_K^j = \left( \sum_{|J|=1} F^*(a_j^I) \prod_{s=1}^q \left( \sum_{|L|=1} f_L^{p+s} \xi \right)^{\beta_s} \left| \xi^K \right) \right)
\]

\[
= \left( \sum_{\text{deg}(J)=1} F^*(a_j^I) \prod_{s=1}^q \left( \sum_{|L|=1} f_L^{p+s} \xi \right)^{\beta_s} \left| \xi^K \right) \right)
\]

\[
+ \sum_{\text{deg}(J)>1} F^*(a_j^I) \prod_{s=1}^q \left( \sum_{|L|=1} f_L^{p+s} \xi \right)^{\beta_s} \left| \xi^K \right)
\]

\[
= \sum_{s=1}^q F^*(a_j^I) \left( \sum_{|L|=1} f_L^{p+s} \xi \right)
\]

\[
+ \sum_{\text{deg}(J)>1} F^*(a_j^I) \prod_{s=1}^q \left( \sum_{|L|=1} f_L^{p+s} \xi \right)^{\beta_s} \left| \xi^K \right)
\]

\[
= \sum_{s=1}^q \left( a_j^I \right) \circ F \sum_{|L|=1} f_L^{p+s} + R \left( (a_j^I)_I, (f_I^*)_{\nu, \text{deg}(I)<\text{deg}(K)} \right).
\]

Moreover, the initial condition gives

\[
f_K^j(t_0, x) = (\phi^*(w_j))^{\xi^K} \text{ for all } j \text{ in } \{p+1, \ldots, p+q\}.
\]

It follows as in the case of \(|K| = 0\), that \(f_K^j\) exists uniquely for all \((t, x) \in V\), for all \(j \in \{1, \ldots, p+q\}\) and for all \(K\) with \(\text{deg}(K) = k\).

We conclude that the functions \(\{f_I^j\}_{1 \leq j \leq p+q, I \in \{0,1\}^n}\) are uniquely defined on the whole of \(V\). Since the \(\{g_I^j\}_{1 \leq j \leq p+q, I \in \{0,1\}^n}\) are determined by Equation (18) from the \(\{f_I^j\}_{1 \leq j \leq p+q}\) via comparison of coefficients, the morphism \(F : \mathcal{V} \to \mathcal{V}\) is uniquely determined. \(\Box\)

We now consider the global problem of integrating a vector field on a supermanifold. In order to prove that there exists a unique maximal flow of a vector field, the following lemma will be crucial.
**Lemma 2.2.** Let $\mathcal{M} = (M, \mathcal{O}_M)$ and $S = (S, \mathcal{O}_S)$ be supermanifolds, $X$ a vector field in $T_M(M)$ and $\phi$ in $\text{Mor}(S, \mathcal{M})$. Then

(i) there exists an open sub supermanifold $V = (V, \mathcal{O}_{\mathbb{R}^{1|1} \times S}|_V)$ of $\mathbb{R}^{1|1} \times S$ with $V$ open in $\mathbb{R} \times S$ such that $\{0\} \times S \subset V$ and for all $x$ in $S$, $(\mathbb{R} \times \{x\}) \cap V$ is an interval, and a morphism $F : V \to \mathcal{M}$ satisfying:

\[
\text{inj}_{\mathbb{R}^{1|1}}^* \circ (\partial_t + \partial_x) \circ F^* = \text{inj}_{\mathbb{R}^{1|1}}^* F^* \circ X \quad \text{and} \quad \tag{16}
\]

\[
F \circ \text{inj}_{\{0\} \times S} = \phi . \quad \tag{17}
\]

(ii) Let furthermore $F_1 : V_1 \to \mathcal{M}$ and $F_2 : V_2 \to \mathcal{M}$ be morphisms satisfying (17) and (14) where $V_i = (V_i, \mathcal{O}_{\mathbb{R}^{1|1} \times S}|_{V_i})$ with $V_i$ open in $\mathbb{R} \times S$ such that $\{0\} \times S \subset V_i$, and for all $x$ in $S$, $(\mathbb{R} \times \{x\}) \cap V_i$ is an interval, for $i = 1, 2$. Then $F_i|_{V_{12}} = F_2|_{V_{12}}$ on $V_{12} = (V_{12}, \mathcal{O}_{\mathbb{R}^{1|1} \times S}|_{V_{12}})$, where $V_{12} = V_1 \cap V_2$.

**Proof:** (i) Let $\tilde{\phi} : S \to M$ denote the induced map of the underlying classical manifolds. Given now $s$ in $S$ and coordinate domains $U_s$ of $\tilde{\phi}(s)$, isomorphic to superdomains $U_s \subset \mathbb{R}^{m|n}$ resp. $W_s \subset \mathbb{R}^{p|q}$, by Lemma 2.1 we get solutions of (15) and (17) near $s$ (upon reducing the size of $U_s$ if necessary): $\mathbb{R}^{1|1} \times S \supset \mathbb{R}^{1|1} \times U_s \supset V_s \xrightarrow{F^s} W_s \subset \mathcal{M}$. If $V_{s_1} \cap V_{s_2} \neq \emptyset$ (compare Figure 1) we know, again by Lemma 2.1 that $F^{s_1}$ and $F^{s_2}$ coincide on this intersection. Thus, by taking the union $\mathcal{V}$ of $V_s$ for all $s$ in $S$, we get a morphism $F : \mathbb{R}^{1|1} \times S \supset \mathcal{V} \to \mathcal{M}$ such that $F|_{V_s} = F^s$ for all $s$, and fulfilling (16) and (17).

![Figure 1](image)

(ii) We define $A$ as the set of points $(t, x) \in V_{12}$ such that there exists $\epsilon = \epsilon_{(t,x)} > 0$ and $U = U_{(t,x)}$ an open sub supermanifold of $S$, such that its body $U$ contains $x$ and for $\mathcal{V} = V_{(t,x)} = (V_{(t,x)}, \mathcal{O}_{\mathbb{R}^{1|1} \times S}) = (\{0\} \times U, \mathcal{O}_{\mathbb{R}^{1|1} \times S})$ we have $F_1|_{\mathcal{V}} = F_2|_{\mathcal{V}}$. Of course, if $t < 0$ the interval will be of the type $[t - \epsilon, \epsilon]$ (See Figure 2). The claim of the Lemma is now equivalent to $A = V_{12}$. The set $A$ is obviously open.
By an easy application of Lemma 2.1, $A$ contains $\{0\} \times S$. The assumptions imply that for all $x \in S$, the set $I_x \subset \mathbb{R}$, defined by $(\mathbb{R} \times \{x\}) \cap \mathcal{V}_{12} = I_x \times \{x\}$, is an open interval containing 0. The definition of $A$ implies that the set $J_x \subset CA$ defined by $(\mathbb{R} \times \{x\}) \cap \mathcal{V}_{12} = J_x \times \{x\}$, is an open interval containing 0 as well.

Assuming now that $A \neq \mathcal{V}_{12}$, then there exists a point $(t, x_0) \in \mathcal{V}_{12} \setminus A$ such that $J_{x_0} \neq I_{x_0}$. Without loss of generality we can assume that $t > 0$ and that for $0 \leq t' < t$, $(t', x_0) \in A$. Let $U_0$ be an open coordinate neighborhood of $x_0$ in $S$ and $\delta > 0$ such that, with $V_0 := ]t - \delta, t + \delta[ \times U_0 \subset \mathcal{V}_{12}$, $H(V_0) \subset W$, where $W = (W, \mathcal{O}_M |_W)$ is a coordinate patch of $M$ and $H$ is the maximal flow of $\tilde{X}$ as in Lemma 2.1. Choose $t_0 \in ]t - \delta, t[$. Then $(t_0, x_0) \in A$ and thus there exists $\epsilon > 0$ and $U$ an open sub supermanifold of $U_0 = (U_0, \mathcal{O}_S |_{U_0})$ containing $x_0$ such that

$$F_1 |_{V} = F_2 |_{V}, \quad \text{where } V = ]t - \epsilon, t_0 + \epsilon[ \times \mathbb{R}^{0|1} \times U \subset \mathcal{V}_{12}. \quad (18)$$

On $V' = ]t - \delta, t + \delta[ \times \mathbb{R}^{0|1} \times U \subset \mathcal{V}_{12}$, $F_1$ and $F_2$ are defined and for $i = 1, 2$ the maps $F_i \circ \text{inj} |_{[t_0] \times U}$ coincide by (13) (Compare Figure 3 for the relative positions of the underlying topological spaces of these open sub supermanifolds of $\mathbb{R}^{0|1} \times S$).
By Lemma 2.1 we have $F_1|_{V'} = F_2|_{V'}$. Thus $F_1 = F_2$ on $V \cup V'$, and we conclude that $(t, x_0) \in A$. This contradiction shows that $V_{12} = A$.

Remarks. (1) Obviously, Lemma 2.2 holds true for an arbitrary $t_0 \in \mathbb{R}$ replacing $t_0 = 0$.

(2) Let us call a “flow domain for $X$ with initial condition $\phi \in \text{Mor}(\mathcal{S}, \mathcal{M})$ (with respect to $t_0 \in \mathbb{R}$)“ a domain $V \subset \mathbb{R}^{1|1} \times \mathcal{S}$ such that $\{t_0\} \times \mathcal{S} \subset V$ and for all $s$ in $\mathcal{S}$, $(\mathbb{R} \times \{s\}) \cap V$ is connected, i.e. an interval (times $\{s\}$) and such that a solution $F$ (a “flow”) of (16) and (17) exists on $V$. By the preceding lemma there exists such “flow domains”.

Theorem 2.3. Let $\mathcal{M}$ and $\mathcal{S}$ be supermanifolds, $X$ be a vector field in $\mathcal{T}_\mathcal{M}(\mathcal{M})$, $\phi \in \text{Mor}(\mathcal{S}, \mathcal{M})$ and $t_0$ in $\mathbb{R}$. Then there exists a unique map $F : V \to \mathcal{M}$ such that

$$(\text{inj}_{\mathbb{R}})^* \circ (\partial_t + \partial_x) \circ F^* = (\text{inj}_{\mathbb{R}})^* \circ F^* \circ X \quad \text{and} \quad F \circ \text{inj}_{\{t_0\} \times \mathcal{S}} = \phi,$$

where $V = (V, \mathcal{O}_{\mathbb{R}^{1|1} \times \mathcal{U}}|_V)$ is the maximal flow domain for $X$ with the given initial condition.

Moreover, $\tilde{F} : V \to \mathcal{M}$ is the maximal flow of $\tilde{X} \in \mathcal{X}(\mathcal{M})$ subject to the initial condition $\tilde{\phi}$ at $t = t_0$.

Proof. The proof of the theorem follows immediately from the Lemmata 2.1 and 2.2 upon taking the union of all flow domains and flows for $X$ as defined in the preceding remark.

3 Supervector fields and local $\mathbb{R}^{1|1}$-actions

Given a vector field on a classical, ungraded, manifold, the flow map $\tilde{F}$ (for $S = \mathcal{M}, \tilde{\phi} = \text{id}_{\mathcal{M}}$) is always a local action of $\mathbb{R}$ with its usual (and unique up to isomorphism) Lie group structure, the standard addition. The flow maps for vector fields described in the preceding section (taking here $S = \mathcal{M}, \phi = \text{id}_{\mathcal{M}}$), do not always have the analogous property of being local actions of $\mathbb{R}^{1|1}$ with an appropriate Lie supergroup structure. Two characterizations of those vector fields $X = X_0 + X_1$ that generate a local $\mathbb{R}^{1|1}$-action were found by J. Monterde and O. A. Sánchez-Valenzuela. We will give in this section a short proof of a slightly more general result, whose condition (iii) seems to be more easily verified in practice than those given in (13) (compare Thm. 3.6 and its proof there).

Let us begin by giving a useful two-parameter family of Lie supergroup structures on the supermanifold $\mathbb{R}^{1|1}$ and their right invariant vector fields.

Lemma 3.1. Let $a$ and $b$ be real numbers such that $a \cdot b = 0$ and $\mu_{a,b} = \mu : \mathbb{R}^{1|1} \to \mathbb{R}^{1|1}$
\( R^{1|1} \times R^{1|1} \to R^{1|1} \) be defined by

\[
\widetilde{\mu}(t_1, t_2) = t_1 + t_2, \\
\mu^*(t) = t_1 + t_2 + a \tau_1 \tau_2, \\
\mu^*(\tau) = \tau_1 + e^{bt_1} \tau_2.
\]

Then

(i) there exists a unique Lie supergroup structure on \( R^{1|1} \) such that the multiplication morphism is given by \( \mu_{a,b} \),

(ii) the right invariant vector fields on \( (R^{1|1}, \mu_{a,b}) \) are given by the graded vector space \( RD_0 \oplus RD_1 \), where

\[
D_0 := \partial_t + b \cdot \tau \partial_\tau \quad \text{and} \quad D_1 := \partial_\tau + a \cdot \tau \partial_t.
\]

and they obey \([D_0, D_0] = 0, [D_0, D_1] = -bD_1 \) and \([D_1, D_1] = 2aD_0\).

PROOF. Both assertions follow by straightforward verifications. \( \square \)

REMARKS. (1) It can easily be checked that the above family yields only three non-isomorphic Lie supergroup structures on \( R^{1|1} \), since \( (R^{1|1}, \mu_{a,0}) \) with \( a \neq 0 \) is isomorphic to \( (R^{1|1}, \mu_{1,0}) \) and \( (R^{1|1}, \mu_{0,b}) \) with \( b \neq 0 \) is isomorphic to \( (R^{1|1}, \mu_{0,1}) \) and the three multiplications \( \mu_{0,0}, \mu_{1,0} \) and \( \mu_{0,1} \) correspond to non-isomorphic Lie supergroup structures on \( R^{1|1} \). Nevertheless it is very convenient to work here with the more flexible two-parameter family of multiplications.

(2) In fact, all Lie supergroup structures on \( R^{1|1} \) are equivalent to \( \mu_{0,0}, \mu_{1,0} \) or \( \mu_{0,1} \). See, e.g., [4] for a direct approach to the classification of all Lie supergroup structures on \( R^{1|1} \).

DEFINITION 3.2. Let \( G = (G, O_G) \) resp. \( M = (M, O_M) \) be a Lie supergroup with multiplication morphism \( \mu \) and unit element \( e \) resp. a supermanifold. A “local action of \( G \) on \( M \)” is given by the following data:

a collection \( \Pi \) of pairs of open subsets \( \pi = (U_\pi, W_\pi) \) of \( M \), where \( U_\pi \) is relatively compact in \( W_\pi \), such that \( \{U_\pi, \pi \in \Pi\} \) is an open covering of \( M \), and for all \( \pi \) in \( \Pi \) an open sub supermanifold \( \mathcal{G}_\pi \subset G \), containing the neutral element \( e \) and a morphism

\[
\Phi_\pi : \mathcal{G}_\pi \times U_\pi \to W_\pi
\]

fulfilling

(1) \( \Phi_\pi \circ (e \times id_{U_\pi}) = id_{U_\pi}, \) where \( e : \{pt\} \to G \) is viewed as a morphism,

(2) \( \Phi_\pi \circ (\mu \times id_M) = \Phi_\pi \circ (id_G \times \Phi_\pi), \) where both sides are defined,

(3) if \( U_\pi \cap U_{\pi'} \neq \emptyset, \Phi_\pi = \Phi_{\pi'} \) on \( (\mathcal{G}_\pi \cap \mathcal{G}_{\pi'}) \times (U_\pi \cap U_{\pi'}). \)

DOCUMENTA MATHEMATICA 18 (2013) 519–545
Proposition 3.3. Let $G = (G, O_G)$ resp. $M = (M, O_M)$ be a Lie supergroup resp. a supermanifold. Then

(i) a local $G$-action on $M$, specified by a set $\Pi$ and morphisms $\{(U_\pi, \omega_\pi, G_\pi, \Phi_\pi) | \pi \in \Pi\}$, gives rise to an open sub supermanifold $V \subset G \times M$ containing $\{e\} \times M$ and a morphism $\Phi_V : V \to M$ such that
\[ \Phi_V \circ (\mu \times id_M) = \Phi_V \circ (id_G \times \Phi_V), \]
where both sides are defined and such that $\Phi_\pi = \Phi_V$ on $(G_\pi \times U_\pi) \cap V, \forall \pi \in \Pi$.

(ii) an open sub supermanifold $V \subset G \times M$ containing $\{e\} \times M$ and a morphism $\Phi_V : V \to M$ such that $(\ast)$ is fulfilled, where it makes sense, yields a local $G$-action on $M$ such that $(\ast\ast)$ holds.

Proof. As in the classical case of ungraded manifolds and Lie groups. □

Theorem 3.4. Let $M$ be a supermanifold, $X$ a vector field on $M$ and $V \subset \mathcal{R}^{1|1} \times M$ the domain of the maximal flow $F : V \to M$ satisfying
\[ (\text{inj}_{\mathcal{R}^{1|1}})^* \circ (\partial_t + \partial_\tau) \circ F^* = (\text{inj}_{\mathcal{R}^{1|1}})^* \circ F^* \circ X \text{ and} \]
\[ F \circ \text{inj}_{\mathcal{R}^{1|1}} \mid_{\{0\} \times M} = id_M. \]

Let $a$ and $b$ be real numbers such that $a \cdot b = 0$. Then the following assertions are equivalent:

(i) the map $F$ fulfills
\[ (\partial_t + \partial_\tau + \tau (a\partial_t + b\partial_\tau)) \circ F^* = F^* \circ X, \]

(ii) the map $F$ is a local $(\mathcal{R}^{1|1}, \mu_{a,b})$-action on $M$,

(iii) $\mathcal{R}X_0 \oplus \mathcal{R}X_1$ is a sub Lie superalgebra of $\mathcal{T}_M(M)$ with commutators $[X_0, X_1] = -bX_1$ and $[X_1, X_1] = 2aX_0$.

Proof. Recall that $F$ fulfills
\[ (\text{inj}_{\mathcal{R}^{1|1}})^* \circ \partial_t \circ F^* = (\text{inj}_{\mathcal{R}^{1|1}})^* \circ F^* \circ X_0 \text{ and} \]
\[ (\text{inj}_{\mathcal{R}^{1|1}})^* \circ \partial_\tau \circ F^* = (\text{inj}_{\mathcal{R}^{1|1}})^* \circ F^* \circ X_1. \]

Denoting the projection from $\mathcal{R}^{1|1}$ to $\mathcal{R}$ by $p$, we have
\[ \text{id}_{\mathcal{R}^{1|1}}^* = p^* \circ (\text{inj}_{\mathcal{R}^{1|1}})^* + \tau \cdot p^* \circ (\text{inj}_{\mathcal{R}^{1|1}})^* \circ \partial_\tau \]
which we will write more succinctly as
\[ \text{id}_{\mathcal{R}^{1|1}}^* = \tau \cdot (\text{inj}_{\mathcal{R}^{1|1}})^* \circ \partial_\tau. \]
Using relation (19) and the equations fulfilled by $F^*$ we get

\[ F^* \circ X = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \circ X + \tau \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_t \circ F^* \circ X \]

\[ = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ (\partial_t + \partial_r) \circ F^* + \tau \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \circ X_1 \circ X \]

\[ = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ (\partial_t + \partial_r) \circ F^* + \tau \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \]

\[ + \tau \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \circ \left( [X_1, X_0] + X_0 \circ X_1 + \frac{1}{2} [X_1, X_1] \right). \]

Since

\[ (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \circ X_0 \circ X_1 = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_t \circ F^* \circ X_1 \]

\[ = \partial_t \circ (\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* \circ X_1 \]

\[ = \partial_t \circ (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_r \circ F^* \]

\[ = \partial_t \circ \partial_r \circ F^* \]

we arrive at

\[ F^* \circ X = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ (\partial_t + \partial_r) \circ F^* + \]

\[ \tau \cdot F^* \circ \left( [X_1, X_0] + \frac{1}{2} [X_1, X_1] \right) + \tau \cdot \partial_r \circ \partial_t \circ F^*. \quad (20) \]

On the other hand, if $a$ and $b$ are real numbers, we have, again using (19)

\[ (\partial_t + \partial_r + \tau (a \partial_t + b \partial_r)) \circ F^* \]

\[ = \left( (\text{inj}_R^{\mathbb{R}^{11}})^* + \tau \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_r \right) \circ (\partial_t + \partial_r) \circ F^* \]

\[ + \tau \cdot \left( a \circ (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_t + b \cdot (\text{inj}_R^{\mathbb{R}^{11}})^* \circ \partial_r \right) \circ F^* \]

\[ = (\text{inj}_R^{\mathbb{R}^{11}})^* \circ (\partial_t + \partial_r) \circ F^* + \tau \cdot \partial_r \circ \partial_t \circ F^* \]

\[ + \tau \cdot F^* \circ (a X_0 + b X_1). \]

Thus we have

\[ (\partial_t + \partial_r + \tau (a \partial_t + b \partial_r)) \circ F^* = F^* \circ X \]

\[ = \tau \cdot F^* \circ \left( a X_0 - \frac{1}{2} [X_1, X_1] + b X_1 - [X_1, X_0] \right). \quad (21) \]

Since $F$ satisfies the initial condition $(\text{inj}_R^{\mathbb{R}^{11}})^* \circ F^* = \text{id}_M$, $\tau \cdot F^*$ is injective and thus Equation (21) easily implies the equivalence of (i) and (iii).

We remark that, in this case, we automatically have $a \cdot b = 0$ since the Jacobi identity implies that $[X_1, [X_1, X_1]] = [[X_1, X_1], X_1] + (-1)^{[1]} \cdot [X_1, [X_1, X_1]]$, i.e., $2a \cdot b \cdot X_1 = [X_1, [X_1, X_1]] = 0$. 

\[ \text{Documenta Mathematica 18 (2013) 519–545} \]
Assume now that \( a \) and \( b \) are real numbers such that \((i)\) satisfied, and let \( \mu = \mu_{a,b} \) be as in Lemma 5.1. We have to show that \( F \) is a local action of \((\mathbb{R}^{1|1}, \mu)\).

Let us define
\[
G := F \circ (\text{id}_{\mathbb{R}^{1|1}} \times F) : \mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M}) \to \mathcal{M}
\]
and
\[
H := F \circ (\mu \times \text{id}_{\mathcal{M}}) : (\mathbb{R}^{1|1} \times \mathbb{R}^{1|1}) \times \mathcal{M} \cong (\mathbb{R}^{1|1} \times \mathcal{M}) \to \mathcal{M}.
\]

In order to prove that \( F \) is a \( \mathbb{R}^{1|1} \)-action on, we have to show that \( G = H \).

We observe that \( G \) is the integral curve of \( X \) subject to the initial condition \( F \in \text{Mor}(\mathbb{R}^{1|1} \times \mathcal{M}, \mathcal{M}) \).

Let us prove that the morphism \( H \) satisfies the following conditions:
\[
\left( \text{inj}_{\mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M})} \right)^{*} \circ (\partial_{t_1} + \partial_{t_1}) \circ H^{*} = \left( \text{inj}_{\mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M})} \right)^{*} \circ H^{*} \circ X \quad (22)
\]
\[
H \circ \text{inj}_{\{0\} \times (\mathbb{R}^{1|1} \times \mathcal{M})}^{\mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M})} = F. \quad (23)
\]

Then by the unicity of integral curves we have \( H = G \).

Equation (23) holds true since \( \mu \circ \text{inj}_{\{0\} \times \mathbb{R}^{1|1}} = \text{id}_{\mathbb{R}^{1|1}} \).

Defining \( D := D_0 + D_1 = \partial_{t_1} + \partial_{t_1} + \tau_1(a \partial_{t_1} + b \partial_{t_1}) \) and writing \( \text{inj}_{[t_1]} \) for \( \text{inj}_{\mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M})} \) and using right invariance of \( D \), we arrive at equation (22) as follows
\[
\left( \text{inj}_{\mathbb{R}^{1|1} \times (\mathbb{R}^{1|1} \times \mathcal{M})} \right)^{*} \circ (\partial_{t_1} + \partial_{t_1}) \circ H^{*} = (\text{inj}_{[t_1]})^{*} \circ D \circ H^{*} = (\text{inj}_{[t_1]})^{*} \circ (D \otimes \text{id}_{\mathbb{R}^{1|1}}) \circ \mu^{*} \times \text{id}_{\mathcal{M}} \circ F^{*} = (\text{inj}_{[t_1]})^{*} \circ (\mu^{*} \circ D) \times \text{id}_{\mathcal{M}} \circ F^{*} = (\text{inj}_{[t_1]})^{*} \circ (\mu^{*} \times \text{id}_{\mathcal{M}}) \circ F^{*} \circ X = (\text{inj}_{[t_1]})^{*} \circ H^{*} \circ X.
\]

Thus we obtain that \((i)\) implies \((ii)\).

Assume now that \((ii)\) is satisfied, i.e., there exists a Lie supergroup structure on \( \mathbb{R}^{1|1} \) with multiplication \( \mu \) such that
\[
F \circ (\text{id}_{\mathbb{R}^{1|1}} \times F) = F \circ (\mu \times \text{id}_{\mathcal{M}}). \quad (24)
\]

Since \( F \) is a flow for \( X \), with initial condition \( \phi = \text{id}_{\mathcal{M}} \), the LHS of the preceding equality is a flow for \( X \) with initial condition \( \phi = F \), (24) implies
\[
\left( \text{inj}_{[t_1]} \right)^{*} \circ (\partial_{t_1} + \partial_{t_1}) \circ (\mu^{*} \times \text{id}_{\mathcal{M}}) \circ F^{*} = \left( \text{inj}_{[t_1]} \right)^{*} \circ (\mu^{*} \times \text{id}_{\mathcal{M}}) \circ F^{*} \circ X. \quad (25)
\]

Proof completed.
By Equation (20), the RHS gives for $t_1 = 0$:

$$\begin{align*}
\left(\text{inj}_{|t_1=0}\right)^* \circ (\mu^* \times \text{id}_M^*) \circ F^* \circ X &= F^* \circ X \\
&= \left(\text{inj}_{\mathbb{R}_{\mu}}\right)^* \circ (\partial_t + \partial_{\tau}) \circ F^* \\
&+ \tau \cdot \left[ F^* \circ \left( [X_1, X_0] + \frac{1}{2}[X_1, X_1] \right) + \partial_{\tau} \circ \partial_t \circ F^* \right].
\end{align*}$$

Moreover, we have by direct comparison

$$(\partial_t + \partial_{\tau}) \circ \mu^* = (\partial_t + \partial_{\tau})(\mu^*(t)) \cdot (\mu^* \circ \partial_t) + (\partial_t + \partial_{\tau})(\mu^*(\tau)) \cdot (\mu^* \circ \partial_{\tau}).$$

Thus, if $\mu : \mathbb{R}^{1|1} \times \mathbb{R}^{1|1} \to \mathbb{R}^{1|1}$ is given by

$$\begin{align*}
\mu^*(t) &= \tilde{\mu}(t_1, t_2) + \alpha(t_1, t_2)\tau_1 \tau_2 \\
\mu^*(\tau) &= \beta(t_1, t_2)\tau_1 + \gamma(t_1, t_2)\tau_2,
\end{align*}$$

and upon using $\left(\text{inj}_{\{0\} \times \mathbb{R}^{1|1}}\right)^* \circ \mu^* = \text{id}_{\mathbb{R}^{1|1}}^*$, we have

$$\begin{align*}
\left(\text{inj}_{\{0\} \times \mathbb{R}^{1|1}}\right)^* (\partial_t + \partial_{\tau}) \circ \mu^* &= ((\partial_t, \tilde{\mu})(0, t) + \alpha(0, t)\tau) \cdot \partial_t \\
&+ (\beta(0, t) + (\partial_t, \gamma)(0, t)\tau) \cdot \partial_{\tau}.
\end{align*}$$

Using again (19), we have

$$\begin{align*}
\partial_t \circ F^* &= \left(\text{inj}_{\mathbb{R}^{1|1}}\right)^* \circ F^* \circ X_0 + \tau \cdot \partial_{\tau} \circ \partial_t \circ F^* \quad \text{and} \\
\partial_{\tau} \circ F^* &= \left(\text{inj}_{\mathbb{R}^{1|1}}\right)^* \circ F^* \circ X_1.
\end{align*}$$

Then the LHS of (25) at $t_1 = 0$ is

$$\begin{align*}
\left(\text{inj}_{|t_1=0}\right)^* \circ (\partial_t + \partial_{\tau}) \circ (\mu^* \times \text{id}_M^*) \circ F^* \\
= (\partial_t, \tilde{\mu})(0, t) \cdot \left(\text{inj}_{\mathbb{R}^{1|1}}\right)^* \circ F^* \circ X_0 \\
+ \beta(0, t) \cdot \left(\text{inj}_{\mathbb{R}^{1|1}}\right)^* \circ F^* \circ X_1 \\
+ \tau \cdot \left( (\partial_t, \tilde{\mu})(0, t) \cdot \partial_{\tau} \circ \partial_t \circ F^* \\
+ \alpha(0, t) \cdot F^* \circ X_0 \\
+ (\partial_t, \gamma)(0, t) \cdot F^* \circ X_1 \right).
\end{align*}$$

Using the obtained identities for its LHS and RHS, the “$\tau$-part” of Equation (25) at $t_1 = 0$ gives us:

$$\begin{align*}
\tau \cdot \left[ F^* \circ \left( [X_1, X_0] + \frac{1}{2}[X_1, X_1] \right) + \partial_{\tau} \circ \partial_t \circ F^* \right] \\
= \tau \cdot [ (\partial_t, \tilde{\mu})(0, t) \cdot \partial_{\tau} \circ \partial_t \circ F^* + \alpha(0, t) \cdot F^* \circ X_0 + (\partial_t, \gamma)(0, t) \cdot F^* \circ X_1 ].
\end{align*}$$
Since \( \tilde{\mu}(t_1,0) = t_1 \), we have \( (\partial_{t_1}\tilde{\mu})(0,0) = 1 \) and therefore the preceding equation evaluated at \( t = 0 \) yields
\[
[X_1,X_0] + \frac{1}{2}[X_1,X_1] = (\partial_{t_1}\gamma)(0,0) \cdot X_1 + \alpha(0,0) \cdot X_0
\]
finishing the proof that \((ii)\) implies \((iii)\).

\( \square \)

### 4 Examples and applications

(4.1) If \( X = X_0 \) is an even vector field, the fact that it integrates to a (local) action of \( \mathbb{R} = \mathbb{R}^{1|0} \) is almost folkloristic. The relatively recent proof of \( \mathbb{R} \) - in the case of compact supermanifolds - is close to our approach. A non-trivial (local) action of \( \mathbb{R}^{1|1} \) can obviously be extended to a (local) action of \( (\mathbb{R}^{1|1},\mu_{a,b}) \) if and only if \( a = 0 \). Of course, the ensuing action of \( \mathbb{R}^{0|1} \) will not even be almost-effective, since the positive-dimensional sub Lie supergroup \( \mathbb{R}^{0|1} \) acts trivially.

(4.2) Our preferred example of an even vector field gives rise to the exponential map on Lie supergroups.

Let us first recall that an even vector field \( X \) on a supermanifold \( M \) corresponds to a section \( \sigma_X \) of the tangent bundle \( TM \to M \) (see, e.g., Sections 7 and 8 of \( \mathbb{R} \) for a construction of \( TM \) and a proof of this statement, and compare also the remark after Thm. 2.19 in \( \mathbb{R} \)). Given an auxiliary supermanifold \( S \) and a morphism \( \psi : S \to M \), one calls for \( i \in \{0,1\} \)
\[
\text{Der}_\psi(\mathcal{O}_M(M),\mathcal{O}_S(S)) := \{ D : \mathcal{O}_M(M) \to \mathcal{O}_S(S) | D \text{ is } \mathbb{R}-\text{linear and } \forall f,g \in \mathcal{O}_M(M) \text{ homogeneous,} \}
\]
\[
D(f \cdot g) = D(f) \cdot \psi^*(g) + (\pm 1)^i [\psi^*(f) \cdot D(g)],
\]
the “space of derivations of parity \( i \) along \( \psi \)”. In category-theoretical terms the tangent bundle \( TM \) represents then the functor from supermanifolds to sets given by \( S \mapsto \{ (\psi,D) | \psi \in \text{Mor}(S,M) \text{ and } D \in \text{Der}_\psi(\mathcal{O}_M(M),\mathcal{O}_S(S)) \} \) (compare, e.g., Section 3 of \( \mathbb{R} \)).

Let now \( G = (G,\mathcal{O}_G) \) be a Lie supergroup with multiplication \( \mu = \mu_G \) and neutral element \( e \). We define \( X \) in \( \text{Der}(\mathcal{O}_{T_eG}(G \times T_eG)) \) to be the even vector field on \( G \times T_eG \) corresponding to the following section \( \sigma_X \) of \( T\tilde{G} \times T\tilde{T}_e\tilde{G} \cong T(\tilde{G} \times T_e\tilde{G}) \to \tilde{G} \times T_e\tilde{G} \). We denote the zero-section of \( T\tilde{G} \to \tilde{G} \) by \( \sigma_0 \) and the canonical inclusion \( T_e\tilde{G} \to \tilde{G} \) by \( i_e \). Then \( \sigma_X := (T\mu \circ (\sigma_0 \times i_e),0) \), where \( T\mu : T\tilde{G} \times T\tilde{G} \cong T(\tilde{G} \times \tilde{G}) \to T\tilde{G} \) is the tangential morphism associated to the multiplication morphism. (For simplicity, we write 0 for the zero-section of \( T(T_e\tilde{G}) \to T_e\tilde{G} \) here and in the sequel.)
Let us recall that for $\mathcal{S}$ an arbitrary supermanifold, and $\phi : \mathcal{M} \to \mathcal{N}$ a morphism between supermanifolds, we have an induced map $\phi(S) : \mathcal{M}(S) = \text{Mor}(\mathcal{S}, \mathcal{M}) \to \text{Mor}(\mathcal{S}, \mathcal{N}) = \mathcal{N}(\mathcal{S})$, $\phi(S)(\psi) := \phi \circ \psi$. Given a finite-dimensional Lie superalgebra $\mathfrak{g}$ or a Lie supergroup $\mathcal{G}$, one easily checks that for all $k \geq 0$, $\mathfrak{g}(\mathbb{R}^{0|k})$ resp. $\mathcal{G}(\mathbb{R}^{0|k})$ is a finite-dimensional classical (i.e. even) Lie algebra resp. Lie group. Furthermore, $T_e(\mathcal{G}(\mathbb{R}^{0|k}))$ is canonically isomorphic to $(T_e\mathcal{G})(\mathbb{R}^{0|k})$, where the first $e$ is the obvious constant morphism from $\mathbb{R}^{0|k}$ to $\mathcal{G}$ and the second $e$ denotes the neutral element of $\mathcal{G}$. (Compare, e.g., [16] for more information on the superpoint approach to Lie supergroups.)

**Lemma 4.1.** Let $\mathcal{G}$ be a Lie supergroup with multiplication $\mu^{\mathcal{G}}$, and the vector field $X$ as above. Then

(i) the induced vector field $\tilde{X}$ on the underlying manifold $G \times T_eG$ is given as

$$\tilde{X}(g,\xi) = (\xi^k(g), 0) \quad \forall (g, \xi) \in G \times T_eG,$$

(ii) the (even) vector fields $\tilde{X}$ and $X$ are complete.

**Proof.** (i) For $k \geq 0$, let $\sigma_X(\mathbb{R}^{0|k})$ be the section of $T(\mathcal{G}(\mathbb{R}^{0|k})) \times T(T_e\mathcal{G}(\mathbb{R}^{0|k})) \to \mathcal{G}(\mathbb{R}^{0|k}) \times T_e\mathcal{G}(\mathbb{R}^{0|k})$ induced by $\sigma_X$, and let $X^k$ be the corresponding derivation on $\mathcal{G}(\mathbb{R}^{0|k}) \times T_e\mathcal{G}(\mathbb{R}^{0|k})$. Since $\mathcal{G}(\mathbb{R}^{0|k}) \times (T_e\mathcal{G})(\mathbb{R}^{0|k})$ is an ungraded manifold,

$$\sigma_X(\mathbb{R}^{0|k})(g, \xi) = (T\mu^{\mathcal{G}} \circ (\sigma_0 \times i_\xi) \circ (g \times \xi), 0)$$

$$= (T\mu^{\mathcal{G}} \circ (0 \times \xi), 0)$$

$$= (T\mu^{\mathcal{G}})(0, \xi), 0)$$

$$= (T\mu^{\mathcal{G}})(0, (\xi), 0),$$

where $\mu^{\mathcal{G}}$ is the multiplication on $\mathcal{G}(\mathbb{R}^{0|k})$ and $\mu^{\mathcal{G}}$ is the left-multiplication by the element $g$ of the group $\mathcal{G}(\mathbb{R}^{0|k})$. We conclude that $\sigma_X(\mathbb{R}^{0|k})(g, \xi)$ (or equivalently $X^k_{(g, \xi)}$) corresponds to $(\xi^L(g), 0)$, where $\xi^L$ is the unique left-invariant vector field on $\mathcal{G}(\mathbb{R}^{0|k})$ such that its value in $e$ is $\xi$. (Observe that $\mathcal{G}(\mathbb{R}^{0|k})$ is a classical Lie group and not only a group object in the category of supermanifolds, allowing us to argue “point-wise”.)

(ii) The flows of $X^k$ are simply given by $F^{X^k} : \mathbb{R} \times \mathcal{G}(\mathbb{R}^{0|k}) \times (T_e\mathcal{G})(\mathbb{R}^{0|k}) \to \mathcal{G}(\mathbb{R}^{0|k}) \times (T_e\mathcal{G})(\mathbb{R}^{0|k})$, $(t, g, \xi) \mapsto (g \exp^{\mathcal{G}(\mathbb{R}^{0|k})}(t\xi), \xi)$. All fields $X^k$ are thus complete, in particular this holds for $\tilde{X} = X^0$, the induced vector field on $G = \mathcal{G}(\mathbb{R}^{0|0})$. By Theorem 2.3, the flow $F^{X^k} : \mathbb{R} \times \mathcal{G} \times T_e\mathcal{G} \to \mathcal{G} \times T_e\mathcal{G}$ is then global as well, i.e. $X$ is complete.

**Definition 4.2.** Let $\mathcal{G} = (G, \mathcal{O}_{\mathcal{G}})$ be a Lie supergroup with multiplication $\mu$ and neutral element $e$, and with the even vector field $X$ and its flow morphism...
F = F^X as above. Then the “exponential morphism of G” is given by \( \exp^G = \text{proj}_1 \circ F \circ \text{inj}_{(1)} \times \{e\} \times T_eG : T_eG \to G \), where \( \text{proj}_1 : G \times T_eG \to G \) is the projection on the first factor. Diagrammatically, one has

\[
\begin{array}{ccc}
\mathbb{R} \times G \times T_eG & \cong & \{1\} \times \{e\} \times T_eG \\
\downarrow & & \downarrow \text{proj}_1 \\
T_eG & \xrightarrow{\exp^G} & G.
\end{array}
\]

**Theorem 4.3.** The exponential morphism \( \exp^G : T_eG \to G \) for a Lie supergroup \( G \) fulfills and is uniquely determined by the following condition: for all \( k \geq 0 \), \( \exp^G(\mathbb{R}^{0|k}) : T_eG(\mathbb{R}^{0|k}) \to G(\mathbb{R}^{0|k}) \) is the exponential map \( \exp^{\mathbb{G}}(\mathbb{R}^{0|k}) \) of the finite-dimensional, ungraded Lie group \( \mathbb{G}(\mathbb{R}^{0|k}) \).

**Proof.** Using the notations of Lemma 4.1, a straightforward calculation shows that the flow \( F^{X^k} \) of \( X^k \) on \((G \times T_eG)(\mathbb{R}^{0|k})\) is given as follows \( (t, (g, \xi)) \mapsto F^X \circ \text{inj}_k \circ F^X \circ \text{inj}_k \circ (g \times \xi) \) and, notably, we have \( F^{X^k} \circ \text{inj}_{(1,e)}(\xi) = F^X \circ \text{inj}_1 \circ (e \times \xi) = F^X \circ \text{inj}_{(1,e)} \circ \xi \). Hence

\[
\exp^{\mathbb{G}}(\mathbb{R}^{0|k})(\xi) = \text{proj}_1 \circ F^X \circ \text{inj}_{(1,e)}(\xi) = \text{proj}_1 \circ F^X \circ \text{inj}_1 \circ (e \times \xi) = \exp^G \circ \xi = (\exp^G(\mathbb{R}^{0|k}))(\xi).
\]

On the other hand, it is clear that the subcategory of superpoints with objects \( \{\mathbb{R}^{0|k} | k \geq 0\} \) generates the category of supermanifolds in the following sense: given two different morphisms \( \phi_1, \phi_2 : \mathcal{M} \to \mathcal{N} \) between supermanifolds, there exists a \( k \geq 0 \) and a morphism \( \psi : \mathbb{R}^{0|k} \to \mathcal{M} \) such that \( \phi_1 \circ \psi \neq \phi_2 \circ \psi \). Thus it follows that the family \( \{\exp^G(\mathbb{R}^{0|k}) | k \geq 0\} \) uniquely fixes \( \exp^G \). \( \square \)

(4.3) Part of our interest in the integration of supervector fields stemmed from the construction of a geodesic flow in \( \mathbb{M} \). Given a homogeneous (i.e., even or odd) Riemannian metric on a supermanifold \( \mathcal{M} \), the associated geodesic flow is, in fact, defined as the flow of an appropriate Hamiltonian vector field on its (co-)tangent bundle.

(4.4) An odd vector field \( X_1 \) on a supermanifold \( \mathcal{M} \) is called “homological” if \( X_1 \circ X_1 = \frac{b}{2}[X_1, X_1] = 0 \). Its flow is given by the following \( \mathbb{R}^{0|1} \)-action \( \Phi : \mathbb{R}^{0|1} \times \mathcal{M} \to \mathcal{M} \), \( \Phi^t(f) = f + \tau \cdot X_1(f) \), \( \forall f \in \mathcal{O}_{\mathcal{M}}(\mathcal{M}) \). This action can, of course, be extended to a (not almost-effective) \( \mathbb{R}^{1|1}, \mu_{a,b}) \)-action if and only if \( b = 0 \).

Typical examples arise as follows: let \( \mathbb{E} \to \mathcal{M} \) be a vector bundle over a classical manifold and \( T \) be an “appropriate” \( \mathbb{R} \)-linear operator on sections of \( \wedge \mathbb{E} \), then \( T \) yields a vector field on \( \Pi \mathbb{E} := (\mathcal{M}, \mathbb{E}^\infty_{\mathbb{E}}) \), the supermanifold...
associated to \( E \to M \) by the Batchelor construction. If \( E = TM \to M \), we have \( \Gamma_{\infty E^*} = \Omega^*_M(M) \), the sheaf of differential forms on \( M \), with its natural \( \mathbb{Z}/2\mathbb{Z} \)-grading. Taking \( T = d \), we get an odd vector field that is obviously homological. Taking \( T = t_\xi \), the contraction of differential forms with a vector field \( \xi \) on the (here classical) base manifold \( M \), we again get a homological vector field on \( \Pi TM \). Since \( t_\xi \circ t_\eta + t_\eta \circ t_\xi = 0 \), the vector space of all vector fields on \( M \) is realized as a commutative, purely odd sub Lie superalgebra of all vector fields on \( \Pi TM \). More generally, a section \( s \) of \( E \to M \) always gives rise to a contraction \( t_s : \Gamma_{\infty E^*}(M) \to \Gamma_{\infty E^*}(M) \) that is an odd derivation (i.e. an anti-derivation of degree -1 in more classical language). Furthermore, given two sections \( s \) and \( t \) of \( E \), the associated odd vector fields commute. In the article \( \mathbb{I} \) this construction is studied in the special case that \( E \) is the spinor bundle over a classical spin manifold \( M \).

(4.5) If \( G \) is a Lie group acting on a classical manifold \( M \), then the action can of course be lifted to an action on the total space of the tangent and the cotangent bundle of \( M \). The induced vector fields on \( \Pi TM \) are even and \( \xi \) in \( g = \text{Lie}(G) \), the Lie algebra of \( G \), acts on \( \mathcal{O}_{\Pi TM} \) by \( \mathcal{L}_\xi \), the Lie derivative with respect to the fundamental vector field on \( M \) associated to \( \xi \). Putting together these fields and the contractions constructed in Example (4.4), we get a Lie superalgebra with underlying vector space \( g \oplus g \), the first resp. second summand being the even resp. odd part. The commutators in \( g \oplus g \) are given as follows: \( [\mathcal{L}_\xi, \mathcal{L}_\eta] = \mathcal{L}_{[\xi, \eta]} \), \( [t_\xi, t_\eta] = 0 \) and \( [\mathcal{L}_\xi, t_\eta] = t_{[\xi, \eta]} \) for all \( \xi, \eta \in g \). In fact, the above can be interpreted as an action of the Lie supergroup \( \Pi TG \) on \( \Pi TM \).

The Lie algebra \( g \oplus g \) can be extended by a one-dimensional odd direction generated by the exterior derivative \( d \). The extended algebra \( g \oplus (g \oplus \mathbb{R} \cdot d) \), still a sub Lie superalgebra of \( \mathcal{T}_{\Pi TM}(M) \), has the following additional commutators:

\[
[\mathcal{L}_\xi, d] = 0 \quad \text{and} \quad [d, t_\xi] = \mathcal{L}_\xi \quad \text{for all} \quad \xi \in g.
\]

(4.6) If \( \mathcal{M} = \mathbb{R}^{1|1} \) with coordinates \((x, \xi)\), the vector field \( X_1 = \partial_x + \xi \partial_\xi \) is obviously odd and non-homological since \( X_1 \circ X_1 = \partial_x \). Direct inspection shows that the map \( \Phi : \mathbb{R}^{1|1} \times \mathcal{M} \to \mathcal{M}, \Phi^*(f) = f + \tau \cdot X_1(f) \) (compare Example (4.4)) does not fulfill \( \partial_\tau \circ \Phi^* = \Phi^* \circ X_1 \). Nevertheless, the trivial extension of \( \Phi \) to a morphism \( F : \mathbb{R}^{1|1} \times \mathcal{M} \to \mathcal{M} \) is the flow of \( X_1 \) in the sense of Theorem 3.3 fulfilling the initial condition \( \phi = \text{id}_\mathcal{M} \). We underline that this map is not an action of \( \mathbb{R}^{1|1} \). Upon extending \( X_1 \) to \( X := X_0 + X_1 \) with \( X_0 := \frac{1}{2}[X_1, X_1] = X_1 \circ X_1 \), we obtain by Theorem 3.3 an action of \((\mathbb{R}^{1|1}, \mu_{1,0})\) as the flow map of \( X \). Let us observe that the above vector field \( X_1 \) (and not \( X \)) is the prototype of what is called a “supersymmetry” in the physics literature (compare, e.g., [21] and the other relevant texts in these volumes.). More recently, the associated Lie supergroup structure on \( \mathbb{R}^{1|1} \) (and an analogous structure on \( \mathbb{R}^{2|1} \)) were introduced by S. Stolz and P. Teichner into their program to geometrize the cocycles of elliptic cohomology (compare

Documenta Mathematica 18 (2013) 519–545
Obviously, one can generalize this construction to $\mathbb{R}^{m|n}$ ($m, n \geq 1$) with coordinates $(x_1, \ldots, x_m, \xi_1, \ldots, \xi_n)$ by setting for $1 \leq k \leq m$, $1 \leq \alpha \leq n$

$$D_{\alpha,k} := \partial_{\xi_{\alpha}} + \xi_{\alpha} \cdot \partial_{x_k}.$$  

We then have $[D_{\alpha,k}, D_{\beta,l}] = \delta_{\alpha,\beta} \cdot (\partial_{x_k} + \partial_{x_l})$ and $[D_{\alpha,k}, D_{\beta)] = 0$. Taking $X_1 = D_{\alpha,k}$ and $X_0 = \partial_{x_k}$ we reproduce a copy of the preceding situation.

(4.7) The vector field $X = X_0 + X_1$ on $\mathcal{M} = \mathbb{R}^{1|1}$ with $X_0 = \partial_x + \xi \cdot \partial_{\xi}$ and $X_1 = \partial_{\xi} + \xi \cdot \partial_x$, already mentioned in the introduction, is a very simple example of an inhomogeneous vector field not generating any local $\mathbb{R}^{1|1}$-action, since, e.g., condition (iii) in Theorem 3.4 is violated. Thus integration of $X$ is only possible in the sense of Theorem 2.3, i.e. upon using the evaluation map. Let us observe that the sub Lie superalgebra $g$ of $T_M(M)$ generated by $X_0$ and $X_1$ since sub Lie superalgebras are by definition graded sub vector spaces, is four-dimensional with two even generators $Z, W$ and two odd generators $D, Q$ such that:

$Z$ is central, $[W, D] = Q$, $[W, Q] = D$, $D^2 = -Q^2 = Z$ and $[D, Q] = 0$. (This amounts in physical interpretation to the presence of two commuting supersymmetries $D$ and $Q$, generating the same supersymmetric Hamiltonian $Z$ plus an even symmetry commuting with the Hamiltonian and exchanging the supersymmetries $D$ and $Q$.)

5 Flow of a holomorphic vector field on a holomorphic supermanifold

In this section we extend our results to the holomorphic case. We will always denote the canonical coordinates on $\mathbb{C}^{1|1}$ by $z$ and $\xi$ and write $\partial_z$ resp. $\partial_{\xi}$ for $\frac{\partial}{\partial z}$ resp. $\frac{\partial}{\partial \xi}$. All “auxiliary” supermanifolds $S$ and morphisms having these as sources will be assumed to be holomorphic in this section.

**Definition 5.1.** Let $\mathcal{M} = (\mathcal{M}, \mathcal{O}_\mathcal{M})$ be a holomorphic supermanifold and $X$ a holomorphic vector field on $\mathcal{M}$ and $S$ a supermanifold with a morphism $\phi \in \text{Mor}(S, \mathcal{M})$ and $z_0$ in $\mathbb{C}$.

(1) A “flow for $X$ (with initial condition $\phi$ and with respect to $z_0$)” is an open sub supermanifold $V \subset \mathbb{C}^{1|1} \times S$, such that $\{z_0\} \times S \subset V$ (the bodies of $S$ and $V$) and such that for all $s$ in $S$, $(\mathbb{C} \times \{s\}) \cap V$ is connected, together with a morphism of holomorphic supermanifolds $F : V \to \mathcal{M}$ such that

$$(\text{inv}_{\mathbb{C}^{1|1}})^* \circ (\partial_{\xi} + \partial_z) \circ F^* = (\text{inv}_{\mathbb{C}^{1|1}})^* \circ F^* \circ X$$ and

$$F \circ \text{inv}_{\{z_0\} \times S} = \phi.$$  

Sometimes we call the supermanifold $V$ (or abusively its body $V$) the “flow domain” of $X$.
(2) A flow domain $V$ of a flow $(\mathcal{V}, F)$ for $X$ is called “fibrewise 1-connected (relative to the projection $\mathcal{V} \to S$)” (or “fibrewise 1-connected over $S$”) if for all $s$ in $S$, $(\mathcal{C} \times \{s\}) \cap V$ is connected and simply connected.

**Remark.** We avoid the term “complex supermanifold” here, since it is often used to describe supermanifolds that are, as ringed spaces, locally isomorphic to open sets $D \subset \mathcal{C}^{k}$ with structure sheaf $\mathcal{O}_{D} \otimes \mathcal{C}^{k}$. “Holomorphic supermanifolds” are of course locally isomorphic to open sets $D \subset \mathcal{C}^{k}$ with structure sheaf $\mathcal{O}_{D} \otimes \mathcal{C}^{k}$, where $\mathcal{O}_{D}$ denotes the sheaf of holomorphic functions on $D$.

Let us first give the holomorphic analogue of Lemma 2.1.

**Lemma 5.2.** Let $U \subset \mathcal{C}^{m|n}$ and $W \subset \mathcal{C}^{p|q}$ be superdomains, $X$ a holomorphic vector field on $W$ (not necessarily homogeneous), $\phi$ in $\text{Mor}(U, W)$ and $z_{0}$ in $\mathcal{C}$. Then

(i) it exists a holomorphic flow $(\tilde{V}, \tilde{F})$ for the reduced holomorphic vector field $\tilde{X}$ on $U$ with initial condition $\tilde{\phi}$ with respect to $z_{0}$ such that the flow domain $V \subset \mathcal{C} \times U$ is fibrewise 1-connected over $U$. Furthermore on every flow domain in the sense of Definition 5.1 the holomorphic flow is unique.

(ii) Let now $(\tilde{V}, \tilde{F})$ be a fibrewise 1-connected flow domain for $\tilde{X}$ over $U$. Then there exists a unique holomorphic flow $F : V \to W$ for $X$, with $V$ the open sub supermanifold of $\mathcal{C}^{1|1} \times U$ with body equal to $V$.

**Remark.** The example of the holomorphic vector field $X = (w^{2} + w^{3}\xi_{1}\xi_{2})\frac{\partial}{\partial w}$ on $W = \mathcal{C}^{1|2}$ with coordinates $(w, \xi_{1}, \xi_{2})$ shows that the condition of fibrewise 1-connectedness of $V$ is not only a technical assumption to our proof. The underlying vector field $\tilde{X} = w^{2}\frac{\partial}{\partial w}$ on $\mathcal{C}$, with initial condition $\tilde{\phi} = id : \mathcal{C} \to \mathcal{C}$ with respect to $z_{0} = 0$, can be integrated to the flow $\tilde{F} : V = \mathcal{C}^{2}\backslash\{z \cdot w = 1\} \to \mathcal{C}$, $\tilde{F}(z, w) = \frac{1}{1-zw}$ for $w \neq 0$ and $\tilde{F}(z, 0) = 0$. Obviously, for $w \neq 0$, $(\mathcal{C} \times \{w\}) \cap V$ is connected, but not simply connected. Direct inspection now shows that the flow $F$ of $X$ with initial condition $\phi = id$ and with respect to $z_{0} = 0$ cannot be defined on the whole of $V = (V, \mathcal{O}_{\mathcal{C}^{1|1} \times \mathcal{C}^{1|2}}|_{V})$.

**Proof of Lemma 5.2.** (i) The existence (and the stated unicity property) of a flow $(\tilde{V}, \tilde{F})$ for $\tilde{X}$, with $\{z_{0}\} \times U \subset \tilde{V} \subset \mathcal{C} \times U$ fulfilling the initial condition $\tilde{\phi}$ with respect to $z_{0} \in \mathcal{C}$ is of course a classical application of the existence of solutions of holomorphic ordinary differential equations (see, e.g., [5]). Upon reducing the size of $\tilde{V}$ we always find flow domains that are fibrewise 1-connected.

(ii) The induction procedure of the proof of Lemma 2.1 can be applied here upon recalling the following standard facts from the theory of holomorphic linear ordinary differential equations (compare, e.g., [5]):
Fact 1. Let \( \Omega \subset \mathbb{C} \) be open and 1-connected (i.e. connected and simply connected), and \( z_0 \in \Omega \). If \( A : \Omega \to \text{Mat}(N \times N, \mathbb{C}) \) and \( b : \Omega \to \mathbb{C}^N \) are holomorphic and \( \psi_0 \in \mathbb{C}^N \), then there exists a unique holomorphic map \( \psi : \Omega \to \mathbb{C}^N \) fulfilling
\[
\frac{\partial}{\partial z}\psi(z) = A(z)\psi(z) + b(z)
\]
such that \( \psi(z_0) = \psi_0 \).

Fact 2. Let \( \Omega \) and \( z_0 \) be as in Fact 1, and let \( P \) be a holomorphic manifold ("a parameter space"), and let \( A : \Omega \times P \to \text{Mat}(N \times N, \mathbb{C}) \), \( b : \Omega \times P \to \mathbb{C}^N \), as well as \( \psi_0 : P \to \mathbb{C}^N \) be holomorphic maps. Then there exists a unique holomorphic map \( \psi : \Omega \times P \to \mathbb{C}^N \) fulfilling
\[
\frac{\partial}{\partial z}\psi(z,x) = A(z,x)\psi(z,x) + b(z,x)
\]
such that \( \psi(z_0, x) = \psi_0(x) \), \( \forall x \in P \).

Obviously, to apply these facts in our context, we need the fibrewise 1-connectivity of the “underlying flow domain” \( V \) for \( \tilde{X} \).

Before stating and proving our central result in the holomorphic case, we give the following useful shorthand.

**Definition 5.3.** Let \( S \) be a supermanifold, \( z_0 \) in \( \mathbb{C} \) and \( N \subset \mathbb{C}^{1|1} \times S \) be an open sub supermanifold containing \( \{z_0\} \times S \). Then \( N^{z_0} \) is defined as the open sub supermanifold of \( N = (N, \mathcal{O}_N) \) whose body equals \( \bigcup_{s \in S} ((\mathbb{C} \times \{s\}) \cap N)^{(z_0, s)} \), where \( ((\mathbb{C} \times \{s\}) \cap N)^{(z_0, s)} \) is the connected component of \( (\mathbb{C} \times \{s\}) \cap N \) containing \( (z_0, s) \).

**Remark.** A flow domain \( V \) in the sense of Definition 5.1 is always open and contains \( \{z_0\} \times S \). Furthermore for all \( s \) in \( S \) the section \( (\mathbb{C} \times \{s\}) \cap V \) is connected. The preceding definition will in fact be useful for discussing intersections of flow domains in the next theorem.

**Theorem 5.4.** Let \( M \) be a holomorphic supermanifold and \( X \) a holomorphic vector field on \( M \), and let \( S \) be a holomorphic supermanifold with a holomorphic morphism \( \psi : S \to M \), and \( z_0 \in \mathbb{C} \). Then

(i) there exists a flow \((V, \tilde{F})\) for the reduced vector field \( \tilde{X} \) with initial condition \( \phi \) with respect to \( z_0 \) such that the flow domain \( V \subset \mathbb{C} \times S \) is fibrewise 1-connected over \( S \),

(ii) if \((V, \tilde{F})\) is as in (i), then there exists a unique flow for \( X \) with initial condition \( \phi \) with respect to \( z_0 \), \( F : V \to M \), where \( V \subset \mathbb{C}^{1|1} \times S \) is the open sub supermanifold with body \( V \).
(iii) if \((V_1, F_1)\) and \((V_2, F_2)\) are two flows for \(X\), both with initial condition \(\phi\) with respect to \(z_0\), then \(F_1 = F_2\) on the flow domain \((V_1 \cap V_2)^{z_0}\).

(iv) there exists maximal flow domains for \(X\) and the germs of their flows coincide on \(\{z_0\} \times S\).

**Proof.** (i) and (ii). It easily follows from Lemma 5.2 that \(S\) can be covered by open sub supermanifolds \(\{U^\alpha | \alpha \in A\}\) such that \(X|_{U^\alpha}\) has a holomorphic flow with initial condition \(\phi|_{U^\alpha}\) with respect to \(z_0\), \(F^\alpha : V^\alpha = \Delta_{r_\alpha}(z_0) \times C^{01} \times U^\alpha \to M\), where \(r_\alpha > 0\), and for \(r > 0\), \(\Delta_r(z_0)\) is the open disc of radius \(r\) centred in \(z_0\). Since \(F^\alpha = F^\beta\) on \(V^\alpha \cap V^\beta\) by the unicity part of Lemma 5.2, we can glue these flows to obtain \(\bigcup_{\alpha \in A} V^\alpha \to M\), a flow for \(X\) on \(M\) with initial condition \(\phi\) with respect to \(z_0\). Obviously, the “fibres” \((C \times \{s\}) \cap V\) are 1-connected for all \(s\) in \(S\), i.e., the flow domain \(V\) is fibrewise 1-connected over \(S\).

Note that if we have a flow \(\tilde{F}\) for the reduced vector field \(\tilde{X}\) on a flow domain \(V\) that is fibrewise 1-connected over \(S\), then part (ii) of Lemma 5.2 yields a flow for \(X\) defined on \(V = C^{11} \times S\).

(iii) The body of \((V_1 \cap V_2)^{z_0}\) has as a strong deformation retract the body of \(\{z_0\} \times S\). Without loss of generality we can assume that \(S\) and thus \((V_1 \cap V_2)^{z_0}\) are connected. The local unicity in Lemma 5.2 together with the identity principle for holomorphic morphisms of holomorphic supermanifolds imply that \(F_1 = F_2\) on \((V_1 \cap V_2)^{z_0}\).

(iv) By Zorn’s lemma we get maximal flow domains and by part (iii) the corresponding flows coincide near \(\{z_0\} \times S\). □

**Remarks.** (1) The non-unicity of maximal flow domains for holomorphic vector fields is a well-known phenomenon already in the ungraded case. A simple example for this is the vector field \(X\) on \(C^*\) such that \(X(w) = \frac{1}{w} \frac{dw}{dx}\) for all \(w\) in \(C^*\).

(2) Given the above theorem, the analogues of Lemma 3.1, Proposition 3.3, and Theorem 3.4 can now without difficulty be proven to hold for holomorphic supermanifolds.

PROJECTIVE VARIETIES
WITH BAD SEMI-STABLE REDUCTION AT 3 ONLY

TO I. R. SHAFAREVICH, ON THE OCCASION OF HIS 90TH BIRTHDAY

VICTOR ABRASHKIN

Received: April 30, 2013
Communicated by Peter Schneider

Abstract. Suppose \( F = W(k)[1/p] \) where \( W(k) \) is the ring of Witt vectors with coefficients in algebraically closed field \( k \) of characteristic \( p \neq 2 \). We construct integral theory of \( p \)-adic semi-stable representations of the absolute Galois group of \( F \) with Hodge-Tate weights from \( [0, p) \). This modification of Breuil’s theory results in the following application in the spirit of the Shafarevich Conjecture. If \( Y \) is a projective algebraic variety over \( \mathbb{Q} \) with good reduction modulo all primes \( l \neq 3 \) and semi-stable reduction modulo 3 then for the Hodge numbers of \( Y_\mathbb{C} = Y \otimes_\mathbb{Q} \mathbb{C} \), one has \( h^2(Y_\mathbb{C}) = h^{1,1}(Y_\mathbb{C}) \).

2010 Mathematics Subject Classification: 11S20, 11G35, 14K15
Keywords and Phrases: \( p \)-adic semi-stable representations, Shafarevich Conjecture

Introduction
Everywhere in the paper \( p \) is a fixed prime number, \( p \neq 2 \), \( k \) is algebraically closed field of characteristic \( p \), \( F \) is the fraction field of the ring of Witt vectors \( W(k) \), \( \bar{F} \) is a fixed algebraic closure of \( F \) and \( \Gamma_F = \text{Gal}(\bar{F}/F) \) is the absolute Galois group of \( F \).
Suppose \( Y \) is a projective algebraic variety over \( \mathbb{Q} \). Denote by \( Y_\mathbb{C} \) the corresponding complex variety \( Y \otimes_\mathbb{Q} \mathbb{C} \). For integers \( n, m \geq 0 \), set \( h^n(Y_\mathbb{C}) = \dim_\mathbb{C} H^n(Y_\mathbb{C}, \mathbb{C}) \) and \( h^{n,m}(Y_\mathbb{C}) = \dim_\mathbb{C} H^n(\Omega^m_{Y_\mathbb{C}}) \).
The main result of this paper can be stated as follows.

Theorem 0.1. If \( Y \) has semi-stable reduction modulo 3 and good reduction modulo all primes \( l \neq 3 \) then \( h^2(Y_\mathbb{C}) = h^{1,1}(Y_\mathbb{C}) \).
Remind that a generalization of the Shafarevich Conjecture about the non-existence of non-trivial abelian varieties over $\mathbb{Q}$ with everywhere good reduction was proved by Fontaine [16] and the author [2], and states that

\[ h^1(Y_C) = h^3(Y_C) = 0, \quad h^2(Y_C) = h^{1,1}(Y_C) \]

if $Y$ has everywhere good reduction. (The Shafarevich Conjecture appears then as the equality $h^1(Y_C) = 0$.) This result became possible due to the following two important achievements of Fontaine’s theory of $p$-adic crystalline representations:

— the Fontaine-Messing theorem relating etale and de Rham cohomology of smooth proper schemes over $W(k)$ in dimensions $[0, p)$, [15] (it was later proved by Faltings in full generality, [12]);

— the Fontaine-Laffaille integral theory of crystalline representations of $\Gamma_F$ with Hodge-Tate weights from $[0, p-2]$, [13].

Note that the Fontaine-Laffaille theory works essentially for Hodge-Tate weights from $[0, p)$ but does not give all Galois invariant lattices in the corresponding crystalline representations. Nevertheless, this theory admits improvement developed by the author in [1]. As a result, there was obtained a suitable integral theory for the case of Hodge-Tate weights from $[0, p)$, which allowed us to prove some extras to statements (0.1), in particular, that modulo the Generalized Riemann Hypothesis one has $h^4(Y_C) = h^{2,2}(Y_C)$.

Since that time there was a huge progress in the study of semi-stable $p$-adic representations. Tsuji [23] proved a semi-stable case of the relation between etale and crystalline cohomology and Breuil [5, 6] developed an analogue of the Fontaine-Laffaille theory in the context of semi-stable representations (even for ramified basic fields). The papers [4] and [21] studied the problem of the existence of abelian varieties over $\mathbb{Q}$ with only one prime of bad semi-stable reduction. Note that the progress in this direction is quite restrictive because our knowledge of algebraic number fields with prescribed ramification at a given prime number $p$ (and unramified outside $p$) is very far from to be complete.

Theorem 0.1 represents an exceptional situation where the standard tools: the Odlyzko estimates of the minimal discriminants of algebraic number fields and the modern computing facilities (SAGE) are sufficient to resolve upcoming problems. In addition, the proof of this theorem requires a modification of Breuil’s theory to work with semi-stable representations of $\Gamma_F$ with Hodge-Tate weights from $[0, p)$.

The structure of this paper can be described as follows.

In Section 1 we introduce the category $\mathcal{L}_\psi^*$ of filtered ($\varphi, N$)-modules over $\mathcal{W}_1 := k[[u]]$. This is a special pre-abelian category, that is an additive category with kernels, cokernels and sufficiently nice behaving short exact sequences. Note that such categories play quite appreciable role in all our constructions. In Section 2 we construct the functor $\mathcal{V}^*$ from $\mathcal{L}_\psi^*$ to the category of $\mathbb{F}_p[\Gamma_F]$-modules $\mathbb{M}_\psi$ by introducing a “truncated” version of Fontaine’s ring of semi-stable periods $A_{st}$. The functor $\mathcal{V}^*$ is not fully faithful but by taking into account the maximal etale subobjects of filtered modules from $\mathcal{L}_\psi^*$ we define a
modification $CV^*$ of $V^*$. This functor gives already a fully faithful functor from $L^*$ to the category of cofiltered $\Gamma_F$-modules $CM\Gamma_F$. In Section 3 we give an interpretation of Breuil’s theory in terms of $W := W(k[[u]])$-modules (Breuil worked with modules over the divided powers envelope of $W$) by introducing the category of filtered $(\varphi,N)$-modules $L^{ft}$ over $W$. The advantage of this construction is that the objects of this category appear as strict subquotients of $p$-divisible groups in suitable pre-abelian category. This allows us to use devissage despite that all involved categories are not abelian. We also introduce the subcategories $L^{u,ft}$ and, resp., $L^{m,ft}$ of unipotent and, resp., multiplicative objects in $L^{ft}$ and prove that any $L \in L^{ft}$ is a canonical extension

\[(0.2) \quad 0 \to L^u \to L \to L^m \to 0\]

of a multiplicative object $L^m$ by a unipotent object $L^u$. In Section 4 we study Breuil’s functor $V^{ft} : L^{ft} \to M\Gamma_F$ in the situation of Hodge-Tate weights from $[0,p)$. We show that on the subcategory $L^{u,ft}$ this functor is still fully faithful by proving that on the subcategory of killed by $p$ unipotent objects the functors $V^{ft}$ and $V^*$ coincide. Then we show that for any killed by $p$ object $L$ of $L^{ft}$, the functor $V^{ft}$ transforms the standard short exact sequence (0.2) into a short exact sequence in $M\Gamma_F$, which admits a functorial splitting. This splitting is used then to construct a modified version $\tilde{CV}^{ft} : L^{ft} \to CM\Gamma_F$ of $V^{ft}$, which is already fully faithful. This gives us an efficient control on all Galois invariant lattices of semi-stable representations with weights from $[0,p)$. Especially, we have an explicit description of all killed by $p$ subquotients of such lattices and the corresponding ramification estimates. Finally, in Section 5 we give a proof of Theorem 0.1 following the strategy from [2].

Essentially, we obtain the following result: if $V$ is a 3-adic representation of $\Gamma_{\overline{Q}} = Gal(\overline{Q}/Q)$ which is unramified outside 3 and is semi-stable at 3 then there is a $\Gamma_{\overline{Q}}$-equivariant filtration by $\mathbb{Q}_3$-subspaces $V = V_0 \supset V_1 \supset V_2 \supset V_3 = 0$ such that for $0 \leq i \leq 2$, the $\Gamma_{\overline{Q}}$-module $V_i/V_{i+1}$ is isomorphic to the product of finitely many copies of the Tate twist $\mathbb{Q}_3(i)$. If $V = H^2_{et}(Y_{\mathbb{C}}, \mathbb{Q}_3)$ then looking at the eigenvalues of the Frobenius morphisms of reductions modulo $l \neq 3$, we obtain that $V = V_1$ and $V_2 = 0$, and this implies that $h^2(Y_{\mathbb{C}}) = h^{1,1}(Y_{\mathbb{C}})$

Note that our construction of the modification of Breuil’s functor gives automatically the modification of the Fontaine-Laffaille functor, which essentially coincides with the modification constructed in [1]. It is worth mentioning that switching from Breuil’s $S$-modules to $W$-modules means moving in the direction of Kisin’s approach [18] and recent approach to integral theory of $p$-adic representations by Liu [19, 20]. It would be also very interesting to study the opportunity to modify Breuil’s functor over ramified base [8, 9] to the case of Hodge-Tate weights from $[0,p)$. Finally, mention quite surprising matching of the ramification estimates for semi-stable representations and the Leopoldt conjecture for the field $Q(\sqrt[3]{3}, \zeta_9)$, cf. Section 5.

Acknowledgements. The author is very grateful to Shin Hattori for numerous and helpful discussions.
1. The categories $\mathcal{L}_0^*, \mathcal{L}_1^*, \mathcal{L}_2^*$

Remind that $k$ is algebraically closed field of characteristic $p > 2$. Let $W = W(k)[[x]]$, where $W(k)$ is the ring of Witt vectors with coefficients in $k$ and $u$ is an indeterminate. Denote by $\sigma$ the automorphism of $W(k)$ induced by the $p$-th power map on $k$ and agree to use the same symbol for its continuous extension to $W$ such that $\sigma(u) = u^p$. Denote by $N : W \to W$ the continuous $W(k)$-linear derivation such that $N(u) = -u$.

We shall often use below the following statement.

**Lemma 1.1.** Suppose $L$ is a finitely generated $W$-module and $A$ is a $\sigma$-linear operator on $L$. Then the operator $id_L - A$ is epimorphic. If, in addition, $A$ is nilpotent then $id_L - A$ is bijective.

**Proof.** Part b) is obvious. In order to prove a) notice first that we can replace $L$ by $L/uL$ and, therefore, assume that $L$ is a finitely generated $W(k)$-module. Clearly, it will be enough to consider the case $pL = 0$. Then there is a decomposition of $k$-vector spaces $L = L_1 \oplus L_2$, where $A$ is invertible on $L_1$ and nilpotent on $L_2$. It remains to note that $L_1 = L_0 \otimes_{\mathbb{F}_p} k$, where $L_0$ is a finite dimensional $\mathbb{F}_p$-vector space such that $A|_{L_0} = id$. The existence of $L_0$ is a standard fact of $\sigma$-linear algebra: if $s = \dim_k L_1$ and $A \in M_s(k)$ is a matrix of $A|_{L_1}$ in some $k$-basis of $L_1$ then $L_0 = \{(x_1, \ldots, x_s) \in k^s \mid (x_1^p, \ldots, x_s^p)A = (x_1, \ldots, x_s)\}$; the $\mathbb{F}_p$-linear space $L_0$ has dimension $s$ because the corresponding equations determine an etale algebra of rank $p^s$ over algebraically closed field $k$.

**Remark.** In above Lemma and everywhere below we use the following agreement: $A$ is nilpotent on $L$ iff it is “topologically nilpotent”, i.e. $\bigcap_n A^n(L) = 0$.

1.1. Definitions and general properties. Let $W_1 = W/pW$ with induced $\sigma$, $\varphi$ and $N$.

**Definition.** The objects of the category $\mathcal{L}_0^*$ are the triples $L = (L, F(L), \varphi)$, where

- $L$ and $F(L)$ are $W_1$-modules such that $L \supset F(L)$;
- $\varphi : F(L) \to L$ is a $\sigma$-linear morphism of $W_1$-modules; (Note that $\varphi(F(L))$ is a $\sigma(W_1)$-submodule in $L$.)

If $L_1 = (L_1, F(L_1), \varphi)$ is also an object of $\mathcal{L}_0^*$, then the morphisms $f \in \text{Hom}_{\mathcal{L}_0^*}(L_1, L)$ are given by $W_1$-linear maps $f : L_1 \to L$ such that $f(F(L_1)) \subset F(L)$ and $f\varphi = \varphi f$.

**Definition.** The objects of the category $\mathcal{L}_1^*$ are the quadruples $L = (L, F(L), \varphi, N)$, where

- $(L, F(L), \varphi)$ is an object of the category $\mathcal{L}_0^*$;
- $N : L \to L/u^nL$ is a $W_1$-differentiation, i.e. for all $w \in W_1$ and $l \in L$, $N(wl) = N(w)(l \mod u^nL) + wN(l)$;
• if \( L_1 = (L_1, F(L_1), \varphi, N) \) is another object of \( L^*_0 \) then the morphisms \( \text{Hom}_{L^*_0}(L_1, L) \) are given by \( f: (L_1, F(L_1), \varphi) \to (L, F(L), \varphi) \) from \( L^*_0 \) such that \( fN = NF \). (We use the same notation \( f \) for the reduction of \( f \) modulo \( u^{2p}L \).

The categories \( L^*_0 \) and \( L^*_1 \) are additive.

**Definition.** The category \( L^*_0 \) is a full subcategory of \( L^*_1 \) consisting of the objects \( L = (L, F(L), \varphi) \) such that

- \( L \) is a free \( W_1 \)-module of finite rank;
- \( F(L) \supset u^{p-1}L \);
- the natural embedding \( \varphi(F(L)) \subset L \) induces the identification \( \varphi(F(L)) \otimes_{\sigma(W_1)} W_1 = L \).

Note that \( \varphi \) induces a map \( F(L)/u^{2p}L \to L/u^{2p}L \); use that \( u^{2p}L \subset u^{p+1}F(L) \subset u^2F(L) \) and \( \varphi(uF(L)) \subset u^{2p}L \). We shall denote this map by the same symbol \( \varphi \).

**Definition.** The category \( L^*_1 \) is a full subcategory of \( L^*_0 \) consisting of the objects \( L = (L, F(L), \varphi, N) \) such that

- \( (L, F(L), \varphi) \in L^*_0 \);
- for all \( l \in F(L), uN(l) \in F(L) \mod u^{2p}L \) and \( N(\varphi(l)) = \varphi(uN(l)) \).

The categories \( L^*_0 \) and \( L^*_1 \) are additive.

In the case of objects \( (L, F(L), \varphi, N) \) of \( L^*_1 \) the morphism \( N \) can be uniquely recovered from the \( W_1 \)-differentiation \( N_1 = N \mod u^pL \) due to the following property.

**Proposition 1.2.** Suppose \( (L, F(L), \varphi) \in L^*_0 \) and \( N_1 : L \to L/u^pL \) is a \( W_1 \)-differentiation such that for any \( m \in F(L), uN_1(m) \in F(L) \mod u^pL \) and \( N_1(\varphi(m)) = \varphi(uN_1(m)) \). Then there is a unique \( W_1 \)-differentiation \( N : L \to L/u^{2p}L \) such that \( N \mod u^p = N_1 \) and \( (L, F(L), \varphi, N) \in L^*_1 \).

**Proof.** Choose a \( W_1 \)-basis \( m_1, \ldots, m_s \) of \( F(L) \). Then \( l_1 = \varphi(m_1), \ldots, l_s = \varphi(m_s) \) is a \( W_1 \)-basis of \( L \) and a \( \sigma(W_1) \)-basis of \( \varphi(F(L)) \).

Let \( N(l_i) := \varphi(uN_1(m_i)) \in L/u^{2p}L \), where \( N_1(m_i) \) are some lifts of \( m_i \) to \( L/u^{2p}L \). Clearly, the elements \( N(l_i) \in \varphi(F(L)) \subset L/u^{2p}L \) are well-defined (use that \( u^{p+1}L \subset u^{2p}L \).

For any \( l = \sum w_i l_i \in L \), let \( N(l) := \sum w_i N(l_i) + \sum w_i N(l_i) \). Then \( N : L \to L/u^{2p}L \) is a \( W_1 \)-differentiation and \( N \mod u^p = N_1 \). Clearly, \( N \) is the only candidate to satisfy the requirements of our Proposition.

Now suppose \( m = \sum w_i m_i \in F(L) \) with all \( w_i \in W_1 \). Then \( N(\varphi(m)) = \sum w_i \sigma(w_i) l_i + \sum w_i \sigma(w_i) uN(m_i) \).

On the other hand, \( \varphi(uN(m)) \) equals

\[
\sum w_i \sigma(N(w_i)) l_i + \sum w_i \varphi(w_i uN(m_i)) = \sum w_i \sigma(w_i) l_i \mod u^{2p}
\]

because all \( \sigma(N(w_i)) \in u^p \sigma(W_1) \).

The proposition is proved.
Remark. By above Proposition in the definition of objects of $\mathcal{L}^*$ one can replace $N : L \rightarrow L/u^p L$ by $N_1 = N \mod u^p L$ and use $N$ as a unique extension of $N_1$ if necessary. An example of the situation where we do need to extend $N_1$ is described in Proposition 1.3 below. Another situation is related to the definition of the truncated version $R^p_\ast$ of $A_\ast$ in Subsection 2. Here we need $N$ to be defined modulo some smaller module than $u^p L$, e.g. $u^{p+1} L$. Our choice was done in favour of the module $u^p L$ because it is the smallest possible module where the definition of $N$ makes sense.

Proposition 1.3. $\mathcal{L}_0^*$ and $\mathcal{L}^*$ are pre-abelian categories (cf. Appendix A for the concept of pre-abelian category).

Proof. Suppose $\mathcal{S}$ is an additive category and $f \in \text{Hom}_\mathcal{S}(A, B)$, $A, B \in \mathcal{S}$. Then $i \in \text{Hom}_\mathcal{S}(K, A)$ is a kernel of $f$ if for any $D \in \mathcal{S}$, the sequence of abelian groups

$$0 \rightarrow \text{Hom}_\mathcal{S}(D, K) \xrightarrow{i} \text{Hom}_\mathcal{S}(D, A) \xrightarrow{f} \text{Hom}_\mathcal{S}(D, B)$$

is exact. Similarly, $j \in \text{Hom}_\mathcal{S}(B, C)$, $B, C \in \mathcal{S}$, is a cokernel of $f$ if for any $D \in \mathcal{S}$, the sequence

$$0 \rightarrow \text{Hom}_\mathcal{S}(C, D) \xrightarrow{j} \text{Hom}_\mathcal{S}(B, D) \xrightarrow{f} \text{Hom}_\mathcal{S}(A, D)$$

is exact.

Let $FF_{\mathcal{W}_1}$ be the category of free $\mathcal{W}_1$-modules with filtration. This category is pre-abelian. More precisely, consider the objects $\mathcal{L} = (L, F(L))$ and $\mathcal{M} = (M, F(M))$ in $FF_{\mathcal{W}_1}$ and let $f \in \text{Hom}_{FF_{\mathcal{W}_1}}(\mathcal{L}, \mathcal{M})$. Then $\text{Ker}_{FF_{\mathcal{W}_1}}f$ is a natural embedding $i_C : K = (K, F(K)) \rightarrow \mathcal{L}$, where $K = \text{Ker}(f : L \rightarrow M)$ and $F(K) = K \cap F(L)$. The cokernel $\text{Coker}_{FF_{\mathcal{W}_1}}f$ of $\text{Ker}_{FF_{\mathcal{W}_1}}f$ appears as a natural projection $j_{\mathcal{L}} : \mathcal{L} \rightarrow \mathcal{L}' = (L', F(L'))$, where $L' = f(L)$ and $F(L') = f(F(L))$. Similarly, $\text{Ker}_{FF_{\mathcal{W}_1}}f$ is a natural projection $j_M : \mathcal{M} \rightarrow \mathcal{C} = (C, F(C))$, where $C = (M/L')/(M/L)_{\text{tor}}$ and $F(C) = j_M(F(M))$. Then the image $\text{Im}_{FF_{\mathcal{W}_1}}f = \text{Ker}_{FF_{\mathcal{W}_1}}(\text{Coker}_{FF_{\mathcal{W}_1}}f)$ is a natural embedding $M' = (M', F(M')) \rightarrow \mathcal{M}$, where $M'$ is the kernel of $j_M$ and $F(M') = F(M) \cap M'$. As usually, there is a natural map $\mathcal{L}' \rightarrow M'$ induced by $L' \subset M'$. Note that $M/M' = C$ is free and $M'/L'$ is torsion $\mathcal{W}_1$-modules and these properties completely characterize $M'$ as a $\mathcal{W}_1$-submodule of $M$.

Now suppose $\mathcal{L} = (L, F(L), \varphi)$, $\mathcal{M} = (M, F(M), \varphi)$ are objects of $\mathcal{L}_0^*$ and $f \in \text{Hom}_{\mathcal{L}_0^*}(\mathcal{L}, \mathcal{M})$. Use the obvious forgetful functor $\mathcal{L}_0^* \rightarrow FF_{\mathcal{W}_1}$ and the same notation for the corresponding images of $\mathcal{L}$, $\mathcal{M}$ and $f$. Show that $K = \text{Ker}_{FF_{\mathcal{W}_1}}f$ and $\mathcal{C} = \text{Coker}_{FF_{\mathcal{W}_1}}f$ have the natural structures of objects of $\mathcal{L}_0^*$ and with respect to this structure they become the kernel and, resp, cokernel of $f$ in $\mathcal{L}_0^*$. Indeed, $u^{p-1} K = u^{p-1} L \cap K \subset F(L) \cap K = F(K) = \text{Ker}(f : F(L) \rightarrow F(M))$. Therefore, $\varphi(F(K)) \subset K \cap \varphi(F(L))$ and there is a natural embedding $\iota : \varphi(F(K)) \otimes_{\mathcal{W}_1} \mathcal{W}_1 \subset K$. On the one hand,

$$\text{rk}_{\mathcal{W}_1}(\varphi(F(K))) = \text{rk}_{\mathcal{W}_1} F(K) = \text{rk}_{\mathcal{W}_1} K.$$
On the other hand, $F(L)/F(K) \subset L/K = L'$ have no $W_1$-torsion. This implies that the quotient $\varphi(F(L))/\varphi(F(K))$ has no $\sigma W_1$-torsion and the factor of $L = \varphi(F(L))$, $\mathcal{W}_1$ by $\varphi(F(K)) \otimes_{\sigma W_1} W_1$ also has no $W_1$-torsion. So, $i$ becomes the equality $\varphi(F(K)) \otimes_{\sigma W_1} W_1 = K$ and $K = (K, F(K), \varphi) = \text{Ker} F \varphi$. 

The above description of $\text{Ker} F \varphi$ implies that $u^{p-1} L' \subset F(L')$, $\varphi(F(L')) = \varphi(F(M))/\varphi(F(K))$ and $L' = \varphi(F(L')) \otimes_{\sigma W_1} W_1$. In other words, $L' = (L', F(L'), \varphi) \in \mathcal{L}_L$. 

Now note that for $M' = (M', F(M'))$, we have 

$$u^{p-1} M' = (u^{p-1} M) \cap M' \subset F(M') \cap M' = F(M')$$

and, therefore, $F(M')/F(L')$ is torsion $W_1$-module and 

- $(\varphi(F(M')) \otimes_{\sigma W_1} W_1)/L'$ is torsion $W_1$-module; 

On the other hand, $F(M)/F(M') = F(C)$ is torsion free $W_1$-module. This implies that $\varphi(F(M))/F(M')$ is torsion free $\sigma W_1$-module and, therefore, 

- $M/(\varphi(F(M')) \otimes_{\sigma W_1} W_1)$ is torsion free $W_1$-module.

The above two conditions completely characterize $M'$ as a submodule of $M$. Therefore, $\varphi(F(M')) \otimes_{\sigma W_1} W_1 = M'$, $M' = (M', F(M'), \varphi) \in \mathcal{L}_L$ and $(M/M', F(M))/F(M')$, $\varphi = (C, F(C), \varphi) = \mathcal{C} \in \mathcal{L}_L$. Now a formal verification shows that $\mathcal{C} = \text{Coker} F \varphi$.

Again $\text{Coim} F \varphi = (L', F(L'), \varphi)$ and $\text{Im} F \varphi = (M', F(M'), \varphi)$ together with their natural embedding $\text{Coim} F \varphi \hookrightarrow \text{Im} F \varphi$ in $\mathcal{L}_L$. As a matter of fact, these two objects of the category $\mathcal{L}_L$ do not differ very much due to the following Lemma.

**Lemma 1.4.** $\varphi(F(L')) \supset u^p \varphi(F(M'))$ (and, therefore, $L' \supset u^p M'$).

**Proof of Lemma.** Otherwise, there is an $l \in \varphi(F(L')) \setminus u^p \varphi(F(L'))$ such that $l \in u^{2p} \varphi(F(M'))$.

Form the sequence $l_n \in L'$ such that $l_1 = l$ and for all $n \geq 2$, $l_{n+1} = \varphi(u^n l_n)$, where $a_n \geq 0$ is such that $u^{a_n} l_n \in F(L') \setminus u F(L')$. Clearly, all $l_n \notin u F(L') \supset u^p L'$. 

On the other hand, $l \in u^{2p} \varphi(F(M')) \subset u^{p+1} F(M')$ and, therefore, for all $n \geq 1$, $l_n \in \varphi(u^{2p} M') \subset u^{p+1} u^p M'$. So, for $n \gg 0$, $l_n \in u^p L'$. The contradiction. \qed

Now suppose $\mathcal{L} = (L, F(L), \varphi, N)$ and $M = (M, F(M), \varphi, N)$ are objects of $\mathcal{L}_L$, and $f \in \text{Hom}_{\mathcal{L}_L} (L, M)$. Prove that the kernel $(K, F(K), \varphi)$ and the cokernel $(C, F(C), \varphi)$ of $f$ in the category $\mathcal{L}_L$ have a natural structure of objects of the category $\mathcal{L}_L^*$. 

Clearly, $\mathcal{N}(K) \subset \text{Ker} f \mod u^{2p} : L/u^{2p} L \rightarrow M/u^{2p} M$. The above Lemma 1.4 implies that $u^p L' \supset u^p M'$ and we obtain the following natural maps 

$$L'/u^p L' \xrightarrow{\alpha} L'/u^{2p} M' \xrightarrow{\beta} M'/u^{2p} M' \xrightarrow{\gamma} M/u^{2p} M.$$ 

Note that $\alpha$ is epimorphic but $\beta$ and $\gamma$ are monomorphic. This implies that $\mathcal{N}(K) \subset \text{Ker} F \varphi L/u^p L \rightarrow L'/u^p L'$ and $\mathcal{N}(K) \mod u^p L \subset \text{Ker} L/u^p L \rightarrow L'/u^p L' = K/u^p K$.
Therefore, by Proposition 1.2, \( N \) (as a unique lift of \( N_1 = N \ mod \ u^p \)) maps \( K \) to \( K/u^pK \) and \( (K, F(K), \varphi, N) \in \mathcal{L}^* \).

The above property of Ker\( L \), \( f \) implies that \( N(L') \subset L'/u^pL' \). Now use that \( u^pM' \subset L' \), \( u^pL' \subset u^pM' \) and \( N(u^pM') \subset u^pM/u^pM \) to deduce that

\[
N(u^pM') \subset (L'/u^pM') \cap (u^pM/u^pM) = u^pM'/u^pM'.
\]

So, \( N \ mod \ u^p \) maps \( M' \) to \( M'/u^pM' \) and again by Proposition 1.2 \( N(M') \subset M'/u^pM' \). This means that the kernel of the above constructed Coker\( f : (M, F(M), \varphi) \rightarrow (C, F(C), \varphi) \) is provided with the structure of object of the category \( \mathcal{L}^* \). Therefore, \( N \) induces the map \( N : C \rightarrow C/u^pC \) and \( (C, F(C), \varphi, N) \in \mathcal{L}^* \). The proposition is proved.

The above proof shows that the kernels and cokernels in the category \( \mathcal{L}^* \) appear on the level of filtered modules as the kernel and cokernel of the corresponding map of filtered modules \( (L_1, F(L_1)) \) to \( (L, F(L)) \) in the category of filtered \( \mathcal{W}_1 \)-modules. Therefore, the category \( \mathcal{L}^* \) is special, cf. Appendix A, and we can apply the corresponding formalism of short exact sequences. In particular, if we take another object \( \mathcal{L}_2 = (L_2, F(L_2), \varphi, N) \in \mathcal{L}^* \) then

- \( i \in \text{Hom}_{\mathcal{L}}(L_1, \mathcal{L}) \) is strict monomorphism iff \( i : L_1 \rightarrow L \) is injective and \( i(L_1) \cap F(L) = i(F(L_1)) \);

- \( j \in \text{Hom}_{\mathcal{L}}(\mathcal{L}, \mathcal{L}_2) \) is strict epimorphism iff \( j : L \rightarrow L_2 \) is epimorphic and \( j(F(L)) = F(L_2) \).

As usually, cf. Appendix A, if a monomorphism \( i \) is strict then the monomorphism \( i = \text{Ker} j \) is strict, and if an epimorphism \( j \) is strict then the monomorphism \( i = \text{Ker} j \) is strict, and under these assumptions \( 0 \rightarrow \mathcal{L}_1 \xrightarrow{i} \mathcal{L} \xrightarrow{j} \mathcal{L}_2 \rightarrow 0 \) is short exact sequence.

With relation to the above result that the categories \( \mathcal{L}_0^* \) and \( \mathcal{L}^* \) are pre-abelian, note that the situation with the categories \( \mathcal{L}_0^* \) and \( \mathcal{L}^* \) is different. Indeed, let \( F\mathcal{M}_{\mathcal{W}_1} \) be the category of filtered (not necessarily free) modules over \( \mathcal{W}_1 \). This category is pre-abelian: for \( \mathcal{M}_i = (M_i, F(M_i)), i = 1, 2, \) and \( f \in \text{Hom}_{F\mathcal{M}_{\mathcal{W}_1}}(\mathcal{M}_1, \mathcal{M}_2) \), we have the following equalities Ker\( F\mathcal{M}_{\mathcal{W}_1} f = (\text{Ker} f, \text{Ker} f \cap F(M_1)) \) (together with its natural embedding into \( \mathcal{M}_1 \)) and Coker\( F\mathcal{M}_{\mathcal{W}_1} f = (\text{Coker} f, F(M_2))/(f(M_1) \cap F(M_2)) \) (together with the natural projection from \( \mathcal{M}_2 \)).

Now suppose that \( \mathcal{M}_i = (M_i, F(M_i), \varphi) \in \mathcal{L}_0^*, i = 1, 2, \) and \( f \in \text{Hom}_{\mathcal{L}_0^*}(\mathcal{M}_1, \mathcal{M}_2) \). Then Ker\( F\mathcal{M}_{\mathcal{W}_1} f \) exists (and coincides on the level of filtered modules with Ker\( F\mathcal{M}_{\mathcal{W}_1} f \)) but Coker\( F\mathcal{M}_{\mathcal{W}_1} f \) exists (and coincides on the level of filtered modules with Coker\( F\mathcal{M}_{\mathcal{W}_1} f \)) only if we have \( f(F(M_1)) = f(M_1) \cap F(M_2) \). In particular, on the level of filtered modules the composition Coker\( F\mathcal{M}_{\mathcal{W}_1} (\text{Ker} F\mathcal{M}_{\mathcal{W}_1} f) \) always makes sense and coincides with the natural projection \( \mathcal{M}_1 \rightarrow (f(M_1), f(F(M_1))) \). Therefore, one can introduce the concept of strict epimorphism in \( \mathcal{L}_0^* \): \( f \) is strict epimorphism iff \( f(M_1) = M_2 \) and \( f(F(M_1)) = F(M_2) \).
The following situation will appear several times below.

**Lemma 1.5.** Suppose \( M_1, M_2 \in \mathcal{L}_0^* \), \( \iota \in \text{Hom}_{\mathcal{L}_0^*}(M_1, M_2) \) is a strict epimorphism and \( \text{Ker}_{\mathcal{L}_0^*}\iota = (K, K, \varphi) \). Then for any \( \mathcal{L} \in \mathcal{L}_0^* \),

\[
\iota^* : \text{Hom}_{\mathcal{L}_0^*}(\mathcal{L}, M_1) \to \text{Hom}_{\mathcal{L}_0^*}(\mathcal{L}, M_2)
\]

is epimorphic. In addition, if \( \varphi|_K \) is nilpotent then \( \iota^* \) is bijective.

**Proof.** The structure of \( \mathcal{L} = (L, F(L), \varphi) \) can be given by a vector \( \bar{l} = (l_1, \ldots, l_s) \) and a matrix \( C \in M_s(W_1) \) such that

- \( l_1, \ldots, l_s \) is a \( W_1 \)-basis of \( L \);
- if \( lC = \bar{m} = (m_1, \ldots, m_s) \) then \( m_1, \ldots, m_s \) is a \( W_1 \)-basis of \( F(L) \);
- \( \bar{m} = \varphi(\bar{m}) := (\varphi(m_1), \ldots, \varphi(m_s)) \).

Suppose \( M_1 = (M_1, F(M_1), \varphi) \) and \( M_2 = (M_2, F(M_2), \varphi) \). Any \( f \in \text{Hom}_{\mathcal{L}_0^*}(\mathcal{L}, M_2) \) is given by \( f(\bar{l}) \in M_2^* \) such that \( f(\bar{l})C \in F(M_2)^* \) and \( \varphi(f(\bar{l})C) = f(\bar{l}) \).

Choose an \( \tilde{f}(\bar{l}) \in M_2^* \) such that \( \tilde{f}(\bar{l}) \mod K = f(\bar{l}) \). Then \( \tilde{f}(\bar{l})C \mod K \) belongs to \( F(M_2)^* \) and, therefore, \( \tilde{f}(\bar{l})C \in F(M_2)^* \). Clearly, we have that \( \tilde{k}_0 := \varphi(\tilde{f}(\bar{l})C) - f(\bar{l}) \in K^* \). We must prove the existence of \( \tilde{k}_1 \in K^* \) such that \( \varphi((\tilde{f}(\bar{l}) + \tilde{k}_1)C) = \tilde{f}(\bar{l}) + \tilde{k}_1 \). This is equivalent to

\[
\tilde{k}_1 - \varphi(\tilde{k}_1C) = \tilde{k}_0
\]

and the existence of \( \tilde{k}_1 \) follows from Lemma 1.1. This proves that \( \iota^* \) is surjective. If \( \varphi|_K \) is nilpotent then the bijectivity of \( \iota^* \) follows in a similar way from part b) of Lemma 1.1. \( \square \)

1.2. **Standard exact sequences.** Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}_0^* \). Introduce a \( \sigma \)-linear map \( \phi : L \to L \) by \( \phi : l \mapsto \varphi(u^{p-1}l) \).

**Definition.** The object \( \mathcal{L} \) is etale (resp., connected) if \( \phi \mod u \) is invertible (resp., nilpotent) on \( L/uL \).

Let \( \mathcal{L}(0) = (W_1, W_1 u^{p-1}, \varphi, N) \in \mathcal{L}_0^* \), where \( \varphi(u^{p-1}) = 1 \) and \( N(1) = u^p \mod u^{2p} \). Then \( \mathcal{L}(0) \) is etale. As a matter of fact, it is the simplest etale object of \( \mathcal{L}_0^* \) due to the following Lemma.

**Lemma 1.6.** Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}_0^* \) is etale. Then \( \mathcal{L} \) is a product of finitely many copies of \( \mathcal{L}(0) \).

**Proof.** If \( \tilde{L}_0 = \{l \in L/uL \mid \phi(l) = l\} \) then \( L/uL = \tilde{L}_0 \otimes_{\mathbb{F}_p} k \). Then there is a unique \( \mathbb{F}_p \)-submodule \( L_0 \) of \( L \) such that \( \phi|_{L_0} = \text{id} \) and \( L = L_0 \otimes_{\mathbb{F}_p} W_1 \).

Suppose \( l \in L_0 \). Then \( \varphi(u^{p-1}l) = l \) and \( N(l) = N(\varphi(u^{p-1}l)) = \varphi(uN(u^{p-1}l)) = \varphi(u^p(l \mod u^{2p}) + u^pN(l)) = u^p l \mod u^{2p} L \). Therefore, if \( e_1, \ldots, e_s \) is an \( \mathbb{F}_p \)-basis of \( L_0 \) then all \( (W_1 e_i, W_1 u^{p-1} e_i) \) determine the subobjects \( \mathcal{L}_i \simeq \mathcal{L}(0) \) of \( \mathcal{L} \) and \( \mathcal{L} \simeq \mathcal{L}_1 \times \cdots \times \mathcal{L}_s \). \( \square \)
Proposition 1.7. Any \( \mathcal{L} \in \mathcal{L}^* \) contains a unique maximal etale subobject \( (\mathcal{L}^{et}, l^{et}) \) and a unique maximal connected quotient object \( (\mathcal{L}^c, f^c) \) and the sequence \( 0 \to \mathcal{L}^{et} \xrightarrow{l^{et}} \mathcal{L} \xrightarrow{f^c} \mathcal{L}^c \to 0 \) is short exact.

Proof. Let \( \mathcal{L} = (L, F(L), \varphi, N) \) and, as earlier, let \( \phi : L \to L \) be such that for any \( l \in L \), \( \phi(l) = \varphi(u^{p^{-1}}l) \). Then for \( \hat{L} = L/uL \), we have the \( k \)-linear subspaces \( \hat{L}^{et} \) and \( \hat{L}^c \) in \( \hat{L} \) such that \( \hat{\phi} := \phi \mod u \) is invertible on \( \hat{L}^{et} \) and nilpotent on \( \hat{L}^c \) and \( \hat{L} = \hat{L}^{et} \oplus \hat{L}^c \).

Then there is a unique \( W_0 \)-submodule \( L^{et} \) of \( L \) such that \( \phi|_{L^{et}} \) is invertible and \( L^{et}/uL^{et} = \hat{L}^{et} \). The filtered submodule \( (L^{et}, u^{p^{-1}}L^{et}) \) determines an etale subobject \( l^{et} : \mathcal{L}^{et} \to \mathcal{L} \). Clearly, \( u^{p^{-1}}L^{et} \subset L^{et} \cap F(L) \). If the inverse embedding does not take place then there is an \( l \in L^{et}\setminus uL^{et} \) such that \( u^{p^{-1}}l \in uF(L) \). Therefore, \( \phi(l) = \varphi(u^{p^{-1}}l) \notin uL \) but \( \phi|_{L^{et}} \) is invertible. So, \( l^{et} \) is strict monomorphism and we can consider \( \text{Coker} l^{et} = f^{c} : \mathcal{L} \to \mathcal{L}^{c} \). Clearly, \( \mathcal{L}^{c} \) is connected. The maximality properties of \( L^{et} \) and \( \mathcal{L}^{c} \) are formally implied by the following easy statement:

if \( L_1 \in \mathcal{L}^* \) is etale and \( L_2 \in \mathcal{L}^* \) is connected then \( \text{Hom}_{\mathcal{L}}(L_1, L_2) = 0 \). \( \square \)

Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^* \). Then \( \varphi(F(L)) \) is a \( \sigma(W_1) \)-module and \( L = \varphi(F(L)) \otimes \sigma(W_1) W_1 \). If \( l \in L \) and for \( 0 \leq i < p \), \( l^{(i)} \in F(L) \) are such that \( l = \sum_{0 \leq i < p} \varphi(l^{(i)}) \otimes u^i \), set \( V(l) = l^{(0)} \). Then \( V \mod u \) is a \( \sigma^{-1} \)-linear endomorphism of the \( k \)-vector space \( L/uL \).

Definition. The module \( \mathcal{L} \) is multiplicative (resp., unipotent) if \( \hat{V} := V \mod u \) is invertible (resp., nilpotent) on \( \hat{L} := L/uL \).

Let \( \mathcal{L}(1) = (W_1, W_1, \varphi, N) \in \mathcal{L}^* \), where \( \varphi(1) = 1 \) and \( N(1) = 0 \). Then \( \mathcal{L}(1) \) is multiplicative. As a matter of fact, it is the simplest multiplicative object of \( \mathcal{L}^* \) due to the following Lemma.

Lemma 1.8. Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^* \) is multiplicative, then \( \mathcal{L} \) is the product of finitely many copies of \( \mathcal{L}(1) \).

Proof. Clearly, the embedding \( F(L) \to L \) induces the identification \( F(L)/uF(L) = L/uL \) and, therefore, \( F(L) = L \).

Let \( \hat{L}_0 \subset \hat{L} \) be such that \( \hat{V}|_{\hat{L}_0} = \text{id} \). If \( l \in L \) is such that \( l \mod uL \in \hat{L}_0 \) then \( \varphi(l) \equiv l \mod uL \). This implies the existence of a unique \( l' \in L \) such that \( l' \equiv l \mod uL \) and \( \varphi(l') = l' \). In other words, there is an \( \mathbb{F}_p \)-submodule \( L_0 \) in \( L \) such that \( L = L_0 \otimes_{\mathbb{F}_p} W_1 \) and \( \varphi|_{L_0} = \text{id} \).

If \( l \in L_0 \) then \( N(l) = N(\varphi(l)) = \varphi(uN(l)) = u^p\varphi(N(l)) = 0 \). So, if \( e_1, \ldots, e_s \) is an \( \mathbb{F}_p \)-basis of \( L_0 \) then the filtered modules \( (W_1 e_i, W_1 e_i) \) determine the subobjects \( \mathcal{L}_i \simeq \mathcal{L}(1) \) of \( \mathcal{L} \) and \( \mathcal{L} \simeq \mathcal{L}_1 \times \cdots \times \mathcal{L}_s \). \( \square \)

Proposition 1.9. Any \( \mathcal{L} = (L, M, \varphi, N) \in \mathcal{L}^* \) contains a unique maximal multiplicative quotient object \( (\mathcal{L}_m, j^m) \) and a unique maximal unipotent subobject.
\((L^u, i^u)\) and the sequence

\[
0 \rightarrow L^u \xrightarrow{i^u} L \xrightarrow{j^m} L^m \rightarrow 0
\]
is exact.

Proof. Let \(\tilde{L} = L/uL, \tilde{M} = M/uM\) and \(\tilde{L} = \tilde{L}^m \oplus \tilde{L}^u\), where \(\tilde{V} := V \mod u\) is invertible on \(\tilde{L}^m\) and nilpotent on \(\tilde{L}^u\).

Note that \(\varphi\) induces a \(\sigma\)-linear isomorphism \(\tilde{\varphi} : \tilde{M} \rightarrow \tilde{L}\). Denote by \(\tilde{i} : \tilde{M} \rightarrow \tilde{L}\) the \(k\)-linear morphism induced by the embedding \(M \rightarrow L\). With this notation, for any \(l \in \tilde{L}\), \(\tilde{V}(l) = \tilde{i}(\tilde{\varphi}^{-1}(l))\).

Consider the filtration \(\tilde{L}^u \supset V\tilde{L}^u \supset \cdots \supset \tilde{V}\tilde{L}^u = \{0\}\) and set for \(1 \leq i \leq s + 1\), \(\tilde{M}_i = \tilde{\varphi}^{-1}(\tilde{V}^{i-1}\tilde{L}^u)\). Then \(\tilde{M}_1 \supset \tilde{M}_2 \supset \cdots \supset \tilde{M}_s \supset \tilde{M}_{s+1} = \{0\}\) and for \(1 \leq i \leq s\),

\[
(1.1) \quad \tilde{i}(\tilde{M}_i) = \tilde{V}^i\tilde{L}^u = \tilde{\varphi}(\tilde{M}_{i+1}).
\]

For \(1 \leq i \leq s + 1\), introduce the \(W_i\)-submodules \(M_i^{(0)}\) of \(M\) such that \(M_i^{(0)} \supset M_2^{(0)} \supset \cdots \supset M_s^{(0)} \supset M_{s+1}^{(0)} = 0\) and \(M_i^{(0)}/uM_i^{(0)} = \tilde{M}_i\) with respect to the natural projection \(M \rightarrow \tilde{M}\). Then conditions \((1.1)\) imply that for all \(i\),

\[
M_i^{(0)} \subset \varphi(M_{i+1}^{(0)}) \circ \sigma W_i W_1 + uL.
\]

Let \(\tilde{M}_m = \tilde{\varphi}^{-1}(\tilde{L}^m)\) and let \(M_m \subset M\) be a \(W_i\)-submodule such that \(M_m/uM_m = \tilde{M}_m\) with respect to the natural projection \(M \rightarrow \tilde{M}\). Then

\[
(1.2) \quad M_m + uL = \varphi(M_m) \circ \sigma W_i W_1 + uL
\]

and \(M = M_m \oplus M_i^{(0)}\).

Prove the existence of “more precise” lifts \(M_i^{(n)}\) of \(\tilde{M}_i\), where \(0 \leq i \leq s + 1\) and \(n \geq 1\).

Lemma 1.10. For all \(n \geq 1\) and \(0 \leq i \leq s + 1\), there are \(W_i\)-modules \(M_i^{(n)}\) such that

a) \(M_1^{(n)} \supset M_2^{(n)} \supset \cdots \supset M_s^{(n)} \supset M_{s+1}^{(n)} = \{0\}\) and \(M_i^{(n)}/uM_i^{(n)} = \tilde{M}_i\) with respect to the natural projection \(M \rightarrow \tilde{M}\);

b) \(M_i^{(n)} \subset \varphi(M_{i+1}^{(n)}) \circ \sigma W_i W_1 + u\varphi(M_{i+1}^{(n)}) \circ \sigma W_i W_1 + u^{n+1}L\);

c) \(M_i^{(n-1)} + u^n M = M_i^{(n)} + u^n M\).

Proof of Lemma. The modules \(M_i^{(0)}, 0 \leq i \leq s + 1\), satisfy the requirements a) and b) of our Lemma. Therefore, we can assume that the modules \(M_i^{(n)}\) satisfying the requirements a)-c) have been already constructed for \(n = N - 1\), where \(N \geq 1\).

Note that \(M = M_m \oplus M_i^{(N-1)}\) (it is known for \(N = 1\) and follows from c) for \(N > 1\)). Therefore, \((1.2)\) implies that

\[
L = \varphi(M_m) \circ \sigma W_i W_1 + \varphi(M_i^{(N-1)}) \circ \sigma W_i W_1
\]

\[
\subset M_m + \varphi(M_i^{(N-1)}) \circ \sigma W_i W_1 + uL.
\]
Therefore, for $1 \leq i \leq s$ (use b) for $n = N - 1$,
\[ M_{i}^{(N-1)} \subset \varphi(M_{i+1}^{(N-1)}) \otimes_{\sigma W_i} W_i + u \varphi(M_{i}^{(N-1)}) \otimes_{\sigma W_i} W_i + u^{N} M^m + u^{N+1} L \]
and we can define the submodules $M_i^{(N)}$ in such a way that the property c) holds for $n = N$
\[ M_i^{(N)} + u^{N} M^m = M_i^{(N-1)} + u^{N} M^m \]
and
\[ M_i^{(N)} \subset \varphi(M_{i+1}^{(N-1)}) \otimes_{\sigma W_i} W_i + u \varphi(M_{i}^{(N-1)}) \otimes_{\sigma W_i} W_i + u^{N+1} L. \]
Note that (1.3) implies that $\varphi(M_i^{(N)}) + u^{Np} L = \varphi(M_{i}^{(N-1)}) + u^{Np} L$ and, therefore, we can replace $\varphi(M_i^{(N-1)})$ and $\varphi(M_{i}^{(N-1)})$ by $\varphi(M_i^{(N)})$ and, resp. $\varphi(M_i^{(N)})$ in (1.4). The lemma is proved.

Let $M^u = \bigcap_{n > 0}(M^{1(n)} + u^{n+1} M)$. Then $M^u/uM^u = \tilde{M}^u$ with respect to the natural projection $M \twoheadrightarrow M$ and $M = M^m \oplus M^u$.
Let $L^u = \varphi(M^u) \otimes_{\sigma W_i} W_i$. Then $\text{rk}_{W_i} L^u = \text{rk}_{W_i} M^u$ and
\[ L^u = \bigcap_{n > 0} \left( \varphi(M_{i}^{(n)}) \otimes_{\sigma W_i} W_i + u^{(n+1)p} L \right) \supset M^u \]
(\text{use Lemma 1.10b}). On the other hand,
\[ L = \varphi(M^m \oplus M^u) \otimes_{\sigma W_i} W_i = M^m \oplus L^u \]
implies that $M^u \supset u^{p-1} L^u$ and $L^u \cap M = M^u$. Therefore, the filtered module $(L^u, M^u)$ defines a unipotent subobject $L^u$ of $L$ in the category $L^*$ and the natural embedding $L^u \rightarrow L$ is strict.
Suppose $l \in M^u$ and $N(l) \equiv l_0 + l_1 \mod u^p L$, where $l_0 \in M^m$ and $l_1 \in L^u$. Then $uN(l) \equiv ul_0 + ul_1 \in (M^m \oplus M^u) \mod u^p L$ and $N(\varphi(l)) \equiv \varphi(ul_1) \mod u^p L$ implies that $N(L^u) \subset L^u \mod u^p L$. Then from Proposition 1.2 it follows that $L^u$ is a subobject of $L$ in the category $L^*$. Clearly, the quotient $L/L^u := \tilde{L}^m$ is multiplicative.
The maximality of $L^u$ and $L^m$ are formally implied by the following easy property of objects $L_1, L_2 \in L^*$:
if $L_1$ is unipotent and $L_2$ is multiplicative then $\text{Hom}_{L^*}(L_1, L_2) = 0$.

Using the above results we can introduce the subcategories $L^{*, u}, L^{*, c}, L^{*, m}, L^{*, et}$ in $L^*$. They consist of, resp., etale, connected, multiplicative and unipotent objects of the category $L^*$. The correspondences $L \rightarrow L^{*, u}, L \rightarrow L^{*, c}, L \rightarrow L^{*, m}, L \rightarrow L^{*, et}$ determine the natural exact functors from $L^*$ to, resp., $L^{*, u}, L^{*, c}, L^{*, m}$ and $L^{*, et}$.
1.3. The category \( \mathcal{L}^*_r \).

**Proposition 1.11.** Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^*_r \). Then the following conditions are equivalent:

(a) \( N(F(L)) \subset F(L) \mod u^{2p}L \);

(b) \( N(\varphi(F(L))) \subset u^pL \mod u^{2p}L \).

**Proof.** (a) \( \Rightarrow \) (b): if for any \( l \in F(L) \), \( N(l) \in F(L) \mod u^{2p}L \) then \( N(\varphi(l)) = \varphi(uN(l)) = u^p\varphi(N(l)) \in u^pL \mod u^{2p}L \).

(b) \( \Rightarrow \) (a): for any \( l \in F(L) \), \( \varphi(uN(l)) = N(\varphi(l)) \in u^pL \mod u^{2p}L \); now use that \( \varphi \) induces embedding of \( F(L)/uF(L) \) into \( L/u^pL \) to deduce that \( N(l) \in uF(L) \mod u^{2p}L \), i.e. \( N(l) \in F(L) \mod u^{2p}L \) (use that \( u^{p-1}L \subset F(L) \)). □

**Definition.** The category \( \mathcal{L}^*_r \), is a full subcategory of \( \mathcal{L}^* \) consisting of \( (L, F(L), \varphi, N) \) such that \( N : L \to L \) satisfies the equivalent conditions from Proposition 1.11.

**Remark.** a) If \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^*_r \), then \( N_1 = N \mod u^p \) is a unique \( W_1 \)-differentiation \( N_1 : L \to L/u^pL \) whose restriction to \( \varphi(F(L)) \) is the zero map. Therefore, any \( \mathcal{L} \in \mathcal{L}^*_0 \) has at most one structure of object of the category \( \mathcal{L}^*_r \).

b) Any etale or multiplicative object from \( \mathcal{L}^*_r \) belongs to \( \mathcal{L}^*_r \).

c) If \( f \) is a morphism in \( \mathcal{L}^*_r \), then \( \ker \mathcal{L}^*_r f = \ker \mathcal{L}^*_r f \) and \( \coker \mathcal{L}^*_r f = \coker \mathcal{L}^*_r f \). In particular, we can introduce the full subcategories \( \mathcal{L}^*_e \), \( \mathcal{L}^*_c \), \( \mathcal{L}^*_m \), \( \mathcal{L}^*_u \) of, resp., etale, connected, multiplicative and unipotent objects of \( \mathcal{L}^*_r \).

**Proposition 1.12.** Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^*_r \). Then there is a \( \sigma(W_1) \)-basis \( l_1, \ldots, l_s \) of \( \varphi(F(L)) \) and integers \( 0 \leq c_i < p \), where \( 1 \leq i \leq s \), such that \( u^{c_i}l_1, \ldots, u^{c_s}l_s \) is a \( W_1 \)-basis of \( F(L) \).

**Proof.** Choose a \( W_1 \)-basis \( m_1, \ldots, m_s \) of \( L \) such that for suitable integers \( c_1, \ldots, c_s \), the elements \( u^{c_1}m_1, \ldots, u^{c_s}m_s \) form a \( W_1 \)-basis of \( F(L) \). Clearly all \( 0 \leq c_i < p \).

For \( 1 \leq i \leq s \) and \( j \geq 0 \), let \( l_{ij} \in \varphi(F(L)) \) be such that \( m_i = \sum_{j \geq 0} w^j l_{ij} \). Note that \( \{ l_{ij} \mid 1 \leq i \leq s \} \) is a \( \sigma(W_1) \)-basis of \( \varphi(F(L)) \) and it will be sufficient to prove that all \( u^{c_i}l_i \in F(L) \) because then the elements \( l_i := l_{0i} \) will satisfy the requirements of our proposition.

For all \( 1 \leq i \leq s \), the element

\[
N(u^{c_i}m_i) = -\sum_j (j + c_i)u^{j+c_i}(l_{ij}) \mod u^{2p}L \quad + \quad \sum_j u^{j+c_i}N(l_{ij})
\]

belongs to \( F(L) \mod u^{2p}L \) if and only if \( \sum_j (j + c_i)u^{j+c_i}l_{ij} \in F(L) \). (Use that \( u^{p}L \subset uF(L) \).) This implies that for all integers \( k \geq 0 \), \( \sum_j (j + c_i)^k u^{j+c_i}l_{ij} \in F(L) \). Therefore, for any \( \alpha \in \mathbb{Z}/p\mathbb{Z} \),

\[
\sum_{(j+c_i) \mod p = \alpha} u^{j+c_i}l_{ij} \in F(L).
\]
In particular, taking $a = c_i \mod p$ and using that $u^pl_{ij} \in F(L)$, we obtain that $u^c_l \in F(L)$. \hfill \Box

**Remark.** a) Suppose $\mathcal{L} = (L, F(L), \varphi) \in \mathcal{L}^*_p$ and satisfies the conclusion of Proposition 1.12. Define the $W_1$-differentiation $N_1 : L \to L/u^pL$ by setting $N_1(l_1) = \cdots = N(l_p) = 0$. If $N : L \to L/u^2pL$ is the extension of $N_1$ given by Proposition 1.2 then $(L, F(L), \varphi, N) \in \mathcal{L}^*_p$. In other words, Proposition 1.12 characterizes the objects of $\mathcal{L}^*_p$ coming from $\mathcal{L}^*_p$.

b) For an object $(L, F(L), \varphi, N) \in \mathcal{L}^*_p$, Proposition 1.12 implies that if $\sum_{0 \leq i < p} u^i l_i \in F(L)$, where all $l_i \in \varphi(F(L))$, then all $u^i l_i \in F(L)$.

Consider the category of filtered Fontaine-Laffaille modules $\text{MF}_{p^{-1}}$ from [13]. The objects of this category are finite dimensional $k$-vector spaces $M$ with decreasing filtration of length $p$ by subspaces $M = M^0 \supset M^1 \supset \cdots \supset M^{p-1} \supset M^p = 0$ and $\sigma$-linear maps $\varphi_i : M^i \to M$ such that $\text{Ker} \varphi_i \supset M^{i+1}$, where $0 \leq i < p$, and $\sum_i \text{Im} \varphi_i = M$. The morphisms in $\text{MF}_{p^{-1}}$ are the morphisms of filtered vector spaces which commute with the corresponding morphisms $\varphi_i$, $0 \leq i < p$.

The category $\text{MF}_{p^{-1}}$ is abelian. The object $M$ of $\text{MF}_{p^{-1}}$ is:

- étale (resp., multiplicative) if $M^1 = 0$ (resp., $M = M^{p-1}$);
- connected (resp., unipotent) if $M$ has no étale (resp., multiplicative) sub-quotient.

Introduce the full subcategories $\text{MF}^*_p$, $\text{MF}^m_p$, $\text{MF}^c_p$ and $\text{MF}^u_p$ of, resp., étale, multiplicative, connected and unipotent objects in $\text{MF}_{p^{-1}}$. These subcategories are closed under the operations of taking subobjects and quotient objects and, therefore, are also abelian. For any $M \in \text{MF}_{p^{-1}}$, there are standard exact sequences $0 \to M^e \to M \to M^c \to 0$ and $0 \to M^u \to M \to M^m \to 0$, where $M^e$ (resp., $M^u$) is the maximal étale (resp., unipotent) subobject and $M^c$ (resp., $M^m$) is the maximal connected (resp., multiplicative) quotient object.

The categories $\mathcal{L}^*_p$ and $\text{MF}_{p^{-1}}$ do not differ very much.

Indeed, introduce the functor $\text{Md} : \mathcal{L}^*_p \to \mathcal{L}^*_p$ induced on the level of filtered modules by $(L, F(L)) \mapsto (L/u^pL, F(L)/u^pL)$. Denote by $\text{Md}(\mathcal{L}^*_p)$ the full subcategory of $\mathcal{L}^*_p$ consisting of the objects $\text{Md}(L)$, where $L \in \mathcal{L}^*_p$.

Define the functor $\mathcal{F} : \text{MF}_{p^{-1}} \to \mathcal{L}^*_p$ as follows. Let $M \in \text{MF}_{p^{-1}}$ with the corresponding filtration $M^i$ and $\sigma$-linear morphisms $\varphi_i$, $0 \leq i < p$. Then on the level of objects, $\mathcal{F}(M) = (L, F(L), \varphi, N)$, where $L = M \otimes_k W_1/u^pW_1$, $F(L) = \sum_{0 \leq i < p} u^{p-1-i}W_1(M^i \otimes 1)$ and for any $m \in M_i$, $\varphi(u^{p-1-i}m) = \varphi_i(m)$. One can easily see that $\mathcal{F}$ is equivalence of the categories $\text{MF}_{p^{-1}}$ and $\text{Md}(\mathcal{L}^*_p)$.

Now the difference between the categories $\mathcal{L}^*_p$ and $\text{MF}_{p^{-1}}$ is described by the following Proposition.

**Proposition 1.13.** For $\mathcal{L}_1, \mathcal{L}_2 \in \mathcal{L}^*_p$, $\text{Md}$ induces a surjection from $\text{Hom}_{\mathcal{L}^*_p}(\mathcal{L}_1, \mathcal{L}_2)$ to $\text{Hom}_{\mathcal{L}^*_p}(\text{Md}(\mathcal{L}_1), \text{Md}(\mathcal{L}_2))$ and its kernel coincides with
(i_{L_2^*} \circ j_{L_2^*}) \text{Hom}_{L^*}(L_1^m, L_2^*)$, where $i_{L_2^*} : L_2^* \rightarrow L_2$ (resp., $j_{L_1^*} : L_1 \rightarrow L_1^m$) is the maximal etale subobject in $L_2$ (resp., multiplicative quotient object for $L_1$).

**Proof.** For $L_2 = (L_2, F(L_2), \varphi, N)$, let $\phi : L_2 \rightarrow L_2$ be such that $\phi(l) = \varphi(u^p - 1)l$ for any $l \in L_2$. Let $L_2^c = \{l \in L_2 \mid \phi(l)^n \rightarrow 0\}$ and let $L_2' \in \text{L}^*$ be the filtered module $(L_2/u^nL_2', F(L_2)/u^nL_2')$ with $\varphi$ and $N$ induced from $L_2$. Then there are natural strict epimorphisms

$$L_2 \rightarrow \alpha \rightarrow L_2' \rightarrow \text{Md}(L_2),$$

where Ker $\alpha$ is associated with the filtered module $(u^pL_2', u^pL_2''')$ and Ker $\beta$ — with $(u^pL_2'/u^pL_2', u^pL_2'/u^pL_2'')$. Clearly, $\varphi|_{u^pL_2'}$ is nilpotent and then by Lemma 1.5,

$$\alpha_* : \text{Hom}_{\text{L}^*}(L_1, L_2) \rightarrow \text{Hom}_{\text{L}^*}(L_1, L_2')$$

is bijective. Note that the natural embedding $L_2^c \rightarrow L_2$ induces the identification $u^pL_2'/u^pL_2''' = u^p L_2''' / u^p L_2'$. Let $L_2''' = (u^pL_2', u^pL_2'') \in \text{L}^\cdot$ with inducing $\varphi$ and $N$. Then $L_2'''$ is multiplicative and there is a natural projection $\gamma : L_2''' \rightarrow \text{Ker} \beta$ such that Ker $\gamma$ is associated with $(u^p+1L_2''', u^p+1L_2''')$. Note that $\varphi$ is nilpotent on $u^{p+1}L_2'''$. Applying Lemma 1.5 we obtain that

$$\beta_* : \text{Hom}_{\text{L}^*}(L_1, L_2') \rightarrow \text{Hom}_{\text{L}^*}(L_1, \text{Md}(L_2))$$

is surjective and

$$\text{Ker} \beta = \text{Hom}_{\text{L}^*}(L_1, \text{Ker} \beta) = \text{Hom}_{\text{L}^*}(L_1, L_2') \simeq \text{Hom}(L_1^m, L_2''').$$

It remains to note that $\text{Hom}_{\text{L}^*}(L_1^m, L_2''') = \text{Hom}_{\text{L}^*}(L_1^m, L_2''')$ via the natural embedding of $L''$ into $L_2^c$.

**Corollary 1.14.** The functor $\text{Md} \circ F^{-1}$ induces equivalence of the categories $\text{L}^c_r$ (resp., $\text{L}^c_{\text{cr}}$) and $\text{MF}^c_{p-1}$ (resp., $\text{MF}^c_{p-1}$).

**1.4. Simple objects in $\text{L}^*$.**

**Definition.** An object $L$ of $\text{L}^*$ is simple if any strict monomorphism $i : L_1 \rightarrow L$ in $\text{L}^*$ is either isomorphism or the zero morphism. Equivalently, $L$ is simple iff any strict epimorphism $j : L \rightarrow L_2$ is either isomorphism or the zero morphism.

All simple objects in $\text{L}^*$ can be described as follows.

Let $\{0, 1\}_p = \{r \in \mathbb{Q} \mid 0 \leq r \leq 1, v_\rho(r) = 0\}$, where $v_\rho$ is a $p$-adic valuation. Then any $r \in [0, 1]_p$ can be uniquely written as $r = \sum_{i \geq 1} a_ip^{-i}$, where the digits $0 \leq a_i = a_i(r) < p$ form a periodic sequence. The minimal positive period of this sequence will be denoted by $s(r)$.

Let $\tilde{r} = 1 - r$. Then $\tilde{r} \in [0, 1]_p$ and $\tilde{r} = \sum_{i \geq 1} \tilde{a}_ip^{-i}$, where for all $i \geq 1$, the digits $\tilde{a}_i = a_i(\tilde{r})$ are such that $a_i + \tilde{a}_i = p - 1$. The document is about varieties with bad reduction at 3, and the proof involves the study of objects in $\text{L}^*$ and their properties, including strict monomorphisms and epimorphisms, as well as the concept of simple objects. The proof includes a specific construction involving filtrations and filtered modules to establish equivalences between categories.
DEFINITION. For \( r \in [0,1)_p \), let \( \mathcal{L}(r) = (L(r), F(L(r)), \varphi, N) \) be the following object of the category \( \mathcal{L}^r \):
- \( L(r) = \oplus_{i \in \mathbb{Z}/s(r)} W_i l_i \);
- \( F(L(r)) = \sum_{i \in \mathbb{Z}/s(r)} W_i u^i l_i \);
- for \( i \in \mathbb{Z}/s(r) \), \( \varphi(u^i l_i) = l_{i+1} \).
- \( N \) is uniquely recovered from the condition \( N|_{\varphi(F(L))} = 0 \) mod \( u^p \), cf. Proposition 1.2.

REMARK. If \( r = 0 \) or \( r = 1 \) we obtain the objects \( \mathcal{L}(0) \) and \( \mathcal{L}(1) \) introduced in Subsection 1.2. Note also that \( \mathcal{L}(r) \) is connected iff \( r \neq 0 \) and unipotent iff \( r \neq 1 \).

For \( n \in \mathbb{N} \) and \( r \in [0,1)_p \), set \( r(n) = \sum_{i \geq 1} a_{i+n(r)} p^{-i} \). Extend this definition to any \( n \in \mathbb{Z} \) by setting \( r(n) := r(n + Ns(r)) \) for a sufficiently large \( N \in \mathbb{N} \).

**Proposition 1.15.**
(a) If \( r \in [0,1)_p \) then \( \mathcal{L}(r) \) is simple;
(b) if \( r_1, r_2 \in [0,1)_p \) then \( \mathcal{L}(r_1) \simeq \mathcal{L}(r_2) \) if and only if there is an \( n \in \mathbb{Z} \) such that \( r_1 = r_2(n) \);
(c) if \( \mathcal{L} \) is a simple object of the category \( \mathcal{L}^r \) then there is an \( r \in [0,1)_p \) such that \( \mathcal{L} \simeq \mathcal{L}(r) \).

**Proof.** Lemma 1.16 below implies that the simple objects in the categories \( \mathcal{L}^r \) and \( \mathcal{L}^r \) are the same. By Corollary 1.14, the functor \( \text{Md} \circ F^{-1} \) transforms simple objects of \( \mathcal{L}^r \) to simple objects in \( \mathcal{MF}_{p-1} \). It remains to note that an analogue of our Proposition for the category \( \mathcal{MF}_{p-1} \) is proved in [13].

**Lemma 1.16.** For any \( \mathcal{L} \in \mathcal{L}^r \), there is an \( \mathcal{L}' \in \mathcal{L}^r \) and a strict monomorphism \( \iota' : \mathcal{L} \hookrightarrow \mathcal{L}' \) such that \( \varphi' \in \text{Hom}_{\mathcal{L}^r}(\mathcal{L}', \mathcal{L}) \) is a strict monomorphism and \( \mathcal{L}' \in \mathcal{L}^r \) if there is a strict monomorphism \( \alpha : \mathcal{L}' \hookrightarrow \mathcal{L}^r \) such that \( \iota'' = \iota' \circ \alpha \).

**Proof of Lemma.** Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \). Consider the \( k \)-linear space \( M := \varphi(F(L))/u^p \varphi(F(L)) \). Let \( \tilde{L} = M \otimes_k (W_i/u^i W_i) = L/u^p L, \tilde{F} = F(L)/u^p L \) and \( \tilde{\varphi} : \tilde{F} \to M \) be the map induced by \( \varphi \).

Proceed by induction to define for all \( i \geq 1 \), the subspaces \( M_i \subseteq M \) and the \( W_i \)-submodules \( \tilde{F}_i \subseteq \tilde{L} \) as follows.

From the definition of \( N : L \to L/u^p L \) it follows easily that \( N \) induces a \( k \)-linear map \( \tilde{N}_1 : M \to M \) and \( \tilde{N}_1^p = 0 \). Therefore, \( M_1 := \text{Ker} \tilde{N}_1 \) is a non-trivial subspace in \( M \).

Suppose \( i \geq 1 \) and \( M_i \) has been already defined. Let \( \tilde{F}_i \) be the submodule of the elements of the form \( u^i l \) in \( M \otimes_k (W_i/u^i W_i) \), where \( a \geq 0, l \in M_i \) and \( u^i l \in \tilde{F}_i \). Then set \( M_{i+1} = \tilde{\varphi}(\tilde{F}_i) \).

Verify that for all indices \( i \), \( M_{i+1} \subseteq M_i \). If \( i = 1 \) we must prove that \( \tilde{N}_1(M_2) = 0 \). Indeed, \( M_2 \) is spanned by \( \varphi(u^l) \), where \( l \in M_1 \) and \( u^l \in \tilde{F}_1 \). But \( N(\varphi(u^l)) = \varphi(uN(u^l)) = \varphi(-u^{l+1} + u^{l+1} N(l)) \in u^p L \). If \( i > 1 \) then we can assume by induction that \( M_{i-1} \subseteq M_i \). This implies that \( \tilde{F}_{i-1} \subseteq \tilde{F}_i \) and \( M_i \subseteq M_{i+1} \).
We obtained a decreasing sequence of non-trivial finite dimensional $k$-linear spaces $\{M_i \mid i \geq 1\}$. For $i \gg 1$, these spaces become a non-trivial constant space $M^{cr} \subset M$ such that if $F^{cr} = \{u^l \in F \mid a \geq 0, l \in M^{cr}\}$ then $\tilde{\varphi}(F^{cr}) = M^{cr}$.

This subspace $M^{cr}$ has the maximality property: if $M' \subset M$ is such that for $F' = \{u^l \in F \mid a \geq 0, l \in M'\}$, $\tilde{\varphi}(F') = M'$ then $M' \subset M^{cr}$. Indeed, show as earlier that $M' \subset M_1$ and then proceed by induction proving that $M' \subset M_i$ for all $i \geq 1$.

Now in notation from Subsection 1.3, there is an $L^{cr} \in L^{cr}_r$ such that $\text{Md}(L^{cr}) = (M^{cr} \otimes_k (\mathcal{W}_1/u\mathcal{W}_1), \tilde{F}^{cr}, \tilde{\varphi}, \tilde{N})$, where $\tilde{N}|_{M^{cr}} = 0$. Then from Proposition 1.13 it follows the existence of a strict monomorphism $s^{cr} : L^{cr} \hookrightarrow L$. If $L' = (L, F(L'), \varphi, N) \rightarrow L$ is strict monomorphism and $L' \in L^{cr}_r$ then $L_1 = \text{Md}(L')$ is associated with the filtered module $(M' \otimes_k (\mathcal{W}_1/u\mathcal{W}_1), \tilde{F}')$ and by the above maximality property of $M^{cr}$, $M'$ is a subspace in $M^{cr}$ and $\text{Md}(L')$ is a strict subobject of $\text{Md}(L^{cr})$. This gives the required strict embedding $\alpha$.

The Lemma follows.

1.5. Extensions in $L^{cr}_r$. Suppose $r_1, r_2 \in [0, 1]_s$. Choose an $s \in \mathbb{N}$ which is divisible by $s(r_1)$ and $s(r_2)$ and introduce the objects $L_1 = (L_1, F(L_1), \varphi, N)$ and $L_2 = (L_2, F(L_2), \varphi, N)$ of the category $L^{cr}_r$ as follows:

$L_1 = \oplus_{i \in \mathbb{Z}/s} \mathcal{W}_i \gamma^{1, 0}, F(L_1) = \sum_{i \in \mathbb{Z}/s} \mathcal{W}_i u_i \gamma^{1, 0}$, where $r_1 = \sum_{i \in \mathbb{Z}/s} a_i \gamma^{1, 0}$, with the digits $0 \leq a_i < p, a_i = (p - 1) - a_i$ and for all $i \in \mathbb{Z}/s$, $\varphi(u_i \gamma^{1, 0}) = i^{(1)}$

$L_2 = \oplus_{j \in \mathbb{Z}/s} \mathcal{W}_j \gamma^{2, 0}, F(L_2) = \sum_{j \in \mathbb{Z}/s} \mathcal{W}_j u_j \gamma^{2, 0}$, where $r_2 = \sum_{j \in \mathbb{Z}/s} b_j \gamma^{2, 0}$, with the digits $0 \leq b_j < p, b_j = (p - 1) - b_j$ and for all $j \in \mathbb{Z}/s$, $\varphi(u_j \gamma^{2, 0}) = j^{(2)}$

**Lemma 1.17.** For $\kappa = 1, 2$, $L_\kappa$ is isomorphic to the product of $s/s(r_\kappa)$ copies of the (simple) object $L(r_\kappa)$.

**Proof.** Take $\kappa = 1$. For $\gamma \in \mathbb{F}_{p^\nu}$ and $\tilde{i} \in \mathbb{Z}/s(r_1)$, let $m_i(\gamma) = \sum_{i \equiv \tilde{i} \mod S(r_1)} a_i \gamma^{1, 0}$ and $M(\gamma) = \sum_{i \equiv \tilde{i} \mod S(r_1)} \mathcal{W}_i m_i(\gamma) \subset L_1$. Then all $M(\gamma) = (M(\gamma), M(\gamma) \cap F(L_1), \varphi, N)$ with induced $\varphi$ and $N$ are subobjects of $L_1$ isomorphic to $L(r_1)$. If $\gamma_1, \ldots, \gamma_d$ is an $\mathbb{F}_{p^\nu(r_1)}$-basis of $\mathbb{F}_{p^\nu}$ then $M(\gamma_1) \times \cdots \times M(\gamma_d)$ is isomorphic to $L_1$. (Use that $d = s/s(r_1)$ and $\det(\sigma(\gamma_\lambda)) \neq 0$, where for a given $\tilde{i}$, $i$ is such that $i \equiv \tilde{i} \mod S(r_1)$ and $1 \leq i \leq d$).

If $L = (L, F(L), \varphi, N) \in L^{cr}_r$ then we shall use the same notation $L$ for the image $(L, F(L), \varphi)$ of $L$ under the forgetful functor from $L^{cr}_r$ to $L^{cr}_r$. Clearly, this forgetful functor induces a group homomorphism $\text{Ext}_{L^{cr}_r}(L_2, L_1) \rightarrow \text{Ext}_{L^{cr}_r}(L_2, L_1)$.

Suppose $L = (L, F(L), \varphi) \in \text{Ext}_{L^{cr}_r}(L_2, L_1)$. Consider a $\sigma(\mathcal{W}_1)$-linear section $S : l^{(2)}_j \rightarrow l^{(2)}_j, j \in \mathbb{Z}/s$, of the corresponding epimorphic map $\varphi(F(L)) \rightarrow \varphi(F(L_2))$. Then

a) $L = L_1 \oplus (\oplus_{j \in \mathbb{Z}/s} \mathcal{W}_j l^{(2)}_j)$

b) for all indices $j \in \mathbb{Z}/s$, there are unique elements $v_j \in L_1$, such that $F(L) = F(L_1) + \sum_{j \in \mathbb{Z}/s} \mathcal{W}_j (u_j \gamma^{2, 0} + v_j)$ and $\varphi(u_j \gamma^{2, 0} + v_j) = l^{(2)}_j$. 

**Documenta Mathematica 18 (2013) 547–619**
c) $F(L) \supset u^{p-1} L$ if and only if for all $j \in \mathbb{Z}/s$, $u^jv_j \in F(L_1)$;
d) if $S^\mathbf{t}(l_{ij}) \rightarrow l'_{ij} = l_j + \varphi(w_{j-1})$, where $j \in \mathbb{Z}/s$ and $w_{j-1} \in F(L_1)$, is another section of the epimorphism $\varphi(F(L)) \rightarrow \varphi(F(L_2))$ then for the corresponding elements $v'_j \in L_1$, $v'_j - v_j = w_j - u^b_j \varphi(w_{j-1})$.

The constructions from above items a)-d) can be summarized as follows.

**Lemma 1.18.** Let $Z(L_2, L_1) = \{(v_j)_{j \in \mathbb{Z}/s} \in L_1^a | u^b_jv_j \in F(L_1)\}$ be a subgroup in $L_1^a$ and let

$$B(L_2, L_1) = \{(w_j - u^b_j \varphi(w_{j-1}))_{j \in \mathbb{Z}/s} | w_j \in F(L_1)\}$$

be a subgroup of $Z(L_2, L_1)$. Then there is a natural isomorphism of abelian groups $Z(L_2, L_1)/B(L_2, L_1) \simeq \text{Ext}L_{s^L}(L_2, L_1)$.

**Proposition 1.19.** Any $L \in \text{Ext}L_{s^L}(L_2, L_1)$ appears from a system of factors $(v(j))_{j \in \mathbb{Z}/s} \in Z(L_2, L_1)$ satisfying the following normalization condition

(C1) if $v_j = \sum_{i,t} \gamma_{ijt} u^{i_1}t_1$ with $\gamma_{ijt} \in k$, then $\gamma_{ijb_j} = 0$.

**Proof.** Choose a section $S$ of the projection $\varphi(F(L)) \rightarrow \varphi(F(L_2))$ with the minimal set $\gamma(S) = \{(i, j, \tilde{b}_j) | \gamma_{ijb_j} \neq 0\}$. Suppose $\gamma(S) \neq \emptyset$ (otherwise, the proposition is proved) and let $(v(j))_{j \in \mathbb{Z}/s}$ be the corresponding system of factors.

Suppose $(i_0, j_0, b_{j_0}) \in \gamma(S)$ and $\gamma = \gamma_{i_0j_0b_{j_0}}$. Replace $(v(j))_{j \in \mathbb{Z}/s}$ by an equivalent system $(v'(j))_{j \in \mathbb{Z}/s}$ via the elements $w_j \in F(L_1)$ such that $w_j = 0$ if $j \neq j_0 - 1$ and $w_{j+1} = \sigma^{-1}((\gamma) u_{i_0}^{a_{i_0} - 1}l_{i_0}^{(1)} - 1)$.

If $v'_j = \sum_{i,t} \gamma'_{ijt} u^{i'_{ijt}}$ then

- $\gamma'_{i_0j_0b_{j_0}} = 0$;
- $\gamma'_{i_0-1, j_0-1, a_{i_0} - 1} = \sigma^{-1}(\gamma) + \gamma_{i_0-1, j_0-1, a_{i_0} - 1}$;
- for all remaining indices $\gamma'_{ijt} = \gamma_{ijt}$.

Then $\gamma(S') \subset \gamma(S) \setminus \{(i_0, j_0, \tilde{b}_{j_0})\}$ and the minimality condition for $S$ implies $\gamma(i_0 - 1, j_0 - 1, a_{i_0} - 1) = \gamma(S') \setminus \gamma(S)$. Therefore, $\tilde{a}_{i_0} - 1 = \tilde{b}_{j_0} - 1$, $\gamma_{i_0-1, j_0-1, a_{i_0} - 1} = 0$, $\gamma'_{i_0-1, j_0-1, b_{j_0} - 1} = \sigma^{-1}(\gamma)$, and the new section $S'$ again satisfies the minimality condition.

Repeating the above procedure we obtain for all $n \in \mathbb{Z}/s$, that $\tilde{a}_{i_0} - n = \tilde{b}_{j_0} - n$, that is $\tilde{r}_1(i_0) = \tilde{r}_2(j_0)$.

Choose $\beta \in k$ such that $\sigma^s(\beta) - \beta = \gamma$ and consider $w_j \in F(L_1)$ such that for all $0 \leq n < s$, $w_{j+n} = \sigma^n(\beta) u_{i_0}^{a_{i_0} - 1}l_{i_0}^{(1)}$. Then for the corresponding new system of factors $(v'(j))_{j \in \mathbb{Z}/s}$, where

$$v'_j = v_j + w_j - u^b_j \varphi(w_{j-1}) = \sum_{i,t} \gamma'_{ijt} u^{i'_{ijt}}$$

one has $\gamma'_{i_0j_0b_{j_0}} = 0$, and $\gamma_{ijt} = \gamma'_{ijt}$ if $(i, j, t) \neq (i_0, j_0, b_{j_0})$. This contradicts to the minimality condition for $S$. \qed
Proposition 1.20. Any $\mathcal{L} \in \text{Ext}^\omega_{\mathcal{L}}(\mathcal{L}_2, \mathcal{L}_1)$ can be described via a system of factors $(v_j)_{j \in \mathbb{Z}/s}$, satisfying the above condition (C1) and the normalization condition

(C2) the coefficients $\gamma_{ijt} = 0$ if $t > \tilde{a}_i$.

Proof. Suppose $v^{(0)} = (v_j)_{j \in \mathbb{Z}/s}$ is such that $v_{j_0} = \gamma u^{t_0}l_0^{(1)}$ with $\gamma \in \mathcal{K}$, $t_0 > \tilde{a}_{i_0}$ and for $j \neq j_0$, $v_j = 0$. It will be sufficient to prove that any such system of factors is trivial.

Take the elements $w_j^{(0)}$, $j \in \mathbb{Z}/s$, such that $w_{j_0}^{(0)} = -\gamma u^{t_0}l_0^{(1)}$ and $w_j^{(0)} = 0$ if $j \neq j_0$. Then the corresponding equivalent system $(v_j^{(1)})_{j \in \mathbb{Z}/s}$ is such that $v_j^{(1)} = 0$ if $j \neq j_0 + 1$, and $v_j^{(1)} = \gamma p u^{t_1}l_{j_0+1}$, where $t_1 = \tilde{b}_{j_0+1} + (t_0 - \tilde{a}_{i_0})p$. This implies that $t_1 > p > \tilde{a}_{i_0+1}, t_1 - \tilde{a}_{i_0+1} > t_0 - \tilde{a}_{i_0}$, and $t_1 - \tilde{a}_{i_0+1} > t_0 - \tilde{a}_{i_0}$ unless $\tilde{b}_{j_0+1} = 0, t_1 = p$ and $\tilde{a}_{i_0+1} = p - 1$.

Repeat this procedure by using for all $n \geq 0$, the appropriate elements $w_j^{(n)}$, $j \in \mathbb{Z}/s$, to obtain the equivalent systems of factors $(v_j^{(n)})_{j \in \mathbb{Z}/s}$ such that $v_j^{(n)} = 0$ if $j \neq j_0 + n$, and $v_j^{(n)} = \gamma p^n u^{t_n}l_{j_0+n}^{(1)}$.

If $(\tilde{r}_2, \tilde{r}_1, t_0) \neq (0, 1, p)$ then $t_n \to \infty$ and we can use the elements $w_j = \sum_{n \geq 0} w_j^{(n)}$, $j \in \mathbb{Z}/s$, to trivialize the original system of factors $v^{(0)}$.

If $(\tilde{r}_2, \tilde{r}_1, t_0) = (0, 1, p)$, we can trivialize $v^{(0)}$ via the elements $w_j$, $j \in \mathbb{Z}/s$, for which $0 \leq n < s$, $w_{j_0+n} = \kappa p^n u^{t_n}l_{j_0+n}^{(1)}$ and $\kappa \in \mathcal{K}$ such that $\sigma^s(\kappa) - \kappa = \gamma$.

\[ N(u^\tilde{b}_j l_j + v_j) \equiv \sum_{i, t} \gamma_{ijt}(\tilde{b}_j - t)u^{t_i^{(1)}} + u^\tilde{b}_j N(l_j) \text{mod} F(L). \]

The condition $\mathcal{L} \in \mathcal{L}_r^r$ implies that $N(u^\tilde{b}_j l_j + v_j) \in F(L) \text{mod} u^{2p}L$ and $N(l_j) \in u^p L \text{mod} u^{2p}L \subset F(L) \text{mod} u^{2p}L$. This means that all $(\tilde{b}_j - t)\gamma_{ijt} u^{t_i^{(1)}} \in F(L_1)$.

Therefore, for $t \neq \tilde{b}_j$, $\gamma_{ijt} u^{t_i^{(1)}} \in F(L_1))$, and $v_j \in F(L_1)$. The proposition is proved.
implies that \( \tilde{\kappa} \). Let

Now we can set for all indices \( \tilde{\kappa} \) and this implies that \( \tilde{\kappa} \). Proof. Suppose \( \tilde{\kappa} \) and \( \tilde{\kappa} \) is trivial, cf. the proof of Proposition 1.22. This

Let \( \tilde{\kappa} \) and suppose \( \tilde{\kappa} \) if \( \tilde{\kappa} \). Proposition 1.22. Any element \( \tilde{\kappa} \) can be obtained as a sum of \( \tilde{\kappa} \) and \( \tilde{\kappa} \) runs over the set of \( \tilde{\kappa} \)-admissible pairs and all coefficients \( \tilde{\kappa} \) in \( \tilde{\kappa} \).

The above proposition describes the subgroup \( \tilde{\kappa} \) of \( \tilde{\kappa} \). In particular, working modulo this subgroup we can describe the extensions in the whole category \( \tilde{\kappa} \) via the systems of factors \( \tilde{\kappa} \) such that \( \tilde{\kappa} \) satisfy the normalization conditions (C1) and

\[(C3) \text{ if } t \geq \tilde{\kappa} \text{ then } \tilde{\kappa} = 0. \]

Proposition 1.23. Suppose the system of factors \( \tilde{\kappa} \) satisfies the conditions (C1) and (C3). If it determines \( \tilde{\kappa} \) then:

a) \( \tilde{\kappa} = 0 \) if \( t < \tilde{\kappa} - 1 \);

b) \( \tilde{\kappa} = \tilde{\kappa} + 1 \) and there is an \( m_0 \in \mathbb{N} \) such that for all \( 1 \leq m < m_0 \), \( \tilde{\kappa} + m = \tilde{\kappa} + m_0 \) but \( \tilde{\kappa} + m_0 = \tilde{\kappa} + m_0 \), then \( \tilde{\kappa} = 0 \);

c) \( \tilde{\kappa} = \tilde{\kappa} + 1 \) and for all \( m \in \mathbb{N} / \mathbb{S} \), \( \tilde{\kappa} + m = \tilde{\kappa} + m_0 \) then \( \tilde{\kappa} = 0. \)

Proof. Suppose \( \tilde{\kappa} \) and \( \tilde{\kappa} \) describes the image of \( \tilde{\kappa} \) in \( \tilde{\kappa} \). By the definition of \( N \), \( uN(u(b_i + v_j)) \in \tilde{\kappa} \), and this implies that \( \tilde{\kappa} = 0 \) if \( t < \tilde{\kappa} - 1 \), \( t \neq \tilde{\kappa} \) (use congruence (1.5)). This proves a).

Now we can set for all indices \( i \) and \( j \), \( \tilde{\kappa} := \tilde{\kappa} \). Let \( \kappa \) be such that \( N(\kappa) = \sum \kappa j \mod p \) and suppose \( \kappa \neq 0 \) (this implies that \( \tilde{\kappa} \neq \tilde{\kappa} \)). For \( m > 0 \), consider the relations

\[(1.6) \quad N(\kappa j) = \varphi(uN(u(b_i + v_j) + \tilde{\kappa} + m)). \]
Varieties with Bad Reduction at 3 Only

If $m = 0$ then (1.6) implies $\kappa_{i+1,j+1} = \gamma_i^p (\tilde{b}_j - \tilde{a}_i + 1)$. Suppose that there is an $m_0 \geq 0$ such that for all $1 \leq m < m_0$, $\tilde{a}_{i+m} - 1 = \tilde{b}_j + m$ but $\tilde{a}_{i+m} - 1 \neq \tilde{b}_j + m_0$. Then (1.6) together with (1.5) (where $j$ is replaced by $j + m$) imply that for $1 \leq m < m_0$,

$$\kappa_{i+m+1,j+m+1} = r_{i+m,j+m} = \gamma_i^{p+1} (\tilde{b}_j - \tilde{a}_i + 1).$$

In particular, $N(l_{j+m_0}) \mod u^pL$ contains $l_{j+m_0}^{(1)}$ with the coefficient $\gamma_i^{p+1} (\tilde{b}_j - \tilde{a}_i + 1)$. Therefore, $uN(\tilde{b}_j^{i+m_0}l_{j+m_0} + v_{j+m_0}) \mod u^pL$ contains $l_{j+m_0}^{(1)}$ with the coefficient $u^{\tilde{b}_j^{i+m_0}+1} \gamma_i^{p+1} (\tilde{b}_j - \tilde{a}_i + 1)$. But this monomial must belong to $F(L_i)$.

This proves that if $\gamma_{ij} \neq 0$ then $\tilde{b}_{j+m_0} + 1 > \tilde{a}_{i+m_0}$.

Finally, suppose that for all $m \geq 1$, $\tilde{a}_{i+m} - 1 = \tilde{b}_j + m$. Then $\tilde{a}_i - 1 = \tilde{a}_{i+s} - 1 = \tilde{b}_j + s = \tilde{b}_j$ and $\gamma_{ij} = \gamma_i, \tilde{a}_s - 1 = \tilde{a}_{ij}, \tilde{b}_j = 0$. □

**Remark.** With notation from the proof of above proposition the elements $v_j = \sum_{1} \gamma_{ij} u \tilde{a}_i - 1 l_{i+1}^{(1)}$ determine a system of factors from $Z(L_2, L_1)$ if $\gamma_{ij} = 0$ when either $\tilde{a}_i = 0$ or $\tilde{b}_j = p - 1$ (in this case $v_j$ should belong to $F(L_i)$).

**Definition.** A pair $(i_0, j_0) \in (\mathbb{Z}/s)^2$ is $(r_1, r_2)_s$-admissible if:

- $\tilde{b}_{j_0} \neq p - 1$ and $\tilde{a}_{i_0} \neq 0$; cf. above remark;
- $\tilde{b}_{j_0} - 1 \neq \tilde{b}_{j_0};$
- there is an $m_0 = m_{st}(i_0, j_0) \in \mathbb{N}$ such that for $1 \leq m < m_0$, $\tilde{a}_{i_0+m} - 1 = \tilde{b}_{j_0+m}$ but $\tilde{a}_{i_0+m} - 1 < \tilde{b}_{j_0+m}.$

**Definition.** A pair $(i_0, j_0) \in (\mathbb{Z}/s)^2$ is $(r_1, r_2)_s^p$-admissible if $i_0 = 0$ and for all $m \in \mathbb{Z}/s$, $\tilde{a}_m - 1 = \tilde{b}_{j_0+m}.$

**Proposition 1.24.** a) If $(i_0, j_0)$ is an $(r_1, r_2)_s$-admissible pair then $r_1(i_0) + 1/(p - 1) > r_2(j_0);$ b) if $(0, j_0)$ is an $(r_1, r_2)_s^p$-admissible pair then $r_1 + 1/(p - 1) = r_2(j_0).$

**Proof.** a) Here for $1 \leq m < m_0$, $a_{i_0+m} + 1 = b_{j_0+m}$ and $a_{i_0+m} \geq b_{j_0+m}.$ Therefore,

$$r_1(i_0) + 1/(p - 1) > \sum_{1 \leq m \leq m_0} (a_{i_0+m} + 1)p^{-m} > \sum_{1 \leq m \leq m_0} b_{j_0+m}p^{-m} + \sum_{m > m_0} (p - 1)p^{-m} \geq r_2(j_0).$$

The part b) can be obtained similarly. □

Using the calculations from the proof of Proposition 1.23 we obtain the following two statements.

**Proposition 1.25.** Suppose $(i_0, j_0) \in (\mathbb{Z}/s)^2$ is $(r_1, r_2)_s$-admissible and $\gamma \in k$. Then there is a unique $E_s(i_0, j_0, \gamma) \in \text{Ext}_{\mathbb{Z}/s}(L_2, L_1)$ given by the system of factors $(v_j)_{j \in \mathbb{Z}/s}$ such that $v_{j_0} = \gamma a_{i_0} - 1 l_{i_0}^{(1)}$ and $v_j = 0$ if $j \neq j_0,$ and the map $N$, which is uniquely determined by the condition:
The following proposition gives the uniqueness property of the decomposition of any element $L \in \text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ into a sum of standard extensions.

**Proposition 1.27.** Any element $L \in \text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ appears as a unique sum of the standard extensions $E_{cr}(i, j, \gamma_{ij})$, $E_{st}(i, j, \gamma_{ij}^{st})$ and $E_{sp}(j, \gamma_{0j}^{sp})$, where all $\gamma_{ij}^{cr}$, $\gamma_{ij}^{st}$ are equal to 0 but $\gamma_{0j}^{sp} \neq 0$, resp. $\gamma_{ij}^{st} = 0$, $\gamma_{0j}^{sp} = 0$, if the corresponding pair of lower indices is not $(r_1, r_2)_{cr}$-admissible, resp. $(r_1, r_2)_{st}$-admissible, $(r_1, r_2)_{sp}$-admissible.

**Proof.** By Proposition 1.23, any $L \in \text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ can be decomposed as a sum of the above special extensions. To prove the uniqueness of such decomposition, assume that $L$ represents a trivial element of $\text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ and prove that all involved coefficients $\gamma_{ij}^{cr}$, $\gamma_{ij}^{st}$ and $\gamma_{0j}^{sp}$ are equal to 0.

The image of $L$ in $\text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ is given by the system of factors $(v_{ij}^{cr} + v_{ij}^{st})_{j \in \mathbb{Z}/s}$ such that

- $v_{ij}^{cr} = \sum_{i} \gamma_{ij}^{cr} u_{i} l_{i}^{(1)}$.
- $v_{ij}^{st} = \sum_{i} \gamma_{ij}^{st} u_{i} l_{i}^{(1)}$.

Let $w_{j} \in F(L_{1})$ be such that for all $j$, $v_{j} = w_{j} - \tilde{b}_{j} \varphi(w_{j-1})$. If $w_{j} \equiv \sum_{i} \kappa_{ij} u_{i} l_{i}^{(1)} \mod u F(L)$ with $\kappa_{ij} \in k$, then for all $i$ and $j$, $j > 1$,

$$
(1.7) \quad \gamma_{ij}^{cr} u_{i}^{\tilde{a}_{i}} + \gamma_{ij}^{st} u_{i}^{\tilde{a}_{i}-1} \equiv \kappa_{ij} u_{i}^{\tilde{a}_{i}} - \kappa_{i-1,j-1} u_{i}^{\tilde{b}_{j}} \mod u^{\tilde{a}_{i}+1}.
$$

Suppose $(i_0, j_0)$ is $(r_1, r_2)_{cr}$-admissible. Then $\tilde{a}_{i_0} - 1 \neq \tilde{b}_{j_0}$ and comparing the coefficients for $u^{\tilde{a}_{i_0}+1}$ in (1.7) we deduce that $\gamma_{i_0,j_0}^{cr} = 0$. Therefore, all $\gamma_{ij}^{cr} = 0$.

Suppose $(i_0, j_0)$ is $(r_1, r_2)_{st}$-admissible. Then for $m_0 = m_{cr}(i_0, j_0)$, $\tilde{a}_{i_0} \neq \tilde{b}_{j_0}$, $\tilde{a}_{i_0} + m = \tilde{b}_{j_0} + m$ if $1 \leq m < m_0$, and $\tilde{a}_{i_0} + m_0 > \tilde{b}_{j_0} + m_0$. Then (1.7) implies that $\gamma_{i_0,j_0}^{cr} = \kappa_{i_0,j_0}$, $\kappa_{i_0,m,j_0} + m = \kappa_{i_0,m-1,j_0} + m - 1$ for $1 \leq m < m_0$, and $\kappa_{i_0+m-1,j_0+m-1} = 0$. Therefore, $\gamma_{i_0,j_0}^{st} = 0$.

Finally, $L$ is the trivial element of the group $\text{Ext}^{1}(\mathcal{L}_2, \mathcal{L}_1)$ and, therefore, for all $j$, $N(l_{j}) \in u^{2} L$. Then from the description of standard extensions $E_{sp}(j, \gamma_{0j}^{sp})$ in Proposition 1.26 it follows that all $\gamma_{0j}^{sp} = 0$. \hfill $\Box$
2. The functor $CV^* : \mathcal{L}^* \to \text{CMF}$

2.1. The object $R_{st}^0 \in \mathcal{L}^*$. Let $R = \varprojlim (\bar{O}/p)_n$ be Fontaine's ring; it has a natural structure of $k$-algebra via the map $k \to R$ given by $\alpha \mapsto \varprojlim (\sigma^{-n}\alpha \mod p)$, where for any $\gamma \in k$, $[\gamma] \in W(k) \subset \bar{O}$ is the Teichmüller representative of $\gamma$. Let $m_R$ be the maximal ideal of $R$.

Choose $x_0 = (x_0^{(n)} \mod p)_{n \geq 0} \in R$ and $\varepsilon = (\varepsilon^{(n)} \mod p)_{n \geq 0}$ such that for all $n \geq 0$, $x_0^{(n+1)p} = x_0^{(n)}$ and $\varepsilon^{(n+1)p} = \varepsilon^{(n)}$ with $x_0^{(0)} = -p$, $\varepsilon^{(0)} = 1$ but $\varepsilon^{(1)} \neq 1$. We shall denote by $v_R$ the valuation on $R$ such that $v_R(x_0) = 1$.

Let $Y$ be an indeterminate.

Consider the divided power envelope $R(Y)$ of $R[Y]$ with respect to the ideal $(Y)$. If for $j \geq 0$, $\gamma_j(Y)$ is the $j$-th divided power of $Y$ then $R(Y) = \bigoplus_{j \geq 0} R\gamma_j(Y)$. Denote by $R_{st}$ the completion $\prod_{j \geq 0} R\gamma_j(Y)$ of $R(Y)$ and set, $\text{Fil}^p R_{st} = \prod_{i \geq 1} R\gamma_i(Y)$. Define the $\sigma$-linear morphism of the $R$-algebra $R_{st}$ by the correspondence $Y \mapsto x_0^{2p}Y$; it will be denoted below by the same symbol $\sigma$.

Introduce a $W_1$-module structure on $R_{st}$ by the $k$-algebra morphism $W_1 \to R_{st}$ such that $u \mapsto \iota(u) := x_0 \exp(-Y) = x_0 \sum_{j \geq 0} (-1)^j \gamma_j(Y)$. Set $F(R_{st}) = \sum_{0 \leq i < p} x_0^{p-1-i} R\gamma_i(Y) + \text{Fil}^p R_{st}$. Define the continuous $\sigma$-linear morphism of $R$-modules $\varphi : F(R_{st}) \to R_{st}$ by setting for $0 \leq i < p$, $\varphi(x_0^{p-1-i} \gamma_i(Y)) = \gamma_i(Y)(1 - (i/2)x_0^{2p}Y)$, and for $i \geq p$, $\varphi(\gamma_i(Y)) = 0$. Let $N$ be a unique $R$-differential of $R_{st}$ such that $N(Y) = 1$.

**Proposition 2.1.** a) If $a \in R_{st}$ and $b \in F(R_{st})$ then

$$\varphi(ab) = \sigma(a) \varphi(b) \mod x_0^{2p} R_{st};$$

b) $\varphi \mod x_0^{2p} R_{st}$ is a $\sigma$-linear morphism of $W_1$-modules;

c) for any $b \in R_{st}$ and $w \in W_1$, $N(\varphi(w)) = N(\varphi(w)) \mod x_0^{2p} R_{st}$;

d) for any $l \in F(R_{st})$, $uN(l) \in F(R_{st})$ and

$$N(\varphi(l)) = \varphi(uN(l)) \mod x_0^{2p} R_{st}.$$

**Proof.** a) It is sufficient to verify it for $a = Y$ and $b = x_0^{p-1-i} \gamma_i(Y)$, $0 \leq i < p$.

b) Use that the multiplication by $\sigma(u) = u^p$ comes as the multiplication by $\iota(u)^p = x_0^{p-1-i} \gamma_i(Y)$, $0 \leq i < p$.

c) Use that $N(\iota(u)) = -\iota(u)$.

d) It will be enough to check the identity for $l = x_0^{p-1-i} \gamma_i(Y)$ with $1 \leq i < p$.

Then $N(\varphi(l)) = \gamma_i(Y)(1 - (1/2)(i + 1)x_0^{2p}Y)$. On the other hand, $uN(l) = x_0^{p-1-i} \gamma_i(Y) \exp(-Y)$ and $\varphi(uN(l))$ is equal to

$$\gamma_i(Y) \left(1 - \frac{i - 1}{2} x_0^{2p}Y\right) \mod x_0^{2p}$$

\[\Box\]

Introduce a $\Gamma_F$-action on $R_{st} \mod x_0^{2p}/(p-1) R_{st}$ as follows.
For any $\tau \in \Gamma_F$, let $k(\tau) \in \mathbb{Z}$ be such that $\tau(x_0) = e^{k(\tau)}x_0$ and let $\log(1 + X) = X - X^2/2 + \cdots - X^{p-1}/(p-1)$ be the truncated logarithm. For any $\tau \in \Gamma_F$, define a linear map $\tau : R_{st} \to R_{st}$ by extending the natural action of $\tau$ on $R$ and setting for $\tau \in \Gamma_F$ and $j \geq 0$,

$$\tau(\gamma_j(Y)) := \sum_{0 \leq i \leq \min(j, p-1)} \gamma_{j-i}(Y)\gamma_i(\log \varepsilon).$$

Note that the cocycle relation $\varepsilon^{k(\tau_1)(\gamma_1\varepsilon)}^{k(\tau)} = \varepsilon^{k(\tau_1\tau)}$, where $\tau_1, \tau \in \Gamma_F$, implies the cocycle relation

$$k(\tau_1)\log \varepsilon + k(\tau)\log(\varepsilon) \equiv k(\tau_1\tau)\log \varepsilon \bmod x_0^{p^2/(p-1)}.$$ 

(Use that $\log(1 + X)^k \equiv k\log(1 + X) \bmod (X^p)$ and $\varepsilon \equiv 1 \bmod x_0^{p/(p-1)}$.) In addition, for any $k \in \mathbb{Z}$, the obvious congruence

$$(1 + X)^k = \exp(k\log(1 + X)) \equiv \exp(k\log(1 + X)) \bmod (X^p)$$

implies that for any $\tau \in \Gamma_F$, $\tau(x_0 \exp(-Y)) \equiv x_0 \exp(-Y) \bmod x_0^{p^2/(p-1)}$.

Therefore, the correspondences $\gamma_j(Y) \mapsto \tau(\gamma_j(Y))$ induce a $\Gamma_F$-action on $\mathcal{W}_1$-algebra $R_{st}$ mod $x_0^{p^2/(p-1)}$, which extends the natural $\Gamma_F$-action on $R$.

**Proposition 2.2.** For any $\tau \in \Gamma_F$,

a) $\tau(F(R_{st})) = F(R_{st})$;

b) for any $a \in F(R_{st})$, $\tau(\varphi(a)) \equiv \varphi(\tau(a)) \bmod x_0^{p^2/(p-1)}$;

c) for any $b \in R_{st}$, $\tau(N(b)) = N(\tau(b))$.

*Proof.* The proof is straightforward in cases a) and c). Part b) follows by direct calculation from the following Lemma. \qed

**Lemma 2.3.** $\sigma(\log \varepsilon)/x_0^{p^2/(p-1)} \equiv \log \varepsilon \bmod x_0^{p^2/(p-1)} R$.

*Proof.* Consider Fontaine’s element

$$t^+ = \log[\varepsilon] = \sum_{n \geq 1} (-1)^{n-1} \frac{([\varepsilon] - 1)^n}{n} = \sum_{m \in \mathbb{Z}} p^m[\eta_m] \in A_{cr}$$

where all $\eta_m \in R$. Then $t^+ \in \text{Fil}^1 A_{cr}$ and $\sigma t^+ = pt^+$. This implies for all $m \in \mathbb{Z}$, that $\eta_m = \sigma^{-m}\eta_0$.

Consider $\mathcal{H} \subset A_{cr}$ consisting of the elements of the form $\sum_{m \in \mathbb{Z}} p^m[r_m]$ such that for $m \leq 0$, $v_R(r_m) \geq p^2/(p-1)$ (this is automatic for $m \leq -2$), $v_R(r_1) \geq p^2/(p-1) - 1$ and $v_R(r_2) \geq p^2/(p-1) - 2$. Then $\mathcal{H}$ is an additive subgroup in $A_{cr}$.

Verify that

- for all $n \geq p$, $([\varepsilon] - 1)^n/n \in \mathcal{H}$.

*Documenta Mathematica* 18 (2013) 547–619
Indeed, the congruence \([ε] ≡ 1 + [a_0] \mod pW(R)\) (where \(a_0 = ε - 1\)) implies that \([ε] = \lim_{m→∞}(1 + [σ^{-m}a_0])p^m\). Therefore,

\[
[ε] - 1 = \sum_{m \geq 0} [a_m]p^m = [a_0] \left(1 + \sum_{m \geq 1} p^m[a_m]\right),
\]

where \(v_R(a_m) = p^{1-m}/(p - 1)\), if \(v_R(1) = -1\) and \(v_R(2) = -1 - 1/p\). If \(n \not\equiv 0 \mod p\) then \(([ε] - 1)^n ≡ [a_0n] + p[a_1n] + p^2[a_2n] \mod p^3W(R)\) with \(v_R(a_0n) = v_R(a_1n) + 1 = v_R(a_2n) + 2 =pn/(p - 1)\). This proves that \(([ε] - 1)^n/n \in \mathcal{H}\) for all \(n \not\equiv 0 \mod p, n > p\).

As for all remaining \(n \geq p\), just note that for all \(M \geq 1,\)

\[
([ε] - 1)^{p^M} ≡ [a_0]^{p^M}(1 + p^{M+1}[b_1] + p^{M+2}[b_{2M}]) \mod p^{M+3}W(R),
\]

where \(v_R(b_{2M}) = -2\).

The above calculations mean that \(t^+ ≡ \log[ε] \mod \mathcal{H}\). Therefore, if

\[
\log[ε] = [ω_0] + p[ω_1] + p^2[ω_2] \mod p^3W(R),
\]

then \(<ω_0 = \log[ε] ≡ ω_0 \mod x_0^{p^2/(p - 1)}R, ω_1 ≡ ω_1 ≡ ω_0 ≡ ω_1 \mod x_0^{p^2/(p - 1)}R, ω_2 ≡ ω_2 \mod x_0^{p^2/(p - 1)}R,\>

and \(\log[ε] \mod x_0^{p^2/(p - 1)}R, t^+ = \log[ε] \mod x_0^{p^2/(p - 1)}R,\) the lemma is proved.

By above results we can introduce \(\mathcal{R}_*^{\mathcal{L}} = (\mathcal{R}_0^\mathcal{L}, F(\mathcal{R}_0^\mathcal{L}), \varphi, N) \in \mathcal{L}_*\), where \(\mathcal{R}_0^\mathcal{L} = R_0 \otimes \mathcal{M}_R \otimes \mathcal{F}(\mathcal{R}_0^\mathcal{L})\) and \(F(\mathcal{R}_0^\mathcal{L}) = F(\mathcal{R}_0^\mathcal{L}) \mod x_0^{p^2}N\) with induced \(\sigma\)-linear map \(\varphi\) and \(\mathcal{W}_1\)-differentiation \(N\). The above defined \(\Gamma_F\)-action on \(R_0 \otimes \mathcal{M}_R \otimes \mathcal{F}(\mathcal{R}_0^\mathcal{L})\) respects the structure of \(\mathcal{R}_0^\mathcal{L}\) as an object of the category \(\mathcal{L}_*\). In our setting the filtered Galois module \(\mathcal{R}_0^\mathcal{L}\) plays a role of Fontaine’s ring \(\mathcal{L}_1\).

2.2. The functor \(\mathcal{V}^*\). If \(\mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}_*\) then the triple \((L, F(L), \varphi)\) is an object of \(\mathcal{L}_*\) which will be denoted below by the same symbol \(\mathcal{L}\).

**Definition.** Let \(\mathcal{R}^\mathcal{L} = (R_0^\mathcal{L}, F(R_0^\mathcal{L}), \varphi) \in \mathcal{L}_*\), where \(R_0^\mathcal{L} = R_0 \otimes \mathcal{M}_R \otimes \mathcal{F}(\mathcal{R}_0^\mathcal{L})\) and \(F(R_0^\mathcal{L}) = F(\mathcal{R}_0^\mathcal{L}) \mod x_0^{p^2}N\) with induced \(\sigma\)-linear map \(\varphi\) and \(\mathcal{W}_1\)-differentiation \(N\). If \(f \in \mathcal{V}^*(\mathcal{L})\) and \(i \geq 0\), introduce the \(k\)-linear morphisms \(f_i : \mathcal{L} \rightarrow R_i^\mathcal{L}\) such that for any \(l \in L, f(l) = \sum_{i \geq 0} f_i(l)\gamma_i(Y)\). The correspondence \(f \mapsto f_0\) gives the homomorphism of abelian groups \(pr_0 : \mathcal{V}^*(\mathcal{L}) \rightarrow \mathcal{V}^0(\mathcal{L}) := \text{Hom}_{\mathcal{L}_0^*}(\mathcal{L}, R_0^\mathcal{L})\).
PROPOSITION 2.4. pr⁰ is isomorphism of abelian groups.

Proof. Clearly, pr⁰ is additive. Suppose f ∈ Ker pr⁰. Then for all i ⩾ 0 and
l ∈ L, fᵢ(l) = fᵢ(Nᵢ(l))) = 0, i.e. f = 0.
Suppose g ∈ Hom₂₋₁(L, R⁰). This means that g : L → R⁰ is a σ-linear
morphism of W₁-modules, g(F(L)) ⊂ F(R⁰) and for any l ∈ F(L), g(ϕ(l)) =
((g(l)/x₀⁻¹)ᵢ)ₚ.
Set for any l ∈ L, f(l) = g(l) + g(Nl)γ₁(Y) + · · · + g(Nᵢl)γᵢ(Y) + · · · Then for
any l ∈ L, f(N(l)) = N(f(l)) and our Proposition is implied by the following
Lemma.

LEMMA 2.5. a) For any l ∈ L, f(u[l]) = x₀ exp(−Y)f(l);
b) for any l ∈ F(L), ϕ(f(l)) = f(ϕ(l)).

Proof of Lemma. a) For any l ∈ L, f(u[l]) = ∑₀,₀ g(Nᵢ(u[l]))γᵢ(Y) =
x₀ ∑₀,₀ g(Nᵢ(u[l]))γᵢ(Y) =
x₀ ∑₀,₀ (−1)ᵢ)γᵢ(Y)γᵢ(Y) = x₀ exp(−Y)f(l).
b) Let l ∈ L. Prove by induction on i ⩾ 1 that
Nᵢ(ϕ(l)) = ϕ(u[Nᵢ](l)) = −i(i − 1)₂uᵢ(ϕ(uᵢ−¹Nᵢ−¹(l)) + ϕ(uᵢNᵢ(l)).
Then
\[ g(Nᵢ(ϕ(l))) = \frac{−i(i − 1)}{2} x₀ \left( \frac{g(uᵢ−¹Nᵢ−¹(l))}{x₀⁻¹} \right) + \left( \frac{g(uᵢNᵢ(l))}{x₀⁻¹} \right) \]
and f(ϕ(l)) is equal to ∑₀,₀ g(Nᵢ(ϕ(l)))γᵢ(Y) =
\[ \sum₀,₀ \left( \frac{g(Nᵢl)}{x₀⁻¹} \right) \left( γᵢ(Y) - \frac{i(i + 1)}{2} x₀²γᵢ+₁(Y) \right) = ϕ(f(l)). \]

COROLLARY 2.6. a) If rkวล L = s then |วล(ς)| = pᵢ;
b) the correspondence /us(ς) induces an exact functor υ from ς to the
category of F_p[ς]-modules.

Proof. a) Proceed as in [1, 3]. Suppose the structure of the filtered ϕ-module
ς is given by a choice of a W₁-basis m₁, ..., mᵢ of F(L) and non-degenerate
matrix A ∈ Ms(W₁) such that (m₁, ..., mᵢ) = (ϕ(m₁), ..., ϕ(mᵢ)). Let
X = (X₁, ..., Xᵢ) be a vector with s independent variables and let R₀ =
Frac R. Consider the quotient Aς of the polynomial ring R₀[X] by the ideal
generated by the coordinates of the vector (X A)ₚ − x₀ᵖ⁻¹X. (For a matrix
C the matrix Cₚ is obtained by raising all elements of C to p-power.)
Then Aς is etale R₀-algebra of rank pᵢ (use that (uᵢ−¹Iₖ)A⁻¹ ∈ Ms(W₁))
and all its $\hat{R}_0$-points give rise to elements of the group $\text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \mathcal{R})$, where $\mathcal{R} = (R, x_0^{p-1}R, \varphi) \in \mathcal{E}_0$ is such that for any $r \in R$, $\varphi(x_0^{p-1}r) = r^p$. It remains to note that $\varphi |_{x_0^{p-1}m_R}$ is nilpotent, by Lemma 1.5, the natural projection $\mathcal{R} \to \mathcal{R}_0$ induces bijection from $\text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \mathcal{R})$ to $\text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \mathcal{L}) \subseteq \mathcal{L}$. Then it is strict if and only if $f$ is monomorphism ($\text{Ker} f$) is nilpotent. For $\mathcal{R}_0 = (R_0, x_0^{p-1}R_0, \varphi)$ of $R_0$, there is a natural projection $\mathcal{R}_0 \to \hat{\mathcal{R}}_0$ in $\mathcal{E}_0$ and for any $\mathcal{L} \in \mathcal{E}_0$, $\text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \mathcal{R}_0) = \text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \hat{\mathcal{R}}_0)$. This implies the following description of the $\hat{\mathcal{L}}_F$-modules $V^*(\mathcal{L})$ where $\mathcal{L} \in \mathcal{E}_0$ (use the identification $\text{pr}_0$ of Proposition 2.4). 

**Corollary 2.7.**

$$V^*(\mathcal{L}) = \left\{ \sum_{0 \leq i \leq p} N^*(f_0) \gamma_i(Y) \mod \hat{J} \mid f_0 \in \text{Hom}_{\mathcal{E}_0}(\mathcal{L}, \mathcal{R}_0) \right\}$$

**Remark.** a) In the above description of $V^*(\mathcal{L})$, for any $l \in \mathcal{L}$, $N^*(f_0)(l) = f_0(N(l))$. In addition, all $N^*(f_0) \gamma_i(Y)$ depend just on $N_1 = N \mod u^p L$. 
b) If $\mathcal{L} \in \mathcal{E}_0$ then in the above Corollary we can replace $\mathcal{R}_0$ and $\hat{J}$ by $\mathcal{R}_0 = (R/x_0^0R, x_0^0R, \varphi) \in \mathcal{E}_0$ and the ideal $\hat{J}_1 = \sum_{0 \leq i \leq p} R x_0^0 \gamma_i(Y) + \text{Fil} R_0^p$. In particular, for unipotent modules the whole theory can be developed in the context of $k[u]/u^p$-modules.

### 2.3. THE CATEGORY $\text{CMGF}_\Gamma$ AND THE FUNCTOR $\text{CV}^*$.

**Definition.** The objects of the category $\text{CMGF}_\Gamma$ are the triples $\mathcal{H} = (H, H^0, j)$, where $H, H^0$ are finite $\mathbb{Z}_p[\Gamma_F]$-modules, $\Gamma_F$ acts trivially on $H^0$ and $j : H \to H^0$ is an epimorphic map of $\mathbb{Z}_p[\Gamma_F]$-modules. If $\mathcal{H}_1 = (H_1, H_0^1, j_1) \in \text{CMGF}_\Gamma$, then $\text{Hom}_{\text{CMGF}_\Gamma}(\mathcal{H}_1, \mathcal{H})$ consists of the couples $(f, f^0)$, where $f : H_1 \to H$ and $f^0 : H_0^1 \to H^0$ are morphisms of $\Gamma_F$-modules such that $jf = f^0 j_1$.

The category $\text{CMGF}_\Gamma$ is pre-abelian, cf. Appendix A, and its objects have a natural group structure. In particular, with above notation, $\text{Ker}(f, f^0) = (\text{Ker} f, j_1(\text{Ker} f))$ together with the natural embedding to $\mathcal{H}_1$. Similarly, $\text{Coker}(f, f^0) = (H/f(H_1), H^0/j(f(H_1)))$. For example, the map $(\text{id}, 0) : (H, H) \to (H, 0)$ has the trivial kernel and cokernel. In addition, the monomorphism $(f_1, f_1^0) : \mathcal{H}_1 \to \mathcal{H}$ is strict if and only if $f_1 \circ \text{Ker}j_1 = f_1(\text{Ker} j) \cap \text{Ker} j$. Suppose $\mathcal{H}_2 = (H_2, H_0^2, j_2)$ and $(f_2, f_2^0) : \mathcal{H} \to \mathcal{H}_2$ is an epimorphism. Then it is strict if and only if $f_2^0$ induces epimorphic map from $\text{Ker} j$ to $\text{Ker} j_2$. In $\text{CMGF}_\Gamma$ we can use formalism of short exact sequences and the corresponding 6-terms $\text{Hom}_{\text{CMGF}_\Gamma} = \text{Ext}_{\text{CMGF}_\Gamma}$ exact sequences, cf. Appendix A.
2.4. A criterion. Suppose \( \mathcal{L} \in \mathcal{L}^* \) and \( i^{ct} : \mathcal{L}^{ct} \rightarrow \mathcal{L} \) is the maximal etale subobject. Then \( CV^* : \mathcal{L}^* \rightarrow CM\Gamma_F \) is the functor such that \( CV^*(\mathcal{L}) = (V^*(L), V^*(L^{ct}), V^*(i^{ct})) \).

The simple objects in \( CM\Gamma_F \) are of the form either \( (H, 0, 0) \), where \( H \) is a simple \( \mathbb{Z}_p[\Gamma_F] \)-module, or \( (\mathbb{F}_p, \mathbb{F}_p, id) \), where \( \mathbb{F}_p \) is provided with the trivial \( \Gamma_F \)-action. In this context it will be very convenient to use the following formalism.

For \( s \in \mathbb{N} \), consider Serre’s fundamental characters \( \chi_s : \Gamma_F \rightarrow k^* \). Here for \( \tau \in \Gamma_F \), \( \chi_s(\tau) = (\tau x_s) / x_s \mod x_s^m \), where \( x_s \in R \) is such that \( x_s^{p^s-1} = x_0 \). If \( \chi \) is any continuous (1-dimensional) character of \( \Gamma_F \) then there are \( s, m \in \mathbb{N} \) such that \( 0 < m \leq p^s - 1 \) and \( \chi = \chi_s^m \). Set \( r(\chi) = m / (p^s - 1) \). Then \( r(\chi) \) depends only on \( \chi \) and the correspondence \( \chi \mapsto r(\chi) \) gives a bijection from the set of all continuous (1-dimensional) characters of \( \Gamma_F \) with values in \( k^* \) to the set \( [0, 1]_p \cup \{0\} \).

For \( r \in [0, 1]_p \), \( r \neq 0 \), introduce the \( \Gamma_F \)-module \( \mathbb{F}(r) \) such that \( \mathbb{F}(r) = \mathbb{F}_{p(r)} \), where \( p(r) \) is the period of the \( p \)-digit expansion of \( r \), cf. Subsection 1.2, with the \( \Gamma_F \)-action given by the character \( \chi \) such that \( r(\chi) = r \). We have:

- \( \mathbb{F}(r) \) are simple \( \mathbb{Z}_p[\Gamma_F] \)-modules;
- \( \Gamma_F \)-modules \( \mathbb{F}(r_1) \) and \( \mathbb{F}(r_2) \) are isomorphic if and only if there is an \( n \in \mathbb{Z} \) such that \( r_1 = r_2(n) \);
- any simple \( \mathbb{Z}_p[\Gamma_F] \)-module is isomorphic to some \( \mathbb{F}(r) \).

It will be natural to set \( \mathcal{F}(r) := (\mathbb{F}(r), 0, 0) \) for all \( r \in [0, 1]_p \), and to set separately \( \mathcal{F}(0) := (\mathbb{F}_p, \mathbb{F}_p, id) \).

With above notation we have the following property, where the objects \( \mathcal{L}(r) \) were introduced in Subsection 1.3.

**Proposition 2.8.** For any \( r \in [0, 1]_p \), \( CV^*(\mathcal{L}(r)) = \mathcal{F}(r) \).

**Proof.** The proof goes along the lines of Subsection 4.2 of [1], cf. also the beginning of Subsection 2.4 below. \( \square \)

### 2.4. A criterion.

Suppose \( \mathcal{L}_1, \mathcal{L}_2 \) are given in notation of Subsection 1.4 and \( q = p^s \). Then for \( i = 1, 2 \), \( V^*(\mathcal{L}_i) = V_i \) are 1-dimensional vector spaces over \( \mathbb{F}_q \) with \( \Gamma_F \)-action given by the character \( \chi_i : \Gamma_F \rightarrow k^* \) such that \( r(\chi_i) = r_i \).

(Note that \( (q-1)r_i \in \mathbb{Z} \) and, therefore, \( \chi_i(\Gamma_F) \subset \mathbb{F}_q^* \)). Choose \( \pi_s \in \mathcal{F}_s \) such that \( \pi_s^{q-1} = -p \).

Then \( F_s = \mathcal{F}(\pi_s) \) is a tamely ramified extension of \( F \) of degree \( q-1 \) and all points of \( V_i \) are defined over \( F_s \). We can identify \( V_i \) with the \( \mathbb{F}_s[\Gamma_F] \)-module \( \mathbb{F}_s[\pi_s^{(q-1)r_i}] \subset \mathcal{O}/p\mathcal{O} \), where \( \pi_s = \pi_s \mod p \). These identifications allow us to fix the points \( h_{\alpha}^{0} := \pi_s^{(q-1)r_i} \in V_i \) and to identify \( V_i \) with the \( \Gamma_F \)-module \( \{\alpha h_{\alpha}^{0} | \alpha \in \mathbb{F}_q^* \} \).

Suppose \( h_1 \in V_1 \). Define the homomorphism

\[
F_{h_1} : \text{Ext}_{\mathbb{F}_s[\Gamma_F]}(V_1, V_2) \rightarrow Z^1(\Gamma_F, \mathbb{F}_q) = \text{Hom}(\Gamma_F, \mathbb{F}_q),
\]

where \( \Gamma_F = \text{Gal}(\bar{F}/F_s) \), as follows. If \( V \in \text{Ext}_{\mathbb{F}_s[\Gamma_F]}(V_1, V_2) \) and \( h \in V \) is a lift of \( h_1 \) then for any \( \tau \in \Gamma_F \), \( F_{h_1}(V)(\tau) = a_\tau \in \mathbb{F}_q \), where \( \tau h - h = a_\tau h_{\alpha}^{0} \).
Clearly, $F_{h_1}(V)$ does not depend on a choice of $h$ and it is the zero function if and only if the projection $V \to V_1$ admits a $\Gamma_F$-equivariant section. In other words, we have the following criterion.

**Proposition 2.9.** $V$ is the trivial extension if and only if for all $h_1 \in V_1$, one has $F_{h_1}(V) = 0$.

2.5. Galois Modules $V^*(E_{cr}(i_0, j_0, \gamma))$. Suppose we have an object $L = (L, F(L), \varphi, N)$ of the category $\mathcal{L}_{\Gamma}$. Then there is a special $\sigma(W_1)$-basis $l_1, \ldots, l_s$ of $\varphi(F(L))$ such that for some integers $0 \leq c_1, \ldots, c_s < p$ and a matrix $A \in GL_r(k)$, the elements $\varphi^{c_i}l_1, \ldots, \varphi^{c_s}l_s$ form a $W_1$-basis of $F(L)$ and $(\varphi(\varphi^{c_1}l_1), \ldots, \varphi(\varphi^{c_s}l_s)) = (l_1, \ldots, l_s)A$.

For $1 \leq i \leq s$, set $c_i = (p - 1) - c_i$. The following Proposition is a special case of Corollary 2.7 (remind that $R^0 = R/x_0^p\mathcal{M}_R$).

**Proposition 2.10.** With above notation, $V^*(L)$ is the $\mathbb{F}_p[\Gamma_F]$-module of all $(\theta_1, \ldots, \theta_s)$ mod $x_0^p\mathcal{M}_R$ in $(R^0)^s$ such that

$$(\theta_1/x_0^{c_1}, \ldots, \theta_s/x_0^{c_s}) = (\theta_1, \ldots, \theta_s)A.$$  

**Remark.** In [1, 2] it was proved (in the context of the Fontaine-Laffaille theory) that the family of $\mathbb{F}_p[\Gamma_F]$-modules $V^*(L)$, where $L \in \mathcal{L}_{\Gamma}$, coincides with the family of all killed by $p$ subquotients of crystalline representations of $\Gamma_F$ with weights from $[0, p)$. This result can be also extracted from Subsection 4, where we establish that the family of $\mathbb{F}_p[\Gamma_F]$-modules $V^*(L)$, where $L \in \mathcal{L}_{\Gamma}$, coincides with the family of all killed by $p$ subquotients of semi-stable representations of $\Gamma_F$ with weights from $[0, p)$.

For an $(r_1, r_2)_{\gamma,r}$-admissible pair $(i_0, j_0) \in (\mathbb{Z}/s)^2$ and $\gamma \in k$, use the description of $E_{cr}(i_0, j_0, \gamma)$ from Subsection 1.4. Then by Corollary 2.7, $V = V^*(E_{cr}(i_0, j_0, \gamma))$ is identified with the additive group of all taken modulo $x_0^p\mathcal{M}_R$ solutions in $R$ of the following system of equations

$$X^{(1)}_i/x_0^{c_i} = X^{(1)}_{i+1}, \quad \text{for all } i \in \mathbb{Z}/s;$$

$$X_{j+1}^p/x_0^{p \delta_j} = X_{j+1} - \delta_{j,0} \gamma^p X^{(1)}_{i+1}, \quad \text{for all } j \in \mathbb{Z}/s.$$  

Note that the first group of equations describes $V_1 = V^*(L_1)$ and the correspondences $X^{(1)}_i \mapsto 0$ and $X_j \mapsto X^{(2)}_j$ with $i, j \in \mathbb{Z}/s$, define the map $V \to V_2$, where $V_2 = V^*(L_2)$ is associated with all taken modulo $x_0^p\mathcal{M}_R$ solutions in $R$ of the equations $X^{(2)}_{j+1}/x_0^{p \delta_j} = X^{(2)}_{j+1}, j \in \mathbb{Z}/s$. As it was noted in Subsection 2.2, the corresponding $\Gamma_F$-action on $V, V_1$ and $V_2$ comes from the natural $\Gamma_F$-action on $R^0$.

Take $x_s \in R$ such that $x_2^{-1} = x_0$ and $x_s \mapsto \pi_s \text{mod } p$ under the natural identification $R/x_0^p\mathcal{M}_R \simeq O/pO$. (This identification is given by the correspondence $r = \lim_{n \to \infty} (r_n \text{mod } p) \mapsto X^{(1)}_n$.) For $i, j \in \mathbb{Z}/s$, set $x^{(i)}_{r_1} := x^{(q^{-1} r_1)}_r$ and $x^{(i)}_{r_2} := x^{(q^{-1} r_2)}_r$, and introduce the variables $Z^{(1)}_i = x^{(1)}_{r_1} X^{(1)}_i$, $Z^{(2)}_j = x^{(1)}_{r_2} X^{(2)}_j$. Then the elements of $V$ appear as
the taken modulo \( m_R \) solutions in \( R_0 := \text{Frac}(R) \) of the following system of equations
\[
\begin{align*}
Z_i^{(1)} p &= Z_{i+1}^{(1)}, & \text{for all } i \in \mathbb{Z}/s; \\
Z_j^{(2)} &= Z_{j+1}, & \text{for all } j \neq j_0 + 1;
\end{align*}
\]
\[
Z_{j_0+1} - Z_{j_0+1}^{(2)} = \gamma^p Z_{i+1}^{(1)} p^r \pi_0 \quad (r_1(i_0) - r_2(j_0))
\]
Note that for the points \( h_1 \in V_1 \) and \( h_2 \in V_2 \) chosen in Subsection 2.4, one has \( Z_i^{(1)}(h_1^0) = Z_i^{(2)}(h_2^0) = 1 \), where \( i \in \mathbb{Z}/s \).
Suppose \( \alpha \in \mathbb{F}_q \) and \( h_1 = ah_0^0 \in V_1 \).
Let \( F_s = k((x_s)) \subset R_0 = \text{Frac} R \). The field-of-norms functor gives a natural embedding of the absolute Galois group \( \Gamma_{F_s} \) of \( F_s \) into \( \Gamma_{F_r} \), where \( F_s = F(\pi_s) \).
Then the restriction \( F_{h_1}(V)|_{\Gamma_{F_r}} \) of the cocycle
\[
\{ F_{h_1}(V)(\tau) = A_{\tau,\alpha}(i_0, j_0, \gamma) \in \mathbb{F}_q \mid \tau \in \Gamma_{F_r} \}
\]
from Subsection 2.4 can be described as follows.
Let \( U \in R_0 \) be such that \( U - U^q = \gamma x_{0}^{(i_0) - r_2(j_0)} \). Then for any \( \tau \in \Gamma_{F_r} \),
\[
\sigma^{\tau}(A_{\tau,\alpha}(i_0, j_0, \gamma)) = \sigma^{\tau}(\alpha)(\tau(U) - U)
\]
and therefore
\[
A_{\tau,\alpha}(i_0, j_0, \gamma) = \sigma^{\tau}(\alpha)\sigma^{-\gamma}(\tau U - U).
\]
The following Lemma is an immediate consequence of the definition of \((r_1, r_2, \alpha)\)-admissible pairs.

**Lemma 2.11.** With above notation let \( C = -(q-1)(r_1(i_0) - r_2(j_0)) \). Then \( C \)
is a prime to \( p \) integer and \( 1 \leq C \leq q - 1 \).

2.6. **Galois Modules** \( V^* (E_{st}(i_0, j_0, \gamma)) \). For an \((r_1, r_2, \alpha)\)-admissible pair \((i_0, j_0) \in (\mathbb{Z}/s)^2\) and \( \gamma \in k \), use the description of \( E_{st}(i_0, j_0, \gamma) \) from Subsection 1.5.

By Subsection 2.2, \( V = V^* (E_{st}(i_0, j_0, \gamma)) \) is identified (as an abelian group)
with the solutions \( \{(X_i^{(1)} \mid i \in \mathbb{Z}/s), \{X_j \mid j \in \mathbb{Z}/s\} \} \in R^{2s} \) of the following system of equations
\[
\begin{align*}
X_i^{(1)} p / x_0^{p a_i} &= X_{i+1}^{(1)}, & \text{for all } i \in \mathbb{Z}/s; \\
X_j^{p} / x_0^{p b_j} + \delta_{j_0} \gamma^p X_0^{(1)} p / x_0^{p a_{i_0} + p} &= X_{j+1}, & \text{for all } j \in \mathbb{Z}/s
\end{align*}
\]
The structure of \( V \) as an element of \( \text{Ext} F_s(\Gamma_{F_s})(V_1, V_2) \) can be described along the lines of Subsection 2.5. The action of \( \Gamma_{F_s} \) on \( V \) comes from the natural \( \Gamma_{F_s} \)-action on \( \mathbb{R}^{2s}_{st} \), and the embedding of \( V \) into \( (R^{0}_{st})^{2s} \) given by the following correspondences:
- if \( i \in \mathbb{Z}/s \) then \( X_i^{(1)} \mapsto X_i^{(1)} \bmod x_0^{p a_i} R; \)
- if \( j \notin \{j_0 + 1, \ldots, j_0 + m_0\} \) then \( X_j \mapsto X_j \bmod x_0^{p a_i} R; \)
- for \( 1 \leq m \leq m_0 \), \( X_{j_0 + m} \mapsto X_{j_0 + m} + \gamma^p(b_{j_0} - a_{i_0} + 1)X_{i_0 + m}^{(1)} Y \mod x_0^{p a_i} R. \)

Similarly to Subsection 2.5, introduce new variables by the relations \( Z_i^{(1)} = x_0^{p r_1(i)} X_i^{(1)}, \ Z_i = x_0^{-r_2(i)} X_i \) and \( Z_i^{(2)} = x_0^{-r_2(i)} X_i^{(2)} \), \( i \in \mathbb{Z}/s \), and rewrite
system of equations (2.1) in the following form:

\[
\begin{align*}
Z_i^{(1)p} &= Z_{i+1} \quad &\text{for all } i \in \mathbb{Z}/s; \\
Z_j^q &= Z_{j+1} \quad &\text{for all } j \notin j_0 + 1; \\
Z_{j_0+1} - Z_{j_0+1}^q &= \gamma^p Z_i^{(1)} \beta_0^q (r_1(i_0) - r_2(j_0) - 1)
\end{align*}
\]

If \( \alpha \in \mathbb{F}_q \) and \( h_1 = \alpha h_0^q \in V_1 \), then the restriction to \( \Gamma_{F} \) of the cocycle \( \{ F_{h_1}(V)(\tau) = A_{\tau,\alpha}(i_0, j_0, \gamma) \mid \tau \in \Gamma_{F_1} \} \) can be described as follows. Let \( U \in R_0 \) be such that

\[
U - U^q = \gamma^p Z_i^{(1)} \beta_0^q (r_1(i_0) - r_2(j_0) - 1).
\]

Then for any \( \tau \in \Gamma_{F_1} \), \( \sigma^j_{h_1}(A_{\tau,\alpha}(i_0, j_0, \gamma)) = \sigma^j_{h_0}(\alpha)(\tau U - U) \).

Thus

\[
A_{\tau,\alpha}(i_0, j_0, \gamma) = \sigma^j_{h_0}(\alpha) \sigma^j_{h_0}(\tau U - U).
\]

The following Lemma is a direct consequence of the definition of \((r_1, r_2)_m\)-admissible pairs, cf. also Proposition 1.24.

**Lemma 2.12.** Let \( C = -(q - 1)(r_1(i_0) - r_2(j_0) - 1). \) Then \( C \) is a prime to \( p \) integer such that \( 1 \leq C < (q - 1)(1 + 1/(p - 1)) \).

### 2.7. Galois Modules \( E_{sp}(j_0, \gamma) \)

In this subsection \((0, j_0)\) is some \((r_1, r_2)_m\)-admissible pair (i.e. \( r_1 + 1/(p - 1) = r_0(j_0) \)) and \( \gamma \in \mathbb{F}_q \). Then \( V = \mathcal{V}^s(E_{sp}(j_0, \gamma)) \) is identified as an abelian group with the solutions

\[
\{(X_i^{(1)} \mid i \in \mathbb{Z}/s), (X_j^{(2)} \mid j \in \mathbb{Z}/s)\} \in R^{2s}
\]

of the following system of equations

\[
\begin{align*}
X_i^{(1)p} / X_i^{(1)} &= X_{i+1}^{(1)} \quad &\text{for all } i \in \mathbb{Z}/s, \\
X_j^{(2)p} / X_j^{(2)} &= X_{j+1}^{(2)} \quad &\text{for all } j \in \mathbb{Z}/s.
\end{align*}
\]

The corresponding \( \Gamma_{F}\)-action comes from the natural \( \Gamma_{F}\)-action on \( R_0^{1} \), and the embedding of \( V \) into \((R_0^{1})^{2s}\) given by the following correspondences:

- if \( i \in \mathbb{Z}/s \) then \( X_i^{(1)} \mapsto X_i^{(1)} \mod x_0^{p_1} m_R \);
- if \( m \in \mathbb{Z}/s \) then \( X_{j_0 + m}^{(2)} \mapsto X_{j_0 + m}^{(2)} + \gamma^m X_i^{(1)} Y \mod x_0^{p_2} m_R \).

If \( \alpha \in \mathbb{F}_q \) and \( h_1 = \alpha h_0^q \in V_1 \) then the cocycle

\[
\{ F_{h_1}(V)(\tau) = A_{\tau,\alpha}^{sp}(j_0, \gamma) \mid \tau \in \Gamma_{F_1} \}
\]

can be described as follows. Note that the point \( h_1 \) corresponds to the collection

\[
\{(\sigma^i(\alpha)x_0^{pr_1(i)} \mid i \in \mathbb{Z}/s), \{\sigma^i_{h_0}(\alpha) x_0^{pr_1(i-j_0)} Y | i \in \mathbb{Z}/s\} \}
\]

Then for \( \tau \in \Gamma_{F_1}, \) \( \tau(h_1) \) corresponds to the collection

\[
\{(\sigma^i(\alpha)x_0^{pr_1(i)} \mid i \in \mathbb{Z}/s), \{\sigma^i_{h_0}(\alpha) x_0^{pr_1(i-j_0)} Y + k(\tau) \log \varepsilon | i \in \mathbb{Z}/s\} \}
\]

Therefore, \( \tau(h_1) - h_1 \) corresponds to the collection

\[
\{0 \mid i \in \mathbb{Z}/s\}, \{\sigma^i h_0(\alpha) x_0^{pr_2(i)} k(\tau) \mid i \in \mathbb{Z}/s\},
\]

which corresponds to \( \sigma^i_{h_0}(\alpha) h_0^{pr_2} \). Therefore, \( A_{\tau,\alpha}^{sp}(j_0, \gamma) = \sigma^i_{h_0}(\alpha) k(\tau) \).

Notice that for any \( \tau \in \Gamma_{F_1} \subset \Gamma_{F_1} \), \( A_{\tau,\alpha}^{sp}(j_0, \gamma) = 0 \).

**Documenta Mathematica 18 (2013) 547–619**
2.8. Fully faithfulness of $CV^*$.

In this subsection we prove the following important property.

**Proposition 2.13.** The functor $CV^*$ is fully faithful.

**Proof.** We must prove that for all $L_1, L_2 \in L^*$, the functor $CV^*$ induces a bijective map

$$\Pi(L_1, L_2) : \text{Hom}_{L^*}(L_2, L_1) \to \text{Hom}_{CM^*}(CV^*(L_1), CV^*(L_2)).$$

By induction on lengths of composition series for $L_1$ and $L_2$ it will be sufficient to verify that for any two simple objects $L_1$ and $L_2$:

- $\Pi(L_1, L_2)$ is bijective;
- the functor $CV^*$ induces injective map

$$\text{EII}(L_1, L_2) : \text{Ext}_{L^*}(L_2, L_1) \to \text{Ext}_{CM^*}(CV^*(L_1), CV^*(L_2)).$$

The first fact has been already checked in Subsection 2.3.

In order to verify the second property, notice that for any two objects $L_1, L_2 \in L^*$, the natural map

$$\text{Ext}_{CM^*}(CV^*(L_1), CV^*(L_2)) \to \text{Ext}_{CM^*}(V^*(L_1), V^*(L_2))$$

is injective. Therefore, we can prove injectivity of $\text{EII}(L_1, L_2)$ on the level of functor $V^*$. In addition, for $n_1, n_2 \in \mathbb{N}$, $\text{Ext}_{L^*}(L_2^{n_1}, L_1^{n_2}) = \text{Ext}_{L^*}(L_2, L_1)^{n_1/n_2}$ (the formation of $\text{Ext}$ is compatible with direct sums). So, by Lemma 1.17, we can replace $L_1$ and $L_2$ by the objects introduced in Subsection 1.5 (where they are denoted also by $L_1$ and $L_2$).

By Proposition 1.27, any element of $\text{Ext}_{L^*}(L_2, L_1)$ appears as a sum of standard extensions of the form $E_{cr}(i, j, \gamma_{ij})$, $E_{st}(i, j, \gamma_{ij})$ and $E_{sp}(j, \gamma_{ij}^{sp})$. Here:

a) $(i, j) \in (\mathbb{Z}/s)^2$ is either $(r_1, r_2)_{cr}$-admissible or $(r_1, r_2)_{sp}$-admissible and all $\gamma_{ij} \in k$; b) $j \in \mathbb{Z}/s$ is such that $(0, j)$ is $(r_1, r_2)_{sp}$-admissible and $\gamma_{ij}^{sp} \in \mathbb{F}_q$.

**Remark.** A couple $(i, j)$ can’t be both $(r_1, r_2)_{cr}$-admissible and $(r_1, r_2)_{st}$-admissible, but it can be $(r_1, r_2)_{cr}$-admissible and $(r_1, r_2)_{sp}$-admissible at the same time.

By Subsections 2.5-2.7, we can attach to these standard extensions the 1-cocycles $A_{r, \alpha}(i, j, \gamma_{ij})$ and $A_{r, \alpha}^{sp}(j, \gamma_{ij}^{sp})$, where $\tau \in \Gamma_{F^*}$. It remains to prove that the sum of these cocycles is trivial only if all corresponding coefficients $\gamma_{ij}$ and $\gamma_{ij}^{sp}$ are equal to 0.

First, we need the following lemma.

**Lemma 2.14.** Suppose for all $(i, j) \in (\mathbb{Z}/s)^2$, the elements $U_{ij} \in R_0 = \text{Frac } R$ are such that $U_{ij} = U_{ij}^{q} = \gamma_{ij} x_i\overline{C}_i$, where all $\gamma_{ij} \in k$ and all $C_i$ are prime to $p$ natural numbers. For $\tau \in \Gamma_{F^*}$, let $B_{\tau}(i, j, \gamma_{ij}) = \tau(U_{ij}) - U_{ij} \in \mathbb{F}_q$. If for all $\alpha \in \mathbb{F}_q$ and all $\tau \in \Gamma_{F^*}$,

$$\sum_{i,j \in \mathbb{Z}/s} \sigma^{i-j}(\alpha)\sigma^{-j} B_{\tau}(i, j, \gamma_{ij}) = 0$$

(2.2)
then all $\gamma_{ij} = 0$.

Proof of Lemma. For different prime to $p$ natural numbers $C_{ij}$ the extensions $\mathcal{F}_s(U_{ij})$ behave independently. Therefore, we can assume that all $C_{ij} = C$ are the same.

Let $j_0 = j_0(j)$ be such that $0 \leq j_0 < s$ and $j_0 \equiv -j \mod s$. Then (2.2) means that for any $\alpha \in \mathbb{F}_q$,

$$B_\alpha := \sum_{i,j \in \mathbb{Z}/s} \sigma^{i-j}(\alpha)\sigma^{j_0}(U_{ij}) \in \mathbb{F}_s.$$ 

Then

$$B_\alpha - B^0_\alpha = \sum_{j \in \mathbb{Z}/s} \left( \sum_{i \in \mathbb{Z}/s} \sigma^{i-j}(\alpha)\gamma_{ij}^{-p} \right) x^{-p\alpha}.$$ 

Looking at the Laurent series of $B_\alpha \in \mathbb{F}_s$ we conclude that all $B_\alpha \in \mathbb{F}_q$. This means that for all $j \in \mathbb{Z}/s$ and $\alpha \in \mathbb{F}_q$, $\sum_{i \in \mathbb{Z}/s} \sigma^i(\alpha)\gamma_{ij} = 0$ and, therefore, all $\gamma_{ij} = 0$. The lemma is proved.

Now suppose that for all $\alpha \in \mathbb{F}_q$ and $\tau \in \Gamma_F$, the sum of cocycles $A_{\tau,\alpha}(i,j,\gamma_{ij})$ and $A^p_{\tau,\alpha}(i,j,\gamma_{ij}^p)$ is zero. Restrict this sum to the subgroup $\Gamma_F$. Then all $\gamma_{ij}$ will disappear and by above Lemma 2.14 all $\gamma_{ij} = 0$. So, for all $\tau \in \Gamma_F$ and $\alpha \in \mathbb{F}_q$, $\sum_{j \in \mathbb{Z}/s} \sigma^{-j}(\alpha)\gamma_{ij}^p = 0$, and this implies that all $\gamma_{ij}^p = 0$.

Corollary 2.15. The functor $\mathcal{V}^*$ is fully faithful on the subcategories of unipotent objects $\mathcal{L}^u$ and of connected objects $\mathcal{L}^c$.

Proof. Indeed, on both categories the map $\Pi(\mathcal{L}_1, \mathcal{L}_2)$ is already bijective on the level of functor $\mathcal{V}^*$.

2.9. Ramification estimates. Suppose $\mathcal{L} \in \mathcal{L}^u$ and $H = \mathcal{V}^*(\mathcal{L})$. For any rational number $v \geq 0$, denote by $\Gamma_F^{(v)}$ the ramification subgroup of $\Gamma_F$ in upper numbering, [22].

Proposition 2.16. If $v > 2 - 1/p$ then $\Gamma_F^{(v)}$ acts trivially on $H$.

A proof can be obtained along the lines of the paper [17] (which adjusts Fontaine’s approach from [14]). Alternatively, one can apply author’s method from [3]: if $\tau \in \Gamma_F^{(v)}$ with $v > 2 - 1/p$ then there is an automorphism $\psi$ of $R$ such that $\psi(x_0) = \tau(x_0)$ and $\psi$ induces the trivial action on $H$; therefore we can assume that $\tau$ comes from the absolute Galois group of $k((x_0))$ and the characteristic $p$ approach from [3] gives the ramification estimate which coincides with the required by the theory of field-of-norms.

Corollary 2.17. If $\tilde{F}$ is the common field-of-definition of points of $\mathbb{F}_p[\Gamma_F]$-modules $\mathcal{V}(\mathcal{L})$ for all $\mathcal{L} \in \mathcal{L}^u$, then $v_p(D(\tilde{F}/F)) < 3 - \frac{1}{p}$, where $D(\tilde{F}/F)$ is the different of the field extension $\tilde{F}/F$.
3. The ring $S$. Let $v = a + p \in W$ and let $S$ be the $p$-adic closure of the divided power envelope of $W$ with respect to the ideal generated by $v$. Use the same symbols $\sigma$ and $N$ for natural continuous extensions of $\sigma$ and $N$ from $W$ to $S$. For $i \geq 0$, denote by $\text{Fil}^i S$ the $i$-th divided power of the ideal $(v)$ in $S$. Then for $0 \leq i < p$, there are $\sigma$-linear morphisms $\phi_i = \sigma/p^i : \text{Fil}^i S \rightarrow S$.\footnote{Note that $\phi_0 = \sigma$ and agree to use the notation $\phi$ for $\phi_{p - 1}$. One can see also that $S$ is the $p$-adic closure of $W(k)[v_1, v_2, \ldots, v_n, \ldots]$, where $v_0 = v$ and for all $n \geq 0$, $v_{n+1}/p = v_n$.}

Consider the ideals $m_S = (p, v, v_1, \ldots, v_n, \ldots)$, $I = (p, v_1, v_2, \ldots)$ and $J = (p, v_1 v, v_2, \ldots, v_n, \ldots)$ of $S$. Then

- $m_S$ is the maximal ideal in $S$;
- $I = \text{Fil}^p S + pS \supset J$;
- $\varphi(I) \subset S$ and $\varphi(J) \subset pS$;
- $\varphi(v_i - 1) = -v_1 (\text{mod } J)$ and $\varphi(v_i) \equiv 1 (\text{mod } J)$.

3.2. The ring of semi-stable periods $\hat{A}_{st}$. Let $R$ be Fontaine’s ring and let $x_0, \varepsilon \in R$ be the elements chosen in Subsection 2.1. Denote by $A_{cr}$ the Fontaine crystalline ring. It is the $p$-adic closure of the divided power envelope of $W(R)$ with respect to the ideal $([x_0] + p)$ of $W(R)$, where $[x_0] \in W(R)$ is the Teichmüller representative of $x_0$. Then for $i \geq 0$, $\text{Fil}^i A_{cr}$ is the $i$-th divided power of the ideal $([x_0] + p)$ in $A_{cr}$. Denote by $\sigma : A_{cr} \rightarrow A_{cr}$ the natural morphism induced by the $p$-th power on $R$. Then for $0 \leq i < p$, there are $\sigma$-linear maps $\phi_i = \sigma/p^i : \text{Fil}^i A_{cr} \rightarrow A_{cr}$. We shall often use the simpler notation $\varphi = \phi_{p - 1}$ and $F(A_{cr}) = \text{Fil}^{p - 1} A_{cr}$.

Notice that $A_{st}$ is provided with the natural continuous $\Gamma_F$-action.

Let $X$ be an indeterminate. Then $\hat{A}_{st}$ is the $p$-adic closure of the ring $A_{cr}[\gamma_i(X) \mid i \geq 0] \subset A_{cr}[X] \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$, where for all $i \geq 0$, $\gamma_i(X) = X^{i!}$.\footnote{The ring $\hat{A}_{st}$ has the following additional structures:
- the $S$-module structure given by the natural $W(k)$-algebra structure and the correspondence $u \mapsto [x_0]/(1 + X)$;
- the ring endomorphism $\sigma$, which is the extension of the above defined endomorphism $\sigma$ of $A_{cr}$ via the condition $\sigma(X) = (1 + X)^p - 1$;
- the continuous $A_{cr}$-derivation $N : A_{st} \rightarrow A_{st}$ such that $N(X) = X + 1$;
- for any $i \geq 0$, the ideal $\text{Fil}^i \hat{A}_{st}$, which is the closure of the ideal $\sum_{i_1 + i_2 \geq i} (\text{Fil}^{i_1} A_{cr}) \gamma_{i_2}(X)$;
- the action of $\Gamma_F$, which is the extension of the $\Gamma_F$-action on $A_{cr}$ such that for all $\tau \in \Gamma_F$, $\tau(X) = [\varepsilon]^{k(\tau)}(X + 1) - 1$. Here all $k(\tau) \in \mathbb{Z}_p$ are such that $\tau(x_0) = \varepsilon^{k(\tau)} x_0$.
}

Note that for $0 \leq m < p$, $\sigma(\text{Fil}^m \hat{A}_{st}) \subset p^m \hat{A}_{st}$ and, as earlier, we can set $\phi_m = p^{-m} \sigma|_{\text{Fil}^m \hat{A}_{st}}$ and introduce the simpler notation $\varphi = \phi_{p - 1}$ and $F(\hat{A}_{st}) = \text{Fil}^{p - 1} \hat{A}_{st}$.

\footnote{Documenta Mathematica 18 (2013) 547–619}
3.3. Construction of semi-stable representations of $\Gamma_F$ with weights from $[0, p]$. For $0 \leq m < p$, consider the category $\mathcal{S}_m$ of quadruples $\mathcal{M} = (M, \text{Fil}^m M, \phi_m, N)$, where $\text{Fil}^m M \subset M$ are $S$-modules, $\phi_m : \text{Fil}^m M \to M$ is a $\sigma$-linear map and $N : M \to M$ is a $W(k)$-linear endomorphism such that for any $s \in S$ and $m \in M$, $N(sx) = N(s)x + sN(x)$.

The morphisms of the category $\mathcal{S}_m$ are $S$-linear morphisms commuting with the corresponding morphisms $\phi_m$ and $N$. Notice that for $0 \leq m < p$, $\mathcal{S}_m$ has a natural structure of the object of the category $\mathcal{S}_m$. As earlier, we shall use the simpler notation $\phi = \phi_{p-1}$ and $F(M) = \text{Fil}^{p-1} M$.

For $0 \leq m < p$, the Breuil category $\mathcal{S}_m$ of strongly divisible $S$-modules of weight $\leq m$ is a full subcategory of $\mathcal{S}_m$ consisting of the objects $\mathcal{M} = (M, \text{Fil}^m M, \phi_m, N)$ such that

1. $M$ is a free $S$-module of finite rank;
2. $(\text{Fil}^m S) M \subset \text{Fil}^m M$;
3. $(\text{Fil}^m M) \cap p M = p\text{Fil}^m M$;
4. $\phi_m(\text{Fil}^m M)$ spans $M$ over $S$;
5. $N\phi_m = p\phi_m N$;
6. $(\text{Fil}^1 S) N(\text{Fil}^m M) \subset \text{Fil}^m M$.

For $\mathcal{M} \in \mathcal{S}_m$, let $T_{st}^* (\mathcal{M})$ be the $\Gamma_F$-module of all $S$-linear and commuting with $\phi_m$ and $N$, maps $f : M \to \mathcal{A}_{st}$ such that $f(\text{Fil}^m M) \subset \text{Fil}^m \mathcal{A}_{st}$. Then one has the following two basic facts:

- $T_{st}^* (\mathcal{M})$ is a continuous $\mathbb{Z}_p [\Gamma_F]$-module without $p$-torsion, its $\mathbb{Z}_p$-rank equals $\text{rk}_S M$, and $V_{st}^* (\mathcal{M}) = T_{st}^* (\mathcal{M}) \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$ is semi-stable $\Gamma_F$-module with Hodge-Tate weights from $[0, m]$;

- any semi-stable representation of $\Gamma_F$ with Hodge-Tate weights from $[0, m]$, $0 \leq m < p$, appears in the form $V_{st}^* (\mathcal{M})$ for a suitable $\mathcal{M} \in \mathcal{S}_m$.

By Theorem 1.3 [6] these facts follow from the existence of strongly divisible lattices in $S \otimes W F$-modules associated with weakly admissible $(\phi_0, \hat{\mathbb{N}})$-modules with filtration of length $m$. Breuil proved this for all $m \leq p - 2$ but his method can be easily extended to cover the case $m = p - 1$ as well, cf. also [7].

3.4. The category $\mathcal{L}_f$. In this section we introduce $W$-analogues of Breuil’s $S$-modules from the category $\mathcal{S}_{p-1}$ and prove that they can be also used to construct semi-stable representations of $\Gamma_F$ with Hodge-Tate weights from $[0, p)$.

**Definition.** Let $\mathcal{L}$ be the category of $\mathcal{L} = (L, F(L), \varphi, N_S)$, where $L \supset F(L)$ are $W$-modules, $\varphi : F(L) \to L$ is a $\sigma$-linear morphism of $W$-modules and $N_S : L \to L_S := L \otimes_W S$ is such that for all $w \in W$ and $l \in L$, $N_S(wl) = N(w)l + (w \otimes 1)N_S(l)$. For $L_1 = (L_1, F(L_1), \varphi, N_S) \in \mathcal{L}$, the morphisms $\text{Hom}_W (\mathcal{L}, \mathcal{L}_1)$ are $W$-linear $f : L \to L_1$ such that $f(F(L)) \subset F(L_1)$, $f\varphi = \varphi f$ and $fN_S = N_S(f \otimes 1)$.
Let $\mathcal{A}_s = (\hat{A}_s, F(\hat{A}_s), \varphi, N_S)$, where $N_S = N \otimes 1$. Then $\mathcal{A}_s$ is an object of the category $\hat{\mathcal{L}}$.

Suppose $\mathcal{L} = (L, F(L), \varphi, N_S) \in \hat{\mathcal{L}}$.

Set $L_S := L \otimes_{W} S$, $F(L_S) = (F(L) \otimes 1)S + (L \otimes 1)\text{Fil}^P S$, and $\varphi_S : F(L_S) \longrightarrow F(L_S)$ is a unique $\sigma$-linear map such that $\varphi_S|_{F(L) \otimes 1} = \varphi \otimes 1$ and for any $s \in \text{Fil}^P S$ and $l \in L$, $\varphi_S(l \otimes s) = (\varphi(v^{p-1}l) \otimes 1)\varphi(s)/\varphi(v^{p-1})$.

**Definition.** Denote by $\mathcal{L}^f$ the full subcategory in $\hat{\mathcal{L}}$ consisting of the quadruples $\mathcal{L} = (L, F(L), \varphi, N_S)$ such that

- $L$ is a free $W$-module of finite rank;
- $v^{p-1}L \subset F(L)$, $F(L) \cap pL = pF(L)$ and $L = \varphi(F(L)) \otimes_{\sigma W} W$;
- for any $l \in F(L)$, $vN_S(l) \in F(L_S)$ and $\varphi_S(vN(l)) = cN_S(\varphi(l))$, where $c = 1 + v^p/p$.

It can be easily seen that for $\mathcal{L} = (L, F(L), \varphi, N_S) \in \mathcal{L}^f$ and the map $N = N_S \otimes 1 : L_S \longrightarrow L_S$, the quadruple $\mathcal{L}_S = (L_S, F(L_S), \varphi, N)$ is the object of the category $S_{p-1}$.

The main result of this Subsection is the following statement.

**Proposition 3.1.** For any $\mathcal{M} = (M, F(M), \varphi, N) \in S_{p-1}$, there is an $\mathcal{L} = (L, F(L), \varphi, N_S) \in \mathcal{L}^f$ such that $\mathcal{M} = \mathcal{L}_S$.

**Corollary 3.2.** a) If $\mathcal{L} \in \mathcal{L}^f$ and $T^{st}_{\mathcal{L}}(\mathcal{L}) = \text{Hom}_{\mathcal{L}}(\hat{\mathcal{L}}, \hat{\mathcal{A}}_{st})$ with the induced structure of $\mathbb{Z}_p[\Gamma_F]$-module then $V^{st}_{\mathcal{L}}(\mathcal{L}) = T^{st}_{\mathcal{L}}(\mathcal{L}) \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$ is a semi-stable $\mathbb{Q}_p[\Gamma_F]$-module with Hodge-Tate weights from $[0, p)$ and $\dim_{\mathbb{Q}_p} V^{st}_{\mathcal{L}}(\mathcal{L}) = \text{rk}_{W} L$.

b) For any semi-stable $\mathbb{Q}_p[\Gamma_F]$-module $V^{st}_{\mathcal{L}}$ with Hodge-Tate weights from $[0, p)$, there is an $\mathcal{L} \in \mathcal{L}^f$ such that $V^{st}_{\mathcal{L}} \simeq V^{st}_{\mathcal{L}}(\mathcal{L})$.

**Proof of Proposition 3.1.** Let $d$ be a rank of $M$ over $S$. If $L \subset M$ is a free $W$-submodule of rank $d$ and $M$ is generated by the elements of $L$ over $S$ we say that $L$ is $W$-structural (with respect to $M$).

Let $F(L) = F(M) \cap L$.

**Lemma 3.3.** If $L$ is $W$-structural for $M$ then

a) $F(L) \supset v^{p-1}L$;

b) $F(L) \cap pL = pF(L)$;

c) $F(L)$ is a free $W$-module of rank $d$.

**Proof.** a) $v^{p-1}L \subset (\text{Fil}^{p-1}S)M \cap L \subset F(M) \cap L = F(L)$.

b) $F(L) \cap pL = L \cap F(M) \cap pL = F(M) \cap pL = F(M) \cap pM \cap pL = pF(M) \cap pL = pF(L)$.

c) $F(L)$ has no $p$-torsion. Therefore, it will be sufficient to prove that $F(L)/pF(L)$ is a free $k[[\nu]]$-module of rank $d$. Consider the following natural embeddings of $k[[\nu]]$-modules

$L/pL \supset F(L)/pF(L) \supset v^{p-1}L/pv^{p-1}L \simeq L/pL$.
(Use b) and that $pl \cap v^{p-1}L = pv^{p-1}L$.) It remains to note that $L/pL$ is free of rank $d$ over $k[[v]]$.

The Lemma is proved. \hfill \Box

Suppose $L$ is $W$-structural for $M$.

**Lemma 3.4.** If $L$ is $W$-structural then $\varphi(F(L))$ spans $M$ over $S$.

**Proof.** The equality $S = W + \text{Fil}_p S$ implies that $M = L + (\text{Fil}_p S)L = L + (\text{Fil}_p S)M$. Therefore,

$$F(M) = F(M) \cap L + (\text{Fil}_p S)M = F(L) + (\text{Fil}_p S)L$$

(use that $F(M) \supset (\text{Fil}_p S)M$) and in notation of Subsection 3.1 one has

$$F(M) = F(L) + v(L) + JM.$$  

This implies that $\varphi(F(L)), \varphi(v(L))$ and $\varphi(JM)$ span $M$ over $S$. But for any $l \in L, \varphi(v(L)) = \varphi(v_1)/(\varphi(v^{p-1}) = (1 - v_1)^{-1}(v^{p-1}) \equiv \varphi(v^{p-1}) \mod mS.$ For similar reasons, $\varphi(JM) \subset pM \subset mS.$ This means that $\varphi(F(L))$ spans $M$ modulo $mS.$ The lemma is proved. \hfill \Box

By above lemma it remains to prove the existence of a $W$-structural $L$ for $M$ such that $\varphi(F(L)) \subset L$.

Let $\phi_0$ be a $\sigma$-linear endomorphism of the $S$-module $M \in S_{p-1}$ such that for all $m \in M, \phi_0(m) = \varphi(v^{p-1})m/\varphi(v^{p-1})$. Clearly, $\phi_0(mS) \subset mS$ and, therefore, it induces a $\sigma$-linear endomorphism $\sigma_0$ of the $k$-vector space $M_k = M/mS$.  

**Lemma 3.5.** Suppose $n \in \mathbb{Z}_{\geq 0}, L$ is $W$-structural and $\varphi(F(L)) \subset L + p^nM$. Then there is a $W$-structural $L'$ for $M$ such that $\varphi(F(L')) \subset L' + p^nJM$.  

**Proof.** Denote by $F(L)_k$ the image of $F(L)$ in the $k$-vector space $M/mS = L/(mS \cap W)L = L_k$. Let $s = \dim_k F(L)_k$, then $s \leq d = \dim_k L_k$. Choose a $W$-basis $e^{(1)}, \ldots, e^{(d)}$ of $L$ and a $W$-basis $f^{(1)}, \ldots, f^{(d)}$ of $F(L)$ such that

- $1 \leq i \leq s, f^{(i)} = e^{(i)}$ and for $s < i \leq d, f^{(i)} \in vL$.

It will be convenient to use the following vector notation; $\bar{e} = (\bar{e}_1, \bar{e}_2)$, where $\bar{e}_1 = (e^{(1)}, \ldots, e^{(s)})$ and $\bar{e}_2 = (e^{(s+1)}, \ldots, e^{(d)})$, and $\bar{f} = (f_1, f_2)$, where $f_1 = \bar{e}_1$ and $f_2 = (f^{(s+1)}, \ldots, f^{(d)})$.

Then in obvious notation one has $(\bar{e}_1, \bar{f}_2) = (\bar{e}_1, \bar{e}_2)C$, where $C \in \text{GL}_d(S)$. Clearly, $C \equiv C_0 + p^n v_1 C_1 \mod p^nJ$ with $C_0 \in \text{GL}_d(W)$ and $C_1 \in M_d(W)$. Clearly, $\varphi(F(L)) \subset L + p^nJM$ iff $C_1 \equiv 0 \mod mS$. Choose $\bar{g} = (\bar{g}_1, \bar{g}_2) \in L^d$ and set

$$\bar{e}_1' = (e^{(1)}, \ldots, e^{(s)}) = e_1 + p^n(v_1 - v^{p-1})\bar{g}_1$$

$$\overline{e}_2' = (e^{(s+1)}, \ldots, e^{(d)}) = e_2 + p^n(v_1 - v^{p-1})\bar{g}_2$$

Clearly, the coordinates of $\bar{e}' = (\bar{e}_1', \bar{e}_2')$ give an $S$-basis of $M$ and we can introduce the structural $W$-module $L' = \sum e^{(i)}$ for $M$.  

*Documenta Mathematica* 18 (2013) 547–619
Prove that the elements $e^{(i)}$, $1 \leq i \leq s$, and $f^{(i)}$, $s < i \leq d$, generate $F(L') \mod p^n JM$. Indeed, we have

$$L + p^n JM = L' + p^n IM$$

and this implies that the image $F(L)_k$ of $F(L)$ in $L_k$ coincides with its analogue $F(L')_k$. In addition, for $1 \leq i \leq s$,

$$e^{(i)} \in L' \cap (F(L) + p^n IM) \subset L' \cap F(M) = F(L').$$

Therefore, it would be sufficient to prove that $(vL) \cap F(L') \mod p^n JM$ is generated by the images of $ve^{(i)}$, $1 \leq i \leq s$, and $f^{(s+1)}, \ldots, f^{(d)}$. But relation (3.1) implies that $vL + p^n JM = vL' + p^n JM$ and

$$(vL') \cap F(L') \mod p^n JM = (vL) \cap F(L) \mod p^n JM.$$ 

It remains to note that for $1 \leq i \leq s$, $ve^{(i)} \equiv ve^{(i)} \mod p^n JM$.

Therefore, we can define special bases for $L'$ and $F(L')$ by the relations $f_1 = e_1$ and $f'_2 = f_2$ and obtain that

$$(\varphi(f'_1), \varphi(f'_2)) = (\varphi(f_1), \varphi(f_2)) + p^n v_1(\sigma_0 \bar{g}_1, 0) \mod p^n JM$$

and

$$(\varphi(f'_1), \varphi(f'_2)) \equiv (e'_1, e'_2)C_0 + p^n v_1(\bar{g}_1, \bar{g}_2)C_0 + p^n v_1((e_1, e_2)C_1 - (\bar{g}_1, \bar{g}_2)C_0 + (\sigma \bar{g}_1, 0)) \mod p^n JM$$

So, $\varphi(F(L')) \subset L' + p^n JM$ if and only if there is an $\bar{g} = (\bar{g}_1, \bar{g}_2) \in L^d$ such that $(\sigma_0 \bar{g}_1, 0) \equiv (\bar{g}_1, \bar{g}_2)C_0 + \bar{h} \mod (m_S \cap W)L$, where $\bar{h} = (e_1, e_2)C_1 \in L$ and $C_0 \mod m_S \in GL_d(k)$. The existence of such vector $\bar{g}$ is implied by Lemma 3.6 below.

**Lemma 3.6.** Suppose $V$ is a d-dimensional vector space over $k$ with a $\sigma$-linear endomorphism $\sigma_0 : V \rightarrow V$ and $\bar{a} = (\bar{a}_1, \bar{a}_2) \in V^d$, where $\bar{a}_1 \in V^s$ and $\bar{a}_2 \in V^{d-s}$. Then for any $C \in GL_d(k)$ there is an $\bar{g} = (\bar{g}_1, \bar{g}_2) \in V^d$ with $\bar{g}_1 \in V^s$ and $\bar{g}_2 \in V^{d-s}$ such that

$$\begin{align*}
(\sigma_0 \bar{g}_1, 0) & = \bar{g}C + \bar{a}.
\end{align*}$$

**Proof.** Let $C^{-1} = \begin{pmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{pmatrix}$ with the block matrices of sizes $s \times s$, $(d-s) \times s$, $s \times (d-s)$ and $(d-s) \times (d-s)$. Then the equality (3.2) can be rewritten as

$$\begin{align*}
(\sigma_0 \bar{g}_1)D_{11} &= \bar{g}_1 + \bar{a}_1' \\
(\sigma_0 \bar{g}_1)D_{21} &= \bar{g}_2 + \bar{a}_2'
\end{align*}$$

where $(\bar{a}_1', \bar{a}_2') = \bar{a}C^{-1}$. Clearly, it will be sufficient to solve the first equation in $\bar{g}_1$, but this is a special case of Lemma 1.1.

**Lemma 3.7.** Suppose $n \geq 0$ and $L$ is $W$-structural for $M$ such that $\varphi(F(L')) \subset L + p^n JM$. Then there is a $W$-structural $L'$ for $M$ such that $\varphi(F(L')) \subset L' + p^{n+1} M$.

Definition. Denote by $\mathcal{W}$-module in $L \otimes W$ is such that the coordinates of $f = \phi D$ form a $\mathcal{W}$-basis of $F(L)$. Then $\phi(f) = \epsilon + p^n \bar{h}$, where $\bar{h} \equiv 0 \mod JM$. Let $e' = \epsilon + p^n \bar{h}$ and let $L'$ be a $\mathcal{W}$-submodule in $M$ spanned by the coordinates of $e'$. Clearly, $L'$ is $\mathcal{W}$-structural. Prove that $F(L')$ is spanned by the coordinates of $e'$. Indeed, suppose $\phi$ and $\phi'$ have the coordinates $\epsilon^{(i)}$ and, resp., $\epsilon'^{(i)}$, $1 \leq i \leq s$. Then for all $i$, $e^{(i)} = e^{(i)} + p^n h^{(i)}$, where $h^{(i)} \in JM \subset (\text{Fil}^p S)M$. This means that a $\mathcal{W}$-linear combination of $e^{(i)}$ belongs to $F(M)$ if and only if the same linear combination of $e^{(i)}$ belongs to $F(M)$. This implies that $\phi' D$ spans $F(L')$ over $\mathcal{W}$ because $\epsilon D$ spans $F(L)$ over $\mathcal{W}$. Then $\phi(F(L')) \subset L' + p^{n+1}M$ because $\varphi(\bar{h}) \in \varphi(M)$ (use that $\varphi(J) \subset pS$) and

$$\varphi(e') = \varphi(\epsilon D + p^n \bar{h} D) = \epsilon + p^n \bar{h} + p^n \varphi(\bar{h}) \sigma(D) \equiv \epsilon' \mod p^{n+1} M$$

It remains to notice that applying above Lemmas 3.6 and 3.7 one after another we shall obtain a sequence of $\mathcal{W}$-structural modules $L_n$ such that for all $n \geq 0$, $L_n + p^{n+1}M = L_{n+1} + p^{n+1} M$, where $L_0 \otimes \mathcal{W} S = M$. Therefore, $L = \lim_{\to} L_n/p^n$ is $\mathcal{W}$-structural and $\varphi(L) \subset L$.

The proposition is completely proved.

3.5. The categories $\mathcal{L}^1$ and $\mathcal{L}^1'$

Definition. $\mathcal{W}$-module $L$ is $p$-strict if it is isomorphic to $\otimes_{1 \leq i \leq s} \mathcal{W}/p^{n_i}$, where $n_1, \ldots, n_s \in \mathbb{N}$.

In particular, if $L$ is $p$-strict and $pL = 0$ then $L$ is a free $\mathcal{W}_L$-module. The $p$-strict modules can be efficiently studied via devissage due to the following property.

Lemma 3.8. $L$ is $p$-strict if and only if $pL$ and $L/pL$ are $p$-strict.

Proof. Specify Breuil’s proof of a similar statement but for more complicated ring $S = \mathcal{W}_{dp}$ from [6].

Definition. Denote by $\mathcal{L}'$ the full subcategory in $\mathcal{L}$ consisting of the quadruples $L = (L, F(L), \varphi, N_S)$ such that

- $L$ is $p$-strict;
- $L \subset F(L)$, $F(L) \cap pL = \varphi(F(L)) \otimes_{\mathcal{W}} \mathcal{W}$;
- for any $l \in F(L)$, $vN_S(l) \in F(L_S)$ and $\varphi_S(vN_S(l)) = cN_S(\varphi(l))$, where $c = 1 + u^p/p$.

Definition. Denote by $\mathcal{L}'[1]$ the full subcategory in $\mathcal{L}'$, which consists of objects killed by $p$.

The category $\mathcal{L}'[1]$ is not very far from the category $\mathcal{L}^1$ introduced in Section 1. Indeed, suppose $L = (L, F(L), \varphi, N_S) \in \mathcal{L}'[1]$. Note that $N_S(L) \subset L_{S_1} := L \otimes_{\mathcal{W}_1} S_1 = L/u^p L \oplus (L \otimes \text{Fil}^p S_1)$. (Remind that $S_1 = S/pS = \mathcal{W}_1/u^p \mathcal{W}_1 \oplus \text{Fil}^p S_1$.) With this notation we have the following property.

Documenta Mathematica 18 (2013) 547–619
Proposition 3.9. There is a unique $N : L \rightarrow L/u^{2p}$ such that

a) for any $l \in L$, $N(l) \otimes 1 = cN_S(l)$ in $L_{S_1}$, where $c = 1 + u^p/p \in S^*$;

b) $(L, F(L), \varphi, N) \in \mathcal{L}^*$.

Proof. Let $N_1 := cN_S : L \rightarrow L_{S_1}$. Then for any $w \in W_l$ and $l \in L$, one has

\[ N_1(wl) = N(w)l + wN_1(l) \] (use that $N(c) = 0$ in $S_1$) and there is a commutative diagram (use that $\sigma(c) = 1$ in $S_1$)

\[
\begin{array}{ccc}
F(L) & \xrightarrow{\varphi} & L \\
\downarrow{uN_1} & & \downarrow{N_1} \\
F(L)_{S_1} & \xrightarrow{\varphi} & L_{S_1}
\end{array}
\]

Prove that $N_1(\varphi(F(L)) \subset L/u^pL$ and, therefore, $N_1(L) \subset L/u^pL$.

Indeed, $(uN_1)(F(L)) \subset uN_1(L) = F(L)_S \subset (uL/u^pL \oplus (uL)\operatorname{Fil}^pS_1)
\cap (F(L)/u^pL \oplus (uL)\operatorname{Fil}^pS_1) \subset F(L)/u^pL \oplus (uL)\operatorname{Fil}^pS_1$. This implies that $N_1(\varphi(F(L)) \subset \varphi_S(uN_1(F(L))) \subset L/u^pL$ because $\varphi_S(u\operatorname{Fil}^pS_1) = 0$. So, by Proposition 1.3 there is a unique $N : L \rightarrow L/u^{3p}$ such that $N \operatorname{mod} u^p = N_1$ and $(L, F(L), \varphi, N) \in \mathcal{L}^*$.

\[ \square \]

Corollary 3.10. With above notation the correspondence

\[ (L, F(L), \varphi, N_S) \mapsto (L, F(L), \varphi, N) \]

induces the equivalence of categories $\Pi : \mathcal{L}'[1] \rightarrow \mathcal{L}'^*$.

Proof. We must verify that our correspondence is surjective on objects and bijective on morphisms. The first holds because $N_S = c^{-1}N \operatorname{mod} u^p$ and the second — because a $W_l$-linear map $f$ commutes with $N$ iff it commutes with $N \operatorname{mod} u^p$ (use Proposition 1.2) iff $f \otimes_{W_l} S_1$ commutes with $N_S$.

\[ \square \]

Corollary 3.11. The category $\mathcal{L}'[1]$ is pre-abelian.

Proof. Corollary 3.10 and Proposition 1.3 imply that $\mathcal{L}'[1]$ is pre-abelian. This can be extended then to the whole category $\mathcal{L}'$ by Breuil’s method from [6] via above Lemma 3.8.

\[ \square \]
Varieties with Bad Reduction at 3 Only

According to Appendix A, we can use the concept of $p$-divisible group \( \{ L(n), i_n \}_{n \geq 0} \) in \( L^e \). In this case \( L(n) = (L_n, F(L_n), \varphi, N_S) \), where all \( L_n \) are free \( W/p^n \)-modules of the same rank equal to the height of this \( p \)-divisible group. We have obvious equivalence of the category \( L^e \) and the category of \( p \)-divisible groups of finite height in \( L^e \).

**Definition.** Denote by \( L^{f, e} \) the full subcategory in \( L^{e} \), which consists of strict subobjects of \( p \)-divisible groups in \( L^{e} \). By \( L^{f, e}[1] \) we denote the full subcategory in \( L^{f, e} \) consisting of all objects killed by \( p \).

It is easy to see that \( L^{f, e} \) contains all strict subquotients of the corresponding \( p \)-divisible groups. Contrary to the case of filtered modules coming from crystalline representations, the categories \( L^{f, e} \) and \( L^{e} \) do not coincide but they have the same simple objects.

Note that the functor \( \Pi \) from Corollary 3.10 identifies simple objects of the categories \( L^{f, e} \) and \( L^{e} \) and for any two objects \( L_1, L_2 \in L^{e}[1] \), we have a natural isomorphism \( \text{Ext}_{L^{e}[1]}(L_1, L_2) = \text{Ext}_{L^{e}}(\Pi(L_1), \Pi(L_2)) \). One can use the methods of Subsection 1.2 to extend the concepts of etale, connected, unipotent and multiplicative objects to the whole category \( L^{f, e} \). The starting point for this extension is the case of \( W(k) \)-modules, which is well-known from the classical Dieudonne theory [10]. Then we obtain the following standard properties:

- for any \( L \in L^{e} \), there are a unique maximal etale subobject \( (L^{e, t}, i^{e, t}) \) and a unique maximal connected quotient object \( (L^{e, c}, j^{e, c}) \) in \( L^{e} \) such that the sequence \( 0 \to L^{e, t} \xrightarrow{i^{e, t}} L \xrightarrow{j^{e, c}} L^{e, c} \to 0 \) is exact and the correspondences \( L \mapsto L^{e, t} \) and \( L \mapsto L^{e, c} \) are also objects of \( L^{f, e} \);

- for any \( L \in L^{e} \), there are a unique maximal unipotent subobject \( (L^{u, t}, i^{u, t}) \) and a unique maximal multiplicative quotient object \( (L^{m, c}, j^{m, c}) \) in \( L^{e} \) such that the sequence \( 0 \to L^{u, t} \xrightarrow{i^{u, t}} L \xrightarrow{j^{m, c}} L^{m, c} \to 0 \) is exact and the correspondences \( L \mapsto L^{u, t} \) and \( L \mapsto L^{m, c} \) are also objects of \( L^{f, e} \).

Denote by \( L^{e, t, f, e}, L^{e, u, t, f, e} \) and \( L^{m, t, f, e} \) the full subcategories in \( L^{e} \) consisting of, resp., etale, connected, unipotent and multiplicative objects. We have also the corresponding full subcategories \( L^{e, t, f, e}, L^{u, t, f, e} \) and \( L^{m, t, f, e} \) in \( L^{f, e} \).

The results of Subsection 1.5 and Appendix A imply that in the category \( L^{f, e} \):

- there is a unique etale \( p \)-divisible group \( L^\infty(0) := \{ L(n)(0), i_n \}_{n \geq 0} \) of height 1 such that \( L^{(1)}(0) = L(0) \);

- there is a unique multiplicative \( p \)-divisible group of height 1, \( L^\infty(1) := \{ L(n)(1), i_n \}_{n \geq 0} \) such that \( \Lambda^{(1)}(1) = \Lambda(1) \);

- for any \( p \)-divisible group \( L^\infty \) there are functorial exact sequences of \( p \)-divisible groups

\[
0 \to L^\infty, e \to L^\infty \to L^\infty, c \to 0
\]
Here $\mathcal{L}^{c,ft}$ and $\mathcal{L}^{\infty,\ast}$ are products of several copies of $\mathcal{L}^{\infty}(0)$ and, resp., $\mathcal{L}^{\infty}(1)$, and $\mathcal{L}^{\infty,c}$ and $\mathcal{L}^{\infty,\ast}$ are $p$-divisible groups in the categories $\mathcal{L}^{c,ft}$ and, resp., $\mathcal{L}^{u,ft}$.

4. Semistable modular representations with weights $[0, p)$

In this section we prove that all killed by $p$ subquotients of Galois invariant lattices of semistable $\mathbb{Q}_p[\Gamma_F]$-modules with Hodge-Tate weights $[0, p)$ can be obtained via the functor $\mathcal{V}^t$ from Section 2.

4.1. The functor $\mathcal{V}^t : \mathcal{L}^t \to \mathcal{M}_{\Gamma_F}^t$. For $n \geq 1$, introduce the objects $\mathcal{A}_{st,n} = (\hat{A}_{st,n}, F(\hat{A}_{st,n}), \varphi, N_S)$ of the category $\mathcal{L}_n^t$ with $\hat{A}_{st,n} = \hat{A}_{st}/p^n\hat{A}_{st}$, $F(\hat{A}_{st,n}) = F(\hat{A}_{st})/p^n F(\hat{A}_{st})$ and induced $\varphi$ and $N_S$. Let $\mathcal{A}_{st,\infty} = (\hat{A}_{st,\infty}, F(\hat{A}_{st,\infty}), \varphi, N_S)$ be the inductive limit of all $\mathcal{A}_{st,n}$. For $\mathcal{L} \in \mathcal{L}_n^t$, set $\mathcal{V}^t(\mathcal{L}) = \text{Hom}_\pi(\mathcal{L}, \mathcal{A}_{st,\infty})$ with the induced structure of $\Gamma_F$-module. This gives the functor $\mathcal{V}^t : \mathcal{L}^t \to \mathcal{M}_{\Gamma_F}^t$. We shall use the same notation for its restriction to the category $\mathcal{L}^{c,ft}$.

**Proposition 4.1.** Suppose $\mathcal{L} = (L, F(L), \varphi, N_S) \in \mathcal{L}^t$. Then $N_S|_{\varphi(F(L))}$ is nilpotent.

By deissage and Corollary 3.10 this is implied by the following statement for the objects of the category $\mathcal{L}_n^t$.

**Lemma 4.2.** If $\mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^t$ then $N^p(\varphi(F(L))) \subseteq u^p L$.

**Proof.** For any $l \in F(L), N(\varphi(l)) = \varphi(u^N(l))$. Use induction to prove that for $1 \leq m \leq p, N^m(\varphi(l)) \equiv \varphi(u^m N^m(l)) \mod u^p L$ and use then that $\varphi(u^p N^p(l)) \in \varphi(u F(L)) \subseteq u^p L$. \hfill $\square$

**Proposition 4.3.** For $n \geq 1$, $\oplus_{j \geq 0} A_{cr,n} \gamma_j(\log(1 + X))$ is the maximal $W(k)$-submodule of $\hat{A}_{st,n}$ where $N$ is nilpotent.

**Proof.** For any $j \geq 1$, one has $N(\gamma_j(\log(1 + X))) = \gamma_{j-1}(\log(1 + X))$ and $N$ is nilpotent on $\oplus_{j \geq 0} A_{cr,n} \gamma_j(\log(1 + X))$. Therefore, it will be sufficient to prove that

$$\text{Ker} \left(N^p|_{\hat{A}_{st,1}}\right) = \oplus_{0 \leq j < p} A_{cr,1} \gamma_j(\log(1 + X)).$$

Let $C = F_p\langle X \rangle$ be the divided power envelope of $F_p[X]$ with respect to the ideal $(X)$. Then $C = F_p[X_0, X_1, \ldots, X_n, \ldots]_{<p}$ is the ring of polynomials in $X_i := \gamma_i(X)$, where for all $i \geq 0, X_i^p = 0$.

Let $m_C$ be the maximal ideal of $C$ and $Y = \log(1 + X) \in C$. Then $Y \equiv X_0 - X_1 \mod m_C^2$, and for all $j \geq 0, \gamma_j(Y) \equiv X_j - X_{j+1} \mod m_C^2$. This implies that with $Y_j = \gamma_j(Y)$ for all $j \geq 0$,

$$C = F_p[X_0, Y_0, \ldots, Y_n, \ldots]_{<p} = F_p\langle Y \rangle[X]_{<p} = \oplus_{0 \leq i < p} F_p(Y) \gamma_i(X).$$

**Documenta Mathematica 18 (2013) 547–619**
Indeed, take $i$ and $N^\prime$. If $N^\prime$ is an $A_{cr,1}$-derivation, $N^\prime(X) = X + 1$ and $N^\prime(\gamma_j(Y)) = \gamma_j(Y)$, we obtain that for any $P = \sum_{i,j} \alpha_{ij}X^i\gamma_j(Y) \in F_p\{Y\}[X]_{<p}$ with $\alpha_{ij} \in F_p$,

$$N^p(P) = \sum_{i,j} \alpha_{ij}X^i\gamma_j(Y) + \sum_{i,j} (i+1)\alpha_{i+1,j}\gamma_j(Y)X^i + \sum_{i,j} \alpha_{i,j+p}X^i\gamma_j(Y).$$

If $P \in \text{Ker}N^p$ then for all involved indices $i, j$,

$$i\alpha_{ij} + (i+1)\alpha_{i+1,j} + \alpha_{i,j+p} = 0.$$

This implies that $\alpha_{ij} = 0$ if either $i \neq 0$ or $j \geq p$.

Indeed, take $i = p-1$. Then $-\alpha_{p-1,j} + \alpha_{p-1,j+p} = 0$. Because for $j \geq 0$, $\alpha_{p-1,j} = 0$ it implies that all $\alpha_{p-1,j} = 0$. Then proceed similarly with $i = p-2$ and so on. This proves that all $\alpha_{ij} = 0$ if $i \neq 0$. It remains to note that for $i = 0$, our relations give $\alpha_{0,j+p} = 0$ for all $j \geq p$.

As earlier, consider the category $\tilde{\mathcal{L}}$. Remind that its objects are the triples $(L, F(L), \varphi)$, where $L \supset F(L)$ are $W$-modules and $\varphi : F(L) \rightarrow L$ is a $A$-linear morphism. For any object $\mathcal{L} = (L, F(L), \varphi) \in \tilde{\mathcal{L}}$, agree to use the same notation $\mathcal{L}$ for the corresponding object $(L, F(L), \varphi) \in \tilde{\mathcal{L}}$.

For all $n \geq 0$, set $A_{cr,n} = (A_{cr}, F(A_{cr,n}), \varphi) \in \tilde{\mathcal{L}}$ with $A_{cr,n} = A_{cr}/p^nA_{cr}$, $F(A_{cr,n}) = F(A_{cr})/p^nF(A_{cr})$ and induced $\varphi$. Here the $W$-module structure on $A_{cr,n}$ is defined by the morphism of $W(k)$-algebras $W \rightarrow A_{cr,n}$ such that $u \mapsto [x_0]_{\mathcal{L}}$. Denote by $A_{cr,\infty}$ the inductive limit of all $A_{cr,n}$.

Suppose $\mathcal{L} \in \mathcal{L}^\prime$ and $f \in \text{Hom}_\mathcal{L}(\mathcal{L}, A_{cr,n})$. Then by Propositions 4.1 and 4.3,

$$f(\varphi(F(L))) \subset \oplus_{j \geq 0} A_{cr,n}\gamma_j(\log(1 + X)).$$

Consider the formal embedding of the algebra $A_{st,n}$ into the completion $\prod_{j \geq 0} A_{cr,n}\gamma_j(\log(1 + X))$ of $\oplus_{j \geq 0} A_{cr,n}\gamma_j(\log(1 + X))$ such that $X \mapsto \sum_{j \geq 1} \gamma_j(\log(1 + X))$. Then any element of $A_{st,n}$ can be uniquely written in the form $\sum_{j \geq 0} a_j \gamma_j(\log(1 + X))$, where all $a_j \in A_{cr,n}$. Note that the $W$-module structure on $A_{st,n}$ is given via the map

$$u \mapsto [x_0](1 + X) = [x_0] \sum_{j \geq 0} (-1)^j \gamma_j(\log(1 + X)).$$

For $j \geq 0$, introduce the $W(k)$-linear maps $f_j \in \text{Hom}(L, A_{cr,n})$ such that for any $l \in L$, one has $f(l) = \sum_{j \geq 0} f_j(l)\gamma_j(\log(1 + X))$. Then using methods from [6] obtain the following property.

**Proposition 4.4.** a) The correspondence $f \mapsto f_0$ induces isomorphism of abelian groups $\mathcal{V}^\prime(\mathcal{L}) = \text{Hom}_\mathcal{L}(\mathcal{L}, A_{cr,n})$;
b) for any $j \geq 0$ and $l \in L$, $f_j(l) = f_0(N^j(l))$.

**Corollary 4.5.** The functor $\mathcal{V}^\prime$ is exact.
Proof. Let $L_1'$ be the full subcategory of $L_1$, consisting of the triples $(L, F(L), \varphi)$ coming from all $L = (L, F(L), \varphi, N) \in L_1'$. By Proposition 4.4 it will be sufficient to prove that the functor $\mathcal{V}_0^0 : L_1' \to (Ab)$, such that $\mathcal{V}_0^0(L) = \text{Hom}_{\mathcal{C}_0}(L, \mathcal{A}_{cr,\infty})$, is exact. The verification can be done by devisage along the lines of paper [13].

Remark. One can simplify the verification of above corollary by replacing $\mathcal{A}_{cr,1}$ by the corresponding object $\tilde{\mathcal{A}}_{cr,1}$ related to the module $\tilde{A}_{cr,1} = (R/x_0^pT_1, \ldots) \subset \mathcal{C}_0$. Let $\tilde{\mathcal{A}}_{cr,1}$ be related to the module $\tilde{A}_{cr,1} = (R/x_0^pT_1, \ldots) \subset \mathcal{C}_0$. Then in notation of Corollary 3.2, $T_{st}(L) = \lim_{\to_n}^{\text{Hom}}(L_1^0(L))$.

4.2. The functor $\mathcal{V}[1]^*$. Note the following case of Proposition 4.4.

Proposition 4.7. Suppose $L = (L, F(L), \varphi, N) \in L_1'[1]$. Then there is an isomorphism of abelian groups $\mathcal{V}^1(L) \cong \text{Hom}_{\mathcal{C}_0}(L, \mathcal{A}_{cr,1})$. In addition, $\Gamma_F$ acts on $\mathcal{V}^1(L)$ via its natural action on $\mathcal{A}_{st,1}$ and the identification $\mathcal{V}^1(L) \cong \text{Hom}_{\mathcal{C}_0}(L, \mathcal{A}_{cr,1})$ such that if $f_0 \in \text{Hom}_{\mathcal{C}_0}(L, \mathcal{A}_{cr,1})$ then for any $l \in L$,

$$
\iota_L(f_0)(l) = \sum_{j \geq 0} f_0(N^j(l))\gamma_j(\log(1 + X))
$$

Introduce the functor $\mathcal{V}[1]^* := \mathcal{V}[1]^{\text{C}_0} \circ \Pi^{-1} : \mathcal{L}^* \to \mathcal{M}_{\Gamma_F}$, where $\Pi : \mathcal{L}'[1] \to \mathcal{L}^*$ is the equivalence of categories from Corollary 3.10.

Proposition 4.8. On the subcategory of unipotent objects $\mathcal{L}^u$ of $\mathcal{L}^*$ the functors $\mathcal{V}[1]^*$ and $\mathcal{V}^*$ coincide.

Proof. The definition of $\mathcal{A}_{cr}$ implies that $\mathcal{A}_{cr,1} = (R/x_0^pT_1, T_2, \ldots) \subset \mathcal{C}_0$, where for all indices $i \geq 1$, $T_i$ comes from $\gamma_i^p([x_0^p] + p)$ and $T_i^p = 0$. Set $F(\mathcal{A}_{cr,1}) = \text{Fil}^{-1} \mathcal{A}_{cr,1} = (x_0^pR/x_0^pR) \oplus (R/x_0^pT_1)$, where the ideal $T_1$ is generated by all $T_i$. Then the corresponding map $\varphi : F(\mathcal{A}_{cr,1}) \to \mathcal{A}_{cr,1}$ is uniquely determined by the conditions $\varphi(x_0^p) = 1 - T_1$, $\varphi(T_1) = 1$ and $\varphi(T_i) = 0$ if $i \geq 2$. In particular, $\varphi(\mathcal{A}_{cr,1}) \subset (R/x_0^pT_1) \oplus (R/x_0^p)$.

Let $\tilde{\mathcal{A}}_{cr,1} = \mathcal{A}_{cr,1}/J_1$ with the induced structure of filtered $\varphi$-module $\tilde{\mathcal{A}}_{cr,1}$, where the ideal $J_1$ of $\mathcal{A}_{cr,1}$ is generated by the elements $T_1x_0^p$ and $T_i$ with $i \geq 2$. Then the projection $\mathcal{A}_{cr,1} \to \tilde{\mathcal{A}}_{cr,1}$ induces for any object $L = (L, F(L), \varphi, N)$ of the category $\mathcal{L}^u$, the identification (use that $\varphi|_J = 0$)

$$
\text{Hom}_{\mathcal{C}_0}(L, \mathcal{A}_{cr,1}) = \text{Hom}_{\mathcal{C}_0}(L, \tilde{\mathcal{A}}_{cr,1}).
$$

Introduce $a_0, a_{-1} \in \text{Hom}(L, R/x_0^p)$ such that for any $m \in L$, $f_0(m) = a_{-1}(m)T_1 + a_0(m)$. Note that $a_0$ and $a_{-1}$ are $\mathcal{W}_1$-linear, where the multiplication by $u$ on $L$ corresponds to the multiplication by $x_0$ in $R/x_0^p$.

Then for any $m \in F(L)$, the requirement $f_0(\varphi(m)) = \varphi(f_0(m))$ is equivalent to the conditions
\begin{align*}
a_0(\varphi(m)) &= a_{-1}(m)p + \frac{a_0(m)p}{x_0^{p(p-1)}} \\
a_{-1}(\varphi(m)) &= -\frac{a_0(m)p}{x_0^{p(p-1)}}
\end{align*}

Note that these conditions depend only on \( m = m \mod u^pL \).

Consider the operator \( V : L \to L \) from Subsection 1.5. Clearly, \( V(u^pL) \subset uF(L) \) and for \( \bar{L} := L/u^pL \), we obtain the induced operator \( V : \bar{L} \to \bar{L} \) (use that \( F(L)/uF(L) \subset L/u^pL \)).

For any \( m \in L \), relations (4.1) can be rewritten as follows:
\begin{align*}
a_0(m) &= \frac{a_0(\bar{V}m)p}{x_0^{p(p-1)}} + a_{-1}(\bar{V}m)p \\
a_{-1}(m) &= -\frac{a_0(\bar{V}m)p}{x_0^{p(p-1)}}
\end{align*}

Therefore, if \( \mathcal{L} \) is unipotent then for any \( m \in \bar{L} \),
\begin{align*}
a_{-1}(m) &= -a_0(m) + a_{-1}(\bar{V}m)p = -a_0(m) + a_{-1}(V^2m)p = \cdots = -a_0(m).
\end{align*}

This implies that for any \( m \in F(\bar{L}) \), \( a_0(\varphi(m)) = a_0(m)p/x_0^{p(p-1)} \). In other words, we have a natural identification
\[
\Hom_{\mathcal{L}}(\mathcal{L}, \tilde{\mathcal{R}}^u) = \Hom_{\mathcal{L}}(\mathcal{L}, \tilde{\mathcal{A}}_{cr,1})
\]

coming from the map of filtered \( \varphi \)-modules \( \tilde{\mathcal{R}}^u \to \tilde{\mathcal{A}}_{cr,1} \) given by the \( R \)-linear map \( R/x_0^{p} \to \tilde{\mathcal{A}}_{cr,1} = (R/x_0^p)T_1 \oplus (R/x_0^p) \) such that for any \( r \in R/x_0^p \),
\[
r \mapsto (-\bar{r}T_1, r).
\]
(For the definition of \( \tilde{\mathcal{R}} \in \mathcal{L}^{u*} \), cf. Subsection 2.2.)

This implies that for all unipotent \( \mathcal{L} \in \mathcal{L}^{u*} \), there is a natural identification of \( \Gamma_F \)-modules \( V[1]^*\mathcal{L} = \mathcal{V}^*\mathcal{L} \). Indeed, the above embedding \( R/x_0^p \to \tilde{\mathcal{A}}_{cr,1} \) can be extended to the embedding of \( R_{st}/x_0^pR_{st} \) to
\[
\tilde{\mathcal{A}}_{st,1} = \prod_{j \geq 0} \tilde{\mathcal{A}}_{cr,1} \gamma_j(\log(1 + X)),
\]

which induces the above identification. \( \square \)

4.3. Splittings \( \Theta \) and \( \tilde{\Theta} \). Suppose \( \mathcal{L} = (L, F(L), \varphi, N) \in \mathcal{L}^{*} \). Then there is a standard short exact sequence
\[
(4.2) \quad 0 \to \mathcal{L}_u \overset{i}{\to} \mathcal{L} \overset{j}{\to} \mathcal{L}^m \to 0,
\]
where \( (\mathcal{L}_u, i) \) is the maximal unipotent subobject and \( (\mathcal{L}^m, j) \) is the maximal multiplicative quotient of \( \mathcal{L} \).

If \( \mathcal{L}^m = (L^m, F(L^m), \varphi, N) \) then \( F(L^m) = L^m \otimes_{\mathbb{F}_p} \mathcal{W}_1 \), where \( L_0 = \{ l \in L^m \mid \varphi(l) = l \} \). Suppose \( S : L^m \to F(L) \subset L \) is a \( \mathcal{W}_1 \)-linear section. Then for any \( l_0 \in L_0 \), \( S(l_0) = \varphi(S(l_0)) + g(l_0) \), where \( g \in \Hom(L_0, L^m) \). If \( S' : L^m \to \mathcal{X} \), then \( S'(l_0) = \varphi(S'(l_0)) + g'(l_0) \), where \( g' \in \Hom(L_0, L^m) \).
\[ F(L) \] is another \( W \)-linear section then for any \( l_0 \in L_0 \), \( S'(l_0) = \varphi(S(l_0)) + g'(l_0) \). Here \( g' \in \text{Hom}(L_0, L^u) \) is such that for some \( h \in \text{Hom}(L_0, L^u) \), one has
\[
(g' - g)(l_0) = h(l_0) - \varphi(h(l_0)).
\]

**Proposition 4.9.** a) There is a section \( S \) such that \( g(L_0) \subset uL^u \).
b) If \( g(L_0), g'(L_0) \subset uL^u \) then \( h(L_0) \subset uF(L^u) \).

**Proof.** a) It will be sufficient to prove that for any \( l \in L^u \), there is an \( h \in F(L^u) \) such that \( l \equiv h - \varphi(h) \mod uL^u \).

Suppose \( n_0 \geq 1 \) is such that \( V^{n_0}(L^u) \subset uF(L^u) \). Then for all \( n \geq n_0 \), \( V^n(L^u) \subset uF(L^u) \). Let \( h = -(Vl + V^2l + \cdots + V^{n_0+l}l) \). By the definition of the operator \( V \) for all \( 1 \leq i \leq n_0 + 1 \), \( V^i l \in F(L^u) \) and \( \varphi(V^i l) \equiv V^{i-1}l \mod uL^u \). Therefore, \( h \in F(L^u) \) and \( \varphi(h) = -(l + Vl + \cdots + V^{n_0+l}l) \equiv -l - h \mod uL^u \).

b) We must prove that if \( h \in F(L^u) \) and \( h - \varphi(h) \in uL^u \) then \( h \in uF(L^u) \).

Indeed, we have \( V(h) - h \in V(uL^u) \subset uF(L^u) \) and for all \( n \geq 1 \), \( V^n(h) \equiv h \mod uF(L^u) \) implies that \( h \in uL^u \). Therefore, \( \varphi(h) \in uL^u \) and \( h \in uF(L^u) \).

\[ \square \]

**Proposition 4.10.** With above notation the short exact sequence
\[ 0 \longrightarrow V[1]^*(L^u) \longrightarrow V[1]^*(L) \longrightarrow V[1]^*(L^c) \longrightarrow 0 \]

obtained from (4.2) by applying \( V[1]^* \), has a canonical functorial splittings \( \Theta : V[1]^*(L^u) \longrightarrow V[1]^*(L) \) and \( \tilde{\Theta} : V[1]^*(L) \longrightarrow V[1]^*(L^c) \) in the category \( \mathcal{M}_F^w \).

**Proof.** It will be sufficient to prove the existence of a functorial splitting
\[ \Theta : \text{Hom}_F(L^u, \tilde{A}_{cr,1}) \longrightarrow \text{Hom}_F(L, \tilde{A}_{cr,1}) \]
of the epimorphism \( \text{Hom}_F(L^u, \tilde{A}_{cr,1}) \rightarrow \text{Hom}_F(L, \tilde{A}_{cr,1}) \), obtained from exact sequence (4.2).

Suppose \( f_0 = (a_{-1}, a_0) : L^u \longrightarrow (R/x_0^p)T_1 \oplus (R/x_0^p) \) belongs to \( \text{Hom}_F(L^u, \tilde{A}_{cr,1}) \). Here \( a_{-1}, a_0 \in \text{Hom}_{\mathbb{W}_L}(L^u, R/x_0^p) \) and for any \( l \in L^u \), \( a_{-1}(l) = -a_0(l) \), cf. Subsection 4.2.

Let \( S : L^m \rightarrow L \) be a \( W \)-linear section such that for any \( l \in L_0 \), \( S(l_0) = \varphi(S(l_0)) + g(l_0) \), where \( g \in \text{Hom}(L_0, uL^u) \).

Extend \( f_0 \) to \( \Theta(f_0) = (a_{-1}, a_0) : L \longrightarrow (R/x_0^p)T_1 \oplus (R/x_0^p) \) by setting \( a_{-1}(S(l_0)) = -a_0(S(l_0)) = X \), where \( X \) is a unique element of \( R/x_0^p \) such that \( X = X^p/x_0^{p(p-1)} = a_0(g(l_0)) \). One can prove that \( \Theta(f_0) \in \text{Hom}_F(L, \tilde{A}_{cr,1}) \) by verifying relations (4.1) with \( m = S(l_0) \).

\[ \square \]

4.4. A modification of Breuil’s functor. Remind that Breuil’s functor \( V^t : L^t \longrightarrow \mathcal{M}_F^w \) attaches to any \( L \in L^t \), the \( \Gamma_F \)-module \( V(L) = \text{Hom}_F(L, \tilde{A}_{cr,\infty}) \).

**Proposition 4.11.** The functor \( V^t \) is fully faithful on the subcategory of unipotent objects \( L^{t,u} \).
Proposition 4.10 implies that $\mathcal{V}^t$ is very far from to be fully faithful on the whole $\mathcal{L}^{ft}$: if $\mathcal{L} \in \mathcal{L}^{ft}[1]$ and $0 \rightarrow \mathcal{L}^u \rightarrow \mathcal{L} \rightarrow \mathcal{L}^m \rightarrow 0$ is the standard exact sequence then the corresponding sequence of $\Gamma_{\mathcal{F}}$-modules admits a functorial splitting.

Introduce a modification $\widetilde{\mathcal{V}}^{ft}: \mathcal{L}^{ft} \rightarrow \text{M}_{\mathcal{F}}$ of Breuil’s functor. Suppose $\mathcal{L} \in \mathcal{L}^{ft}$. From the definition of the category $\mathcal{L}^{ft}$ in Subsection 3 it follows the existence of $\mathcal{L}' \in \mathcal{L}^{ft}$ such that $p\mathcal{L}' = \mathcal{L}$. More precisely, there are a strict monomorphism $i_{\mathcal{L}'}: \mathcal{L} \rightarrow \mathcal{L}'$ and a strict epimorphism $j_{\mathcal{L}'}: \mathcal{L}' \rightarrow \mathcal{L}$ such that $p \circ i_{\mathcal{L}'} = i_{\mathcal{L}'} \circ j_{\mathcal{L}'}$. (Note that $j_{\mathcal{L}'} \circ i_{\mathcal{L}'} = p \circ i_{\mathcal{L}'}$.)

Consider the following short exact sequences

$$0 \rightarrow \mathcal{L} \xrightarrow{i_{\mathcal{L}'} \circ} \mathcal{L}' \xrightarrow{C_p} \mathcal{L}' \rightarrow 0$$

and the corresponding sequence of $\Gamma_{\mathcal{F}}$-modules and their morphisms

$$\mathcal{V}^t(\mathcal{L}^u) \xrightarrow{\Theta} \mathcal{V}^t(\mathcal{L}') \xrightarrow{\mathcal{V}^t(C_p)} \mathcal{V}^t(\mathcal{L}') \xrightarrow{\mathcal{V}^t(K_{p})} \mathcal{V}^t(\mathcal{L}_p^m) \xrightarrow{\Theta} \mathcal{V}^t(\mathcal{L}_p^m)$$

As earlier, for any $\mathcal{L} \in \mathcal{L}^{ft}$, $\mathcal{L}^u$ is the maximal unipotent subobject and $\mathcal{L}^m$ is the maximal multiplicative quotient object for $\mathcal{L}$.

**Lemma 4.12.** $\text{Ker} (\widetilde{\Theta} \circ \mathcal{V}^t(K_p)) \supset \text{Im} (\mathcal{V}^t(C_p) \circ \Theta)$.

**Proof.** The section $\Theta$ depends functorially on objects of the category $\mathcal{L}^{ft}[1] \supset \mathcal{L}^{ft}[1]$. Therefore, we have the following commutative diagram

$$\begin{array}{ccc}
\mathcal{V}^t(\mathcal{L}^u) & \xrightarrow{\mathcal{V}^t(C_p \circ K_p)} & \mathcal{V}^t(\mathcal{L}_p^m) \\
\widetilde{\Theta} \circ \mathcal{V}^t(K_p) \circ \mathcal{V}^t(C_p) & \Theta & \mathcal{V}^t(C_p \circ K_p)
\end{array}$$

and $\widetilde{\Theta} \circ \mathcal{V}^t(K_p) \circ \mathcal{V}^t(C_p) \circ \Theta = (\widetilde{\Theta} \circ \Theta) \circ \mathcal{V}^t(C_p \circ K_p) = 0$. □

**Definition.** Set $\mathcal{V}_{\mathcal{L},\mathcal{L}'}(\mathcal{L}) = \text{Ker} (\widetilde{\Theta} \circ \mathcal{V}^t(K_p))/\text{Im} (\mathcal{V}^t(C_p) \circ \Theta)$.

**Proposition 4.13.** With above notation one has:

a) $\mathcal{V}_{\mathcal{L},\mathcal{L}'}(\mathcal{L}) = \text{Coker} \mathcal{V}^t(C_p) = \mathcal{V}^t(\mathcal{L})$ if $\mathcal{L} \in \mathcal{L}^{u,ft}$;

b) $\mathcal{V}_{\mathcal{L},\mathcal{L}'}(\mathcal{L}) = \text{Ker} \mathcal{V}^t(K_p) = \mathcal{V}^t(\mathcal{L})$ if $\mathcal{L} \in \mathcal{L}^{m,ft}$;

c) for any $\mathcal{L} \in \mathcal{L}^{ft}$, we have the induced exact sequence of $\Gamma_{\mathcal{F}}$-modules

$$0 \rightarrow \mathcal{V}^t(\mathcal{L}_p^m) \rightarrow \mathcal{V}^t(\mathcal{L}_p^m) \rightarrow \mathcal{V}^t(\mathcal{L}_p^u) \rightarrow 0.$$ This sequence depends functorially on the pair $(\mathcal{L}, \mathcal{L}')$. 

---

*Documenta Mathematica 18 (2013) 547–619*
The correspondence $L \rightarrow n$ is sufficient to verify that for maps on $V$ from functoriality and diagram chasing implies that it induces the identity map $p$. This gives a functorial sequence

$$0 \rightarrow V_{\mathcal{L}}^n(L^m) \rightarrow V_{\mathcal{L}}^n(L) \rightarrow V_{\mathcal{L}}^n(L^n) \rightarrow 0.$$ 

Then standard diagram chasing proves that this sequence is exact.

**Proposition 4.14.** Suppose for a given $L \in \mathcal{L}^{ft}$, the objects $L', L'' \in \mathcal{L}^{ft}$ are such that $pL' = pL'' = L$. Then there is a natural isomorphism $f(L', L'')$ of $\Gamma_F$-modules such that the following diagram is commutative

$$
\begin{array}{ccc}
0 & \rightarrow & V^1(L^m) \\
\downarrow{id} & & \downarrow{id} \\
0 & \rightarrow & V^1(L') \\
\end{array}
\begin{array}{ccc}
V^1(L^m) & \rightarrow & V^1(L'') \\
\downarrow{f(L', L'')} & & \downarrow{\text{id}} \\
V^1(L') & \rightarrow & V^1(L'') \\
\end{array}
\begin{array}{ccc}
0 & \rightarrow & V^1(L^m) \\
\end{array}
\begin{array}{ccc}
0 & \rightarrow & V^1(L') \\
\end{array}
\begin{array}{ccc}
0 & \rightarrow & V^1(L'') \\
\end{array}
(\text{The lines of this diagram are given by Prop 4.13)}

**Proof.** By replacing $L''$ by $\prod_{\mathcal{L}} L''$ with respect to strict epimorphisms $j_{\mathcal{L}}$ and $j_{\mathcal{L}', \mathcal{L}''}$, we can assume that there is a map $f : L'' \rightarrow L'$ which induces the identity map $pL'' = L \rightarrow pL' = L$. Then the existence of $f(L', L'')$ follows from functoriality and diagram chasing implies that it induces the identity maps on $V^1(L^n)$ and $V^1(L^m)$.

**Definition.** For $L, L' \in \mathcal{L}^{ft}$ such that $pL' = L$, set $\hat{V}^{ft}(L) = V_{\mathcal{L}}^n(L)$.

The correspondence $L \rightarrow \hat{V}^{ft}(L)$ induces the additive exact functor $\hat{V}^{ft} : \mathcal{L}^{ft} \rightarrow \text{MF}_F$.

4.5. $\varphi$-filtered module $\tilde{A}_{cr, 2} \subseteq \tilde{B}_0$. Let $\xi = [x_0] + p \in W(R) \subset A_{cr}$, and for $n \in \mathbb{N}$, $\gamma_n(\xi) = \xi^n/n!$

**Lemma 4.15.** If $n \geq 2p$ then $\varphi(\gamma_n(\xi)) \in p^2A_{cr}$.

**Proof.** We have $\varphi(\gamma_n(\xi)) = (p^{n-p+1}/n!)([x_0]^p/p + 1)^n$. Therefore, it will be sufficient to verify that for $n \geq 2p$, $v_p(n!) + p + 1 \leq n$. Using the estimate $v_p(n!) < n/(p - 1)$ we obtain that the required inequality holds for $p \geq 5$ if $n \geq p + 3$ and for $p = 3$ if $n \geq 8$. It remains to check that our inequality holds for $p = 3$ and $n \in \{6, 7\}$.

Let $J_2$ be the closed ideal in $A_{cr}$ generated by $[x_0]^p\xi^n/p$ and all $\xi^n/n!$ with $n \geq 2p$. Then $J_2 \subset F(A_{cr})$ and $\varphi(J_2) \subset p^2A_{cr}$. Introduce $\tilde{A}_{cr, 2} = A_{cr}/(J_2 + p^2A_{cr})$ and consider the corresponding induced filtered $\varphi$-module $\tilde{A}_{cr, 2} = (\tilde{A}_{cr, 2}, F(\tilde{A}_{cr, 2}), \varphi) \subseteq \tilde{B}_0$. Clearly, for any $L \in \mathcal{L}$, the natural projection $A_{cr, 2} \rightarrow \tilde{A}_{cr, 2}$ induces the identification $\text{Hom}_{\mathcal{L}}(L, A_{cr, 2}) = \text{Hom}_{\mathcal{L}}(L, \tilde{A}_{cr, 2})$.

Consider the structure of $\tilde{A}_{cr, 2}$ more closely.
Let $T_1 = \xi^p/p$. With obvious notation the elements of $\tilde{A}_{cr,2}$ can be written uniquely modulo the subgroup $[x_0^pR]T_1 + [x_0^pR] + p[x_0^pR] + p^2W(R)$ in the form $[r_1]T_1 + [r_0] + p[r_1]$, where $r_1, r_0, r_1 \in R$. In formally, we shall use that $r_1, r_0 \in R/x_0^p$ and $r_0 \in R/x_0^2$. The $W(R)$-module structure on $\tilde{A}_{cr,2}$ is induced by usual operations on Teichmuller’s representatives and the relation $pT_1 \equiv [x_0]^p \mod p^2W(R)$. (Use that $T_1 \equiv [x_0]^p/p + p[x_0]^{p-1} \mod p^2W(R)$.)

The $S$-module structure on $\tilde{A}_{cr,2}$ is induced by the $W(k)$-algebra morphism $S \rightarrow W(R)$ such that $u \mapsto [x_0]$. Then $F(\tilde{A}_{cr,2})$ is generated over $W(R)$ by the images of $T_1$ and $\xi^{p-1}$. Note that $\xi^{p-1} \equiv [x_0]^{p-1} - p[x_0]^{p-2} \mod p^2W(R)$. The map $\varphi : F(\tilde{A}_{cr,2}) \rightarrow \tilde{A}_{cr,2}$ is uniquely determined by the knowledge of $\varphi(T_1)$ and $\varphi(\xi^{p-1})$. Note that

$$
\varphi(T_1) = \left(\frac{1 + [x_0]^p}{p}\right)^p \equiv 1 + [x_0]^p \mod (J + p^2A_{cr,2} + p[m_R])
$$

$$
\varphi(\xi^{p-1}) = \left(\frac{1 + [x_0]^p}{p}\right)^{p-1} \equiv 1 - T_1 \mod (J + p^2A_{cr,2} + p[m_R])
$$

Suppose $L \in \mathcal{L}^{f^1[1]}$ and $L' \in \mathcal{L}^{f^2}$ is such that $pL' = L$. Consider short exact sequences (4.3) and (4.4). Then the points $f \in \mathcal{V}^t(pL')$ and $\mathcal{V}^t(C_p)(f) \in \mathcal{V}^t(L')$ are related via the commutative diagram

\[
\begin{array}{ccc}
\mathcal{L}' & \xrightarrow{\mathcal{V}^t(C_p)(f)} & \tilde{A}_{cr,2} \\
\downarrow{\mathcal{V}^t(C_p)(f)} & & \downarrow{\mathcal{V}^t(C_p)(f)} \\
pL' & \xrightarrow{f} & \tilde{A}_{cr,1}
\end{array}
\]

where the right vertical arrow is induced by the correspondence $[r_1]T_1 + [r_0] + p[r_1] \mapsto [r_1]T_1 + [r_0] \mod x_0^p]$. Similarly, the points $g \in \mathcal{V}^t(L')$ and $\mathcal{V}^t(K_p)(g) \in \mathcal{V}^t(L'_p)$ are related via the commutative diagram

\[
\begin{array}{ccc}
\mathcal{L}' & \xrightarrow{g} & \tilde{A}_{cr,2} \\
\downarrow{K_p} & & \downarrow{K_p} \\
L'_p & \xrightarrow{\mathcal{V}^t(K_p)(g)} & \tilde{A}_{cr,1}
\end{array}
\]

where the right vertical arrow is induced by the correspondence $[r_1]T_1 + [r_0] \mapsto [r_1]x_0^p] + p[r_0]$. 

*Documenta Mathematica* 18 (2013) 547–619
4.6. Filtered $\varphi$-modules $A_{cr,1}^0$ and $A_{cr,2}^0$. Let $A_{cr,2}^0$ be the $W(R)$-submodule of $\tilde{A}_{cr,2}$ consisting of elements $[r_{-1}]T_1 + [r_0] + p[r_1]$ such that $r_{-1} = -r_0 \mod x_0^p$. Then $F(A_{cr,2}^0) = F(\tilde{A}_{cr,2}) \cap A_{cr,2}^0$ is generated over $W(R)$ by $[x_0^{p-1}]T_1 + x_0^{p-1}$ and the congruence
\[
\varphi([x_0^{p-1}]T_1 + x_0^{p-1}) \equiv -T_1 + 1 \mod (J_2 + p^2 A_{cr,2} + p|m_R])
\]
implies that $\varphi(F(A_{cr,2}^0)) \subset A_{cr,2}^0$ and $A_{cr,2}^0 = (A_{cr,2}^0, F(A_{cr,2}^0), \varphi) \in \tilde{L}_0$.

Note that $pA_{cr,2}^0 = (pA_{cr,2}^0, pF(A_{cr,2}^0), \varphi) \in \tilde{L}_0$. Then in notation from Subsection 4.4, one has:

- $\text{Im } \Theta = \text{Hom}_{\tilde{L}_0}(p\mathcal{L}', pA_{cr,2}^0)$;
- $\text{Ker } \Theta = \text{Hom}_{\tilde{L}_0}((\mathcal{L}', pA_{cr,2}^0)$;
- $\text{Ker } (\Theta \circ \mathcal{V}^t(K_p)) = \text{Hom}_{\tilde{L}_0}((\mathcal{L}', A_{cr,2}^0)$.

Therefore, $\tilde{\mathcal{V}}^t(\mathcal{L}) = \mathcal{V}^t(\mathcal{L}) = \text{Hom}_{\tilde{L}_0}((\mathcal{L}', A_{cr,2}^0/pA_{cr,2}^0)$.

4.7. The functor $\tilde{\mathcal{V}}^t$. Let $\mathcal{L} \in L_{\mathcal{L}}^t$ and let $i^t : \mathcal{L}^t \to \mathcal{L}$ be the maximal etale subobject of $\mathcal{L}$.

DEFINITION. $\tilde{\mathcal{V}}^t : L_{\mathcal{L}}^t \to \text{CMF}_R$ is the functor induced by the correspondence $\mathcal{L} \mapsto \tilde{\mathcal{V}}^t(\mathcal{L}) = (\tilde{\mathcal{V}}^t(\mathcal{L}), \tilde{\mathcal{V}}^t(\mathcal{L}^t), \tilde{\mathcal{V}}^t(i^t))$.

The functor $\tilde{\mathcal{V}}^t$ is not very far from Breuil’s functor $\mathcal{V}^t$ but it satisfies the following important property.

PROPOSITION 4.16. The functor $\tilde{\mathcal{V}}^t$ is fully faithful.

Proof. By standard devissage it will be sufficient to verify this property for the restriction $\tilde{\mathcal{V}}^t|_{\mathcal{L}^t[X]}$. Due to Proposition 2.13 it will be sufficient to verify that the functor $\tilde{\mathcal{V}}^t|_{\mathcal{L}^t[X]} \circ \Pi^{-1}$ coincides with the functor $\mathcal{V}^t$ from Subsection 2.2. This can be proved similarly to the proof of the corresponding fact for unipotent objects in Subsection 4.2 as follows.

Let
\[
A_{st,2}^0 = \prod_{j \geq 0} A_{cr,2}^0 \gamma_j(\log(1 + X)) \subset \tilde{A}_{st,2} = \prod_{j \geq 0} \tilde{A}_{cr,2} \gamma_j(\log(1 + X))
\]
with induced structures of the objects $A_{st,2}^0$ and $\tilde{A}_{st,2}$ of the category $\tilde{L}$. Then from Subsection 4.6 it follows that
\[
\mathcal{V}^t(\mathcal{L}) = \text{Hom}_{\tilde{L}_0}(\mathcal{L}, A_{st,2}^0/p A_{st,2}^0).
\]
One can see easily that the correspondence
\[
[r_0 \mod x_0^p]T_1 + [r_0] + p[r_1] \mapsto (r_0 + x_0^p r_1) \mod x_0^p m_R
\]
induces the morphism $A_{cr,2}^0/pA_{cr,2}^0 \to R^0$ in the category $\tilde{\mathcal{L}}_0$. This morphism induces a unique identification of the abelian groups $V^t(L)$ and $\text{Hom}(L, R^0) = V^t(L)$. Now going to a suitable factor of the object $A_{st,2}^0/pA_{st,2}^0$ we obtain that this identification is compatible with the $\Gamma_F$-actions on both abelian groups. □

Now we can describe all Galois invariant lattices of semi-stable $\mathbb{Q}_p[\Gamma_F]$-modules with weights from $[0, p)$.

**Corollary 4.17.** Suppose $V$ is a semi-stable representation of $\Gamma_F$ with weights from $[0, p)$, $\dim_{\mathbb{Q}_p} V = s$ and $T$ is a $\Gamma_F$-invariant lattice in $V$. Then there is a $p$-divisible group $\{L^{(n)}, i_n\}_{n \geq 0}$ of height $s$ in $\mathcal{L}_f$ such that $\lim_{\leftarrow} \tilde{C}V^{(n)}(L^{(n)}) = (T, T^{et}, i^{et}) \in \text{CM}_{\Gamma_F}$.

5. Proof of Theorem 0.1.

As earlier, $p$ is a fixed prime number, $p \neq 2$. Starting Subsection 5.2 we assume $p = 3$.

5.1. For all prime numbers $l$, choose embeddings of algebraic closures $\overline{\mathbb{Q}} \subset \overline{\mathbb{Q}}_l$ and use them to identify the inertia groups $I_l = \text{Gal}(\overline{\mathbb{Q}}_l/\mathbb{Q}_l_{ur})$, where $\mathbb{Q}_l_{ur}$ is the maximal unramified extension of $\mathbb{Q}_l$, with the appropriate subgroups in $\Gamma_\mathbb{Q} = \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$.

Introduce the category $\mathcal{M}_\Gamma^{\mathbb{Q}}$. Its objects are the pairs $H_\mathbb{Q} = (H, \tilde{H}_{st})$, where $H$ is a finite $\mathbb{Z}_p[\Gamma_\mathbb{Q}]$-module unramified outside $p$ and $\tilde{H}_{st} = (H_{st}, H^0_{st}, i) \in \text{CM}_{\Gamma_F}$, where $H|_{I_p} = H_{st}$, $F = W(\overline{\mathbb{F}}_p)[1/p]$ and $\text{CM}_{\Gamma_F}$ is the image of the functor $\tilde{C}V^{f}$ from Subsection 4.7. The morphisms in $\mathcal{M}_\Gamma^{\mathbb{Q}}$ are compatible morphisms of Galois modules. Clearly, the category $\mathcal{M}_\Gamma^{\mathbb{Q}}$ is special pre-abelian, cf. Appendix A.

Let $\mathcal{M}_\Gamma^{\mathbb{Q}}[1]$ be the full subcategory of killed by $p$ objects in $\mathcal{M}_\Gamma^{\mathbb{Q}}$. Denote by $\mathcal{K}(p)$ an algebraic extension of $\mathbb{Q}$ such that for any $H_\mathbb{Q} = (H, \tilde{H}_{st}) \in \mathcal{M}_\Gamma^{\mathbb{Q}}[1]$, $\Gamma_{\mathcal{K}(p)} = \text{Gal}(\overline{\mathbb{Q}}/\mathcal{K}(p))$ acts trivially on $H$. In other words, $\mathcal{K}(p)$ can be taken as a common field-of-definition of points of all such $\Gamma_\mathbb{Q}$-modules $H$.

Now assume that

(C) $\mathcal{K}(p)$ is totally ramified at $p$.

Under this assumption we have a natural identification $\text{Gal}(\mathcal{K}(p)/\mathbb{Q}) = \text{Gal}(\mathcal{K}(p)/F/F)$, that is the Galois group of the global extension $\mathcal{K}(p)/\mathbb{Q}$ comes as the Galois group of its completion over $F$. Therefore, we can identify $\mathcal{M}_\Gamma^{\mathbb{Q}}[1]$ with the full subcategory of $\text{CM}_{\Gamma_F}$, consisting of $(H_{st}, H^0_{st}, i)$ such that $pH_{st} = 0$ and all points of $H_{st}$ are defined over $\mathcal{K}(p)F$. In other words, the objects of $\mathcal{M}_\Gamma^{\mathbb{Q}}[1]$ can be described via our local results about killed by $p$ subquotients of semistable representations of $\Gamma_F$.
Denote by $\mathbf{M}_\ell^{f \ell}[1]$ a full subcategory in $\mathbf{M}_\ell^{f}[1]$ which consists of killed by $p$ subquotients of $p$-divisible groups in the category $\mathbf{M}_\ell^{f}$. Let $F'$ be the maximal tamely ramified extension of $F$ in $\mathcal{K}(p)F$. Then $\text{Gal}(F'/F)$ is abelian group of order prime to $p$ (use that the residue field of $F'$ is algebraically closed) and $\text{Gal}(\mathcal{K}(p)F/F')$ is a $p$-group. This gives an abelian extension $\mathcal{K}'$ of $\mathbb{Q}$ in $\mathcal{K}(p)$ of prime-to-$p$ degree and such that $\mathcal{K}(p)/\mathcal{K}'$ is a $p$-extension. This extension is unramified outside $p$ and, therefore, it coincides (use class field theory) with $\mathbb{Q}(\zeta_p)$. In particular, all simple objects in $\mathbf{M}_\ell^{f}[1]$ are of the form $\mathcal{F}(j) = (\mathbb{F}_p(j), 0, 0)$ if $1 \leq j < p$ and $\mathcal{F}(0) = (\mathbb{F}_p(0), \mathbb{F}_p(0), \text{id})$ if $j = 0$.

Let $\mathbf{L}_\ell^{f}[1]$ and $\mathbf{L}_\ell'[1]$ be the full subcategories of $\mathbf{L}^{f}[1]$ mapped by the functor $\widetilde{\mathcal{V}}^f$ to the objects of $\mathbf{M}_\ell^{f}[1]$ and, resp., $\mathbf{M}_\ell^{f}[1]$. Clearly, $\mathbf{L}_\ell^{f}[1]$ is a full subcategory in $\mathbf{L}^{f}[1]$ and the only simple objects in these categories are $\mathcal{L}(r)$, where $r \in \{ j/(p - 1) \mid j = 0, 1, \ldots, p - 1 \}$.

Suppose $H^\infty = \{ H^{(n)}_\mathbb{Q}, n \} \_{n \geq 0}$ is a $p$-divisible group in the category $\mathbf{M}_\ell^{f}$. Here all $H^{(n)}_\mathbb{Q} = (H^{(n)}_\mathbb{Q}, \hat{H}^{(n)}_\text{st})$ are objects of the category $\mathbf{M}_\ell^{f}$. Let $\mathcal{L} \in \mathbf{L}_\ell^{f}[1]$ be such that $\widetilde{\mathcal{V}}^f(\mathcal{L}) = \hat{H}^{(1)}_\text{et}$. Note that the maximal etale subobject $\mathcal{L}^\text{et}$ of $\mathcal{L}$ is isomorphic to $\mathcal{L}(0)^{n_{\text{et}}}$, where $n_{\text{et}} = n_{\text{et}}(\mathcal{L}) \in \mathbb{Z}_{\geq 0}$, and $\mathcal{L}/\mathcal{L}^\text{et}$ has no simple subquotients isomorphic to $\mathcal{L}(0)$. Similarly, the corresponding maximal multiplicative quotient $\mathcal{L}^\text{m}$ is isomorphic to $\mathcal{L}(1)^{n_{\text{m}}}$, where $n_{\text{m}} = n_{\text{m}}(\mathcal{L}) \in \mathbb{Z}_{\geq 0}$, and the kernel of the canonical projection $\mathcal{L} \rightarrow \mathcal{L}^\text{m}$ has no simple subquotients isomorphic to $\mathcal{L}(1)$. Therefore, for any $\mathcal{M} \in \mathbf{L}_\ell^{f}[1]$,

$$\text{Ext}_{\mathbf{L}_\ell^{f}[1]}(\mathcal{L}(0), \mathcal{M}) = \text{Ext}_{\mathbf{L}_\ell^{f}[1]}(\mathcal{M}, \mathcal{L}(1)) = 0.$$ 

This implies that for any $H \in \mathbf{M}_\ell^{f}[1]$,

$$\text{Ext}_{\mathbf{M}_\ell^{f}[1]}(H, \mathcal{F}(0)) = \text{Ext}_{\mathbf{M}_\ell^{f}[1]}(\mathcal{F}(1), H) = 0.$$ 

Therefore, by Theorem A.5 of Appendix A there is an embedding of $p$-divisible groups $H^\infty,^m \subset H^\infty$, where $H^{(1)}^m = \mathcal{F}(1)^{n_{\text{et}}}$, and there is a projection of $p$-divisible groups $H^\infty \twoheadrightarrow H^\infty,^c\text{t}$, where $H^{(1)}^c\text{t} = \mathcal{F}(0)^{n_{\text{m}}}$. For similar reasons,

$$\text{Ext}_{\mathbf{M}_\ell^{f}[1]}(\mathcal{F}(0), \mathcal{F}(0)) = \text{Ext}_{\mathbf{M}_\ell^{f}[1]}(\mathcal{F}(1), \mathcal{F}(1)) = 0$$

and by Theorem A.4 of Appendix A, the corresponding $p$-divisible groups $H^\infty,^m_\mathbb{Q}$ and $H^\infty,^c\text{t}_\mathbb{Q}$ are unique. Therefore they coincide with the products of trivial $p$-divisible groups $(\mathbb{Q}_p/\mathbb{Z}_p)(p - 1)$ and, resp., $(\mathbb{Q}_p/\mathbb{Z}_p)(0)$.

We state this result in the following form.

**Proposition 5.1.** Under assumption (C), for any $p$-divisible group $H^\infty$ in the category $\mathbf{M}_\ell^{f}$ there is a filtration of $p$-divisible groups

$$H^\infty \supset H^\infty_1 \supset H^\infty_0$$

---

**Documenta Mathematica** 18 (2013) 547–619
such that $H_0^\infty = (\mathbb{Q}/\mathbb{Z}_p)(p-1)^n$, $H^\infty/H_1^\infty = (\mathbb{Q}/\mathbb{Z}_p)(0)^n$, and all simple subquotients of $H_1^\infty/H_0^\infty$ belong to $\{F_p(j)\}_{1 \leq j \leq p-2}$.

5.2. Assume that $p = 3$.

**Lemma 5.2.** $\mathcal{K}(3) = \mathbb{Q}(\sqrt[3]{3}, \zeta_3)$, where $\zeta_3$ is the 9-th primitive root of 1.

This Lemma will be proved in Subsection 5.3 below.

In particular, $\mathcal{K}(3)$ satisfies the assumption (C).

**Proposition 5.3.** If $H^\infty$ is a 3-divisible group in $\text{MF}^3_\mathcal{Q}$ then in its filtration from Proposition 5.1 the 3-divisible group $H^\infty = H_1^\infty/H_0^\infty$ is a product of finitely many trivial 3-divisible groups $(\mathbb{Q}_3/\mathbb{Z}_3)(1)$.

**Proof.** Let $\hat{\mathcal{L}}_3$ be the full subcategory of $\mathcal{L}_3[1]$ consisting of objects $\mathcal{L}$ such that $L^3 = L^e = 0$. This category has only one simple object $\mathcal{L}(1/2)$. Let $\hat{\text{MF}}_3$ be the full subcategory in $\text{MF}^3_\mathcal{Q}[1]$ consisting of the objects $\hat{\text{CV}}^\dagger(\mathcal{L})$, where $\mathcal{L} \in \hat{\mathcal{L}}_3$. Then $\hat{\mathcal{L}}_3$ and $\hat{\text{MF}}_3$ are antiequivalent categories and $\hat{H}^{(1)}(1) \in \hat{\text{MF}}_3$. By Theorems A.4 and A.5 our Proposition is implied by the following result.

**Proposition 5.4.** $\text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2), \mathcal{L}(1/2)) = 0$.

**Proof.** Consider the equivalence of the categories $\Pi : \mathcal{L}^\dagger \rightarrow \mathcal{L}^*$ from Corollary 3.10. This equivalence transforms the functor $\hat{\text{CV}}^\dagger$ into the functor $\text{CV}^*$ from Section 2, cf. the proof of Proposition 4.16. Therefore, the objects $\mathcal{L}$ of the category $\Pi(\hat{\mathcal{L}}_3) := \mathcal{L}_3^*$ are characterised by the condition that all points of $V^*(\mathcal{L})$ are defined over the field $K(3)$. The objects $\mathcal{L}$ of the category $\Pi(\mathcal{L}_3)(1)$ are characterised by the additional properties: they are all obtained by subsequent extensions via $\mathcal{L}(1/2)$ and $V^*(\mathcal{L})$ appears as a subquotient of $\Gamma_\mathcal{L}$ with Hodge-Tate weights from $[0,2]$.

Introduce the object $\mathcal{L}(1/2, 1/2) = (L, F(L), \varphi, N)$ of the category $\mathcal{L}_3^*$ as follows:

- $L = W_1l + W_1l$;
- $F(L)$ is spanned by $u_1$ and $u_1 + l$;
- $\varphi(u_1) = l$, $\varphi(u_1 + l) = l$;
- $N(l_1) \equiv 0 \mod u^3L$, $N(l_1) \equiv l_1 \mod u^3L$.

Clearly, $\mathcal{L}(1/2, 1/2)$ has a natural structure of an element of the group $\text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2), \mathcal{L}(1/2))$.

**Lemma 5.5.** a) $\mathcal{L}(1/2, 1/2) \in \mathcal{L}_3^*$; b) $\text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2), \mathcal{L}(1/2)) \cong \mathbb{Z}/3$ and is generated by the class of $\mathcal{L}(1/2, 1/2)$; c) $\text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2), \mathcal{L}(1/2, 1/2)) = \text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2, 1/2), \mathcal{L}(1/2)) = 0$.

This Lemma will be proved in Subsection 5.4 below.

Lemma 5.5 implies that $\text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1/2, 1/2), \mathcal{L}(1/2, 1/2)) = 0$ and, therefore, any object $\mathcal{L}$ of $\mathcal{L}_3^*$ is the product of several copies of $\mathcal{L}(1/2)$ and $\mathcal{L}(1/2, 1/2)$.
Suppose $\mathcal{L} = \mathcal{L}_1 \times L(1/2,1/2) \in \hat{\mathcal{L}}_Q^*$. Then there is a 3-divisible group $\tilde{H}^\infty$ in $\check{\text{M}^{\Gamma}_2}$ such that $\tilde{H}^{(1)} = H' \times H(1/2,1/2)$, where $H'$ and $H(1/2,1/2) = CV^*(L(1/2,1/2))$ belong to $\check{\text{M}^{\Gamma}_2}$. Clearly, we have $\text{Ext}_{\check{\text{M}^{\Gamma}_2}(1)}(H',H(1/2,1/2)) = 0$ and applying Theorem A.5 we obtain a 3-divisible group $H^\infty$ in $\check{\text{M}^{\Gamma}_2}$ such that $H^{(1)} = H(1/2,1/2)$. This implies the existence of 2-dimensional semi-stable (and non-crystalline) representation of $\Gamma_F$ with the only simple subquotient $\mathbb{F}_3(1)$, that is for any Galois invariant lattice $T$ of such representation, the $\Gamma_F$-module $T/3T$ has semi-simple envelope $\mathbb{F}_3(1) \times \mathbb{F}_3(1)$. This situation appears as a very special case of Breuil’s description of 2-dimensional semi-stable (and non-crystalline) representations. According to Theorem 6.1.1.2 of [5] the corresponding semi-simple envelope is either $\mathbb{F}_3(0) \times \mathbb{F}_3(1)$ or $\mathbb{F}_3(1) \times \mathbb{F}_3(2)$. The proposition is proved. □

Now our main Theorem appears as the following Corollary.

**Corollary 5.6.** If $Y$ is a projective variety with semi-stable reduction modulo 3 and good reduction modulo all primes $l \neq 3$ then $h^2(Y_\mathbb{C}) = h^{1,1}(Y_\mathbb{C})$.

**Proof.** Indeed, let $V$ be the $\mathbb{Q}_3[\Gamma_F]$-module of 2-dimensional etale cohomology of $Y$. Then it is a semi-stable representation of $F$ and its $\Gamma_F$-invariant lattice determines a 3-divisible group in the category $\check{\text{M}^{\Gamma}_2}$. By Proposition 5.3 this 3-divisible group can be built from the Tate twists $(\mathbb{Q}_3/\mathbb{Z}_3)(i)$, $i = 0,1,2$. Equivalently, all $\Gamma_F$-equivariant subquotients of $V$ are $\mathbb{Q}_3(i)$ with $i = 0,1,2$. Applying the Riemann Conjecture (proved by Deligne) to the reductions $Y \text{ mod } l$ with $l \neq 3$, we obtain that $\mathbb{Q}(0)$ and $\mathbb{Q}(2)$ do not appear. Therefore, $V$ is the product of finitely many $\mathbb{Q}_3(1)$ and $h^2(Y_\mathbb{C}) = h^{1,1}(Y_\mathbb{C})$. □

**5.3. Proof of Lemma 5.2.** Use the ramification estimate from Subsection 2.9 to deduce that the normalized discriminant of $\mathcal{K}(3)$ over $\mathbb{Q}$ satisfies the inequality $|D(\mathcal{K}(3)/\mathbb{Q})|^{[\mathcal{K}(3):\mathbb{Q}]^{-1} < 3^{3-1/3} = 18.72075}$. Then Odlyzko estimates imply that $|\mathcal{K}(3) : \mathbb{Q}| < 230 [11]$.

Let $K_0 = \mathbb{Q}(\zeta_3)$ and $K_1 = \mathbb{Q}(\sqrt{3}, \zeta_3)$. Then $K_0$ is the maximal abelian extension of $\mathbb{Q}$ in $\mathcal{K}(3)$ and $K_1 \subset \mathcal{K}(3)$. We have also the inequality $[\mathcal{K}(3) : K_1] < 60$ and, therefore, $\text{Gal}(\mathcal{K}(3)/\mathbb{Q})$ is soluble. Prove that $K_1 = \mathcal{K}(3)$.

Suppose the field $K_2$ is the maximal abelian extension of $K_1$ in $\mathcal{K}(3)$. One can apply the computer package SAGE to prove that the group of classes of $K_1$ is trivial. Therefore, $K_2$ is totally ramified at 3 and $\text{Gal}(K_2/\mathbb{Q})$ coincides with the Galois group of the corresponding 3-completions. In particular, the maximal tamely ramified subextension of these completions comes from $\mathbb{Q}(\zeta_3)$ and, therefore, $K_2/K_1$ is 3-extension. Therefore, there is an $\eta \in \mathcal{O}_{K_1}^*$ such that $K_1(\sqrt[3]{\eta}) \subset K_2$. Then a routine computation shows that the normalized discriminant for $K_1(\sqrt[3]{\eta})$ over $\mathbb{Q}$ is less than $3^{3-1/3}$ if and only if $\eta \equiv 1 \text{ mod } \mathcal{O}_{K_1}^*(1 + 3 \mathcal{O}_{K_1})$. The Lemma will be proved if we show that such $\eta \in \mathcal{O}_{K_1}^*$. (This is equivalent to the Leopoldt Conjecture for the field $K_1$.)
was proved via a SAGE computer program written by R.Henderson (Summer-2009 Project at Durham University supported by Nuffield Foundation). This program, cf. Appendix B, constructed a basis $\varepsilon_i \mod O_K^{x^i}$, $1 \leq i \leq 9$, of $O_K^{x^9}/O_K^{x^3}$ such that $18v_3(\varepsilon_i - 1)$ takes values in the set $\{1, 2, 4, 5, 7, 8, 10, 13, 16\}$. In other words, $v_3(\eta - 1) \geq 1 > 16/18$ implies that $\eta \in O_K^{x^3}$.

Lemma 5.2 is proved.

5.4. Proof of Lemma 5.5. a) Use the notation from the definition of the functor $\mathcal{V}^f$ in Subsection 4. If $f_0 \in \mathcal{V}^f(\mathcal{L}(1/2, 1/2))$ then the correspondence $f_0 \mapsto (f_0(l_1), f_0(l_2))$ identifies $\mathcal{V}^f(\mathcal{L}(1/2, 1/2))$ with the $\mathbb{F}_2$-module of couples $(X_{10}, X_0) \in (R/x_0)^2$ such that $X_{10}^3/x_0^3 = X_{10}$ and $(X_0^3 + X_{10})/x_0^3 = X_0$. Then the $\mathbb{F}_2[\Gamma_F]$-module $\mathcal{V}^f(\mathcal{L}(1/2, 1/2))$ is identified with the module formed by the images of all $(X_{10}, X_0 + X_{10}Y) \in (R/\mathfrak{m})^2$ in $R/\mathfrak{m} = R_0^x/(x_0^3m_R + x_0^3m_RY + x_0m_RY^2)$. In particular, the corresponding $\Gamma_F$-action on $\mathcal{V}^f(\mathcal{L}(1/2, 1/2))$ comes from the natural $\Gamma_F$-equivariant identification

$$\iota : m_R/(x_0^3m_R) \to \mathfrak{m}/3\mathfrak{m},$$

where $\mathfrak{m}$ is the maximal ideal of the valuation ring of $\mathbb{Q}_3$. This isomorphism $\iota$ comes from the map $r \mapsto r^{(1)}$, where for $r = \lim_{n \to \infty} (r_n \mod p)$, $r^{(1)} := \lim_{n \to \infty} r_n^{3n+1}$.

Then Hensel’s Lemma implies the existence of unique $Z_{10}, Z_0 \in \mathfrak{m}$ such that the following equalities hold $\iota(X_{10} \mod x_0^3m_R) = Z_{10} \mod 3\mathfrak{m}$, $\iota(X_0 \mod x_0^3m_R) = Z_0 \mod 3\mathfrak{m}$, $Z_{10} + 3Z_0 = 0$ and $Z_0^3 + 3Z_0 = -Z_{10}$.

Clearly, $F(Z_{10}, Z_0) = F(\zeta_3)$. Therefore, if $\tau \in \Gamma_F$ is such that $\tau(\zeta_3) = \zeta_3$ then $\tau(X_{10}) = X_0$ and $\tau(X_0) = X_{10}$. Finally, it follows directly from definitions that if $\tau(\sqrt{3}) = \sqrt{3}$ then $\tau$ acts as identity on the image of $Y$ in $R_0^x$. The part a) of the Lemma is proved.

b) Suppose $\mathcal{L} = (L, F(L), \varphi, N) \in \text{Ext}_{\mathcal{L}_3}(\mathcal{L}(1), \mathcal{L}(1))$. Then $L = W_1l \oplus W_1l_1$, there is an $w \in W_1$ such that $F(L)$ is spanned by $ul_1$ and $ul_1 + w_1l_1$ over $W_1$, and one has $\varphi(w_1l_1) = l_1, \varphi(ul + w_1l_1) = l, N(l_1) \in w^3L$ and $N(l_1) \equiv w^3l_1 \mod w^3L$. Notice that $\mathcal{L}$ splits in $\mathcal{L}_3$ if $w \in uW_1$. Therefore, we can assume that $w = \alpha \in k$.

Then the field-definition of all points of $\mathcal{V}^f(\mathcal{L})$ contains the field-definition of all solutions $(X_1, X) \mod x_0^3m_R \in (R/x_0^3m_R)^2$ of the following congruences: $X_1^3/x_0^3 \equiv X_1 \mod x_0^3m_R$ and $(X^3 + \alpha^3X_1)/x_0^3 \equiv X \mod x_0^3m_R$. Let $x_1 \in R$ be such that $x_1^3 = x_0$. Then we can take $X_1 = x_1^3$ and for $T = X/x_1^3$ one has the following Artin-Schreier-type congruence:

$$T^3 - T \equiv -\alpha^3/x^6 \mod m_R.$$

Using calculations from above part a) we can conclude that $\mathcal{L} \in \mathcal{L}_3^0$ if and only if the field-definition of $T \mod m_R$ over $k((x_1))$ belongs to the field-definition of $T_0 \mod m_R$ over $k((x_1))$, where $T_3^3 - T_0 \equiv -x_1^{-6} \mod m_R$. By Artin-Schreier theory this happens if and only if $\alpha \in \mathbb{F}_3$ and, therefore, $\mathcal{L} \simeq \mathcal{L}(1/2, 1/2)$. 

---

**Documenta Mathematica 18 (2013) 547–619**
c) Suppose \( L = (L, F(L), \varphi, N) \in \text{Ext}_{\mathcal{L}}(L(1/2), L(1/2, 1/2)). \)

Then we can assume that:

- \( L = W_1 l \oplus W_1 l_1 \oplus W_1 m; \)
- \( F(L) \) is spanned over \( W_1 \) by \( ul, ul_1 \) and \( um + wl + w_1 l_1 \) with \( w, w_1 \in W_1; \)
- \( \varphi(ul) = l, \varphi(ul_1) = l \) and \( \varphi(um + wl + w_1 l_1) = m. \)

Then the condition \( u^2 m \in F(L) \) implies that \( w_1l \in F(L), \) or \( w \in uW_1 \) and we can assume that \( w = 0. \) Then the submodule \( W_1 m + W_1 l_1 \) determines a subobject \( L' \) of \( L, L' \in \mathcal{L} \) and using calculations from b) we conclude that \( w_1 \in \mathbb{F}_3 \) mod \( uW_1. \) Therefore, we can assume that \( w_1 = \alpha \in \mathbb{F}_3 \) and for \( m' = m - \alpha l \) we have \( m' \in F(L) \) and \( \varphi(m') = m', \) i.e. \( L \) is a trivial extension. Now suppose \( L = (L, F(L), \varphi, N) \in \text{Ext}_{\mathcal{L}}(L(1/2, 1/2), L(1/2)). \)

Then we can assume that:

- \( L = W_1 m \oplus W_1 m_1 \oplus W_1 l; \)
- \( F(L) \) is spanned over \( W_1 \) by \( ul, um_1 + wt \) and \( um + m_1 + w_1 l \) with \( w, w_1 \in W_1; \)
- \( \varphi(ul) = l, \varphi(um_1 + wt) = m_1 \) and \( \varphi(um + m_1 + w_1 l) = m. \)

Again, the condition \( u^2 m \in F(L) \) implies that \( w \in uW_1 \) and, therefore, we can assume that \( w = 0. \) Then the quotient module \( L/W_1 m_1 \) is the quotient of \( L \) in the category \( \mathcal{L}. \) This quotient must belong to the subcategory \( \mathcal{L}/. \) This implies that \( w_1 \in \mathbb{F}_3 \) mod \( uW_1, \) and, as earlier, \( L \) becomes a trivial extension. The Lemma is completely proved.

Appendix A. \( p \)-divisible groups in pre-abelian categories

A.1. Short exact sequences in pre-abelian categories.

A.1.1. Pre-abelian categories. Introduce the concept of special pre-abelian category following mainly [28], cf. also [25, 26, 29]. Remind that a category \( S \) is pre-abelian if it is additive and for any morphism \( u \in \text{Hom}_S(A, B), \) there exist \( \text{Ker} u = (A_1, i) \) and \( \text{Coker} u = (B_1, j), \) where \( i \in \text{Hom}_S(A_1, A) \) and \( j \in \text{Hom}_S(B_1, B). \) For any objects \( A, B \in S, \) let \( A \coprod B \) and \( A \coprod B \) be their product and coproduct, respectively. There is a canonical isomorphism \( A \coprod B \simeq A \coprod B \) in \( S. \) More generally, for given morphisms:

- \( \alpha \in \text{Hom}_S(C, A), \beta \in \text{Hom}_S(C, B), \) there is a fibered coproduct \( (A \coprod_C B, i_A, i_B), \) with \( i_A \in \text{Hom}_S(A, A \coprod_C B), i_B \in \text{Hom}_S(B, A \coprod_C B) \) which completes the diagram \( A \xleftarrow{\alpha} C \xrightarrow{\beta} B \) to a cocartesian square;

- \( f \in \text{Hom}_S(A, C) \) and \( g \in \text{Hom}_S(B, C), \) there is a fibered product \( (A \coprod_C B, p_A, p_B), \) with \( p_A \in \text{Hom}_S(A, A \coprod_C B), p_B \in \text{Hom}_S(A, A \coprod_C B), \) which completes the diagram \( A \xrightarrow{f} C \xleftarrow{g} B \) to a cartesian square.

Suppose \( i \in \text{Hom}_S(A_1, A), f \in \text{Hom}_S(A_1, B) \) and \( (B \coprod_A A, i_A, i_B) \) is their fibered coproduct. If \( (A_2, j) = \text{Coker} i \) then there is a morphism \( j_B : \)

\[ \text{Documenta Mathematica 18 (2013) 547–619} \]
Varieties with Bad Reduction at 3 Only

$B \coprod_{A_1} A \to A_2$ such that the following diagram

\[
\begin{array}{ccccccccc}
A_1 & \xrightarrow{i} & A & \xrightarrow{j} & A_2 \\
| & & \downarrow f & & \downarrow i_A & & \downarrow id \\
B & \xrightarrow{i_B} & B \coprod_{A_1} A & \xrightarrow{j_B} & A_2 \\
\end{array}
\]

is commutative (use the zero morphism from $B$ to $A_2$). A formal verification shows that $(A_2, j_B) = \text{Coker} i_B$.

Suppose $j \in \text{Hom}_S(A, A_2), g \in \text{Hom}_S(B, A_2)$ and $(B \coprod_{A_2} A, p_B, p_A)$ is their fibered product. If $(A_1, i) = \text{Ker} j$ then there is an $i_B : A_1 \to B \coprod_{A_1} A$ (use the zero map from $A_1$ to $B$) such that the following diagram

\[
\begin{array}{ccccccccc}
A_1 & \xrightarrow{i} & A & \xrightarrow{j} & A_2 \\
| & & \downarrow id & & \downarrow p_A & & \downarrow p_B & & \downarrow g \\
A_1 & \xrightarrow{i_B} & B \coprod_{A_1} A & \xrightarrow{j_B} & A_2 & \xrightarrow{p_B} & B \\
\end{array}
\]

is commutative and $(A_1, i_B) = \text{Ker} p_B$.

A.1.2. **Strict morphisms.** A morphism $u \in \text{Hom}_S(A, B)$ is strict if the canonical morphism $\text{Coim} u = \text{Coker}(\text{Ker} u) \to \text{Im} u = \text{Ker}(\text{Coker} u)$ is isomorphism. One can verify that always $\text{Ker} u = (A_1, i)$ is a strict monomorphism and $\text{Coker} u = (B_1, j)$ is a strict epimorphism. By definition, a sequence of objects and morphisms

\[(A.1) \quad 0 \to A_1 \xrightarrow{i} A \xrightarrow{j} A_2 \to 0\]

in $S$ is short exact if $(A_1, i) = \text{Ker} j$ and $(A_2, j) = \text{Coker} i$. In particular, any strict monomorphism (resp. strict epimorphism) can be included in a short exact sequence.

**Definition.** A pre-abelian category is special if it satisfies the following two axioms:

- **SP1.** if $\alpha : C \to A$ is strict monomorphism then $i_B : B \to A \coprod_C B$ is also strict monomorphism;
- **SP2.** if $f : A \to C$ is strict epimorphism then $p_B : A \coprod_C B \to B$ is also strict epimorphism.

**Remark.** A typical example of pre-abelian special category is the category of modules with filtration.
Consider short exact sequence (A.1) in $S$. If $f \in \text{Hom}_S(A_1, B)$ then we have the following commutative diagram

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & A_1 & \longrightarrow & A & \longrightarrow & A_2 & \longrightarrow & 0 \\
& & \downarrow f & & \downarrow i & & \downarrow j & & \\
0 & \longrightarrow & B & \longrightarrow & A \prod_i A_i B & \longrightarrow & A_2 & \longrightarrow & 0 \\
\end{array}
\]

Then $j_B = \text{Coker}i_B$ is strict epimorphism and by axiom SP1, $i_B$ is strict monomorphism. Then $\text{Ker}j_B = \text{Ker}(\text{Coker}i_B) = \text{Im}i_B = (B, i_B)$ and, therefore, the lower row of the above diagram is exact.

Dually, for any $g \in \text{Hom}_S(B, A_2)$ there is a commutative diagram

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & A_1 & \longrightarrow & A & \longrightarrow & A_2 & \longrightarrow & 0 \\
& & \uparrow id & & \uparrow p_A & & \uparrow g & & \\
0 & \longrightarrow & A_1 & \longrightarrow & A \prod_i A_i B & \longrightarrow & B & \longrightarrow & 0 \\
\end{array}
\]

where $i_B = \text{Ker}j_B$ is strict monomorphism, by Axiom SP2, $p_B$ is strict epimorphism and the lower row of this diagram is exact.

With relation to above diagram (A.2) we have the following properties.

\textbf{Lemma A.1.} a) The natural map $\delta : \text{Ker}f \longrightarrow \text{Ker}i_A$ is isomorphism;

b) if $f$ is strict epimorphism then $\text{Ker}i_A$ is also strict epimorphism.

\textbf{Proof.} a) Suppose that $\text{Ker}f = (K_1, \alpha_1)$ and $\text{Ker}i_A = (K, \alpha)$. Then $\delta : \text{Ker}f \longrightarrow \text{Ker}i_A$ appears from the universal property of $(K, \alpha)$ because $i_A \circ i \circ \alpha_1 = i_B \circ f \circ \alpha_1 = 0$. The relation $j \circ \alpha = j_B \circ i_A \circ \alpha = 0$ implies the existence of $\tilde{\alpha} : K \longrightarrow A_1$ such that $i \circ \tilde{\alpha} = \alpha$. Then $i_B \circ f \circ \tilde{\alpha} = i_A \circ \alpha = 0$ and $f \circ \tilde{\alpha} = 0$ (use that $i_B$ is monomorphism). By the universal property of $(K_1, \alpha_1)$ this gives the map $\delta_1 : K \longrightarrow K_1$ such that $\alpha_1 \circ \delta_1 = \tilde{\alpha}$ and this map is inverse to $\delta$.

b) Suppose $f$ is a strict epimorphism, then $(B, f) = \text{Coker} \alpha_1$. Let $(\tilde{C}, \tilde{j}) = \text{Coker} \alpha$. By functoriality, there is $\varepsilon : B \longrightarrow \tilde{C}$ such that $\varepsilon \circ f = \tilde{j} \circ i$. Then $\tilde{j}$ and $\varepsilon$ define a unique $\omega : A \prod_i A_i B \longrightarrow \tilde{C}$ such that $\omega \circ i_B = \varepsilon$ and $\omega \circ i_A = \tilde{j}$. But $i_A \circ \alpha = 0$ implies by the universal property of $(\tilde{C}, \tilde{j})$ the map $\omega_1 : \tilde{C} \longrightarrow A \prod_i A_i B$ and one can verify that it is inverse to $\omega$. \hfill \square

\textbf{Remark.} If $f$ is strict monomorphism then $i_A$ is also strict monomorphism by axiom SP2.

With relation to diagram (A.3) we have the following Lemma which is dual to above Lemma A.1.

\textbf{Lemma A.2.} a) The natural map $\text{Coker}p_A \longrightarrow \text{Coker}g$ is isomorphism; b) if $g$ is strict epimorphism then $p_A$ is also strict epimorphism.

\textbf{Proof.} The proof is dual to the proof of Lemma A.1. \hfill \square
Lemma A.3. A composition of two strict monomorphisms (resp., epimorphisms) is again strict monomorphism (resp., epimorphism).

Proof. It will be sufficient to consider only the case of monomorphisms. Suppose $i \in \text{Hom}_S(A_1, A)$ and $i_1 \in \text{Hom}_S(A, B)$ are two strict monomorphisms. Construct the following commutative diagram:

\[
\begin{array}{c}
0 & \rightarrow & A_1 & \xrightarrow{i} & A & \xrightarrow{j} & A_2 & \rightarrow & 0 \\
& & \downarrow{\beta} & & \downarrow{i_1} & & \downarrow{i_{A_2}} & & \\
0 & \rightarrow & K & \xrightarrow{\alpha} & B & \xrightarrow{i_B} & A_2 \coprod_A B & \rightarrow & 0 \\
& & \downarrow{j_1} & & \downarrow{j} & & \downarrow{\gamma} & & \\
& & C_1 & \xrightarrow{\gamma} & C & & & & \\
\end{array}
\]

Here $j = \text{Coker} i$ is strict epimorphism and the upper right square is co-cartesian. Therefore, $i_B$ is strict epimorphism and we obtain the second line which is short exact. The morphisms $i_1$ and $i_{A_2}$ are strict monomorphisms and we can complete our diagram by $(C_1, j_1) = \text{Coker} i_1$ and $(C, j) = \text{Coker} i_{A_2}$. The maps $\beta$ and $\gamma$ are obtained by functoriality and we have proved that they are isomorphisms. Therefore, $i_1 \circ i = \beta \circ \alpha$ is strict (use that $\alpha = \text{Ker} i_B$ is strict). \qed

A.1.3. Bifunctor $\text{Ext}_S$. If $S$ is pre-abelian category then in the following commutative diagram with exact rows

\[
\begin{array}{c}
0 & \rightarrow & A_1 & \xrightarrow{id} & A & \xrightarrow{f} & A_2 & \rightarrow & 0 \\
0 & \rightarrow & A_1 & \xrightarrow{id} & A' & \xrightarrow{id} & A_2 & \rightarrow & 0 \\
\end{array}
\]

the morphism $f$ is isomorphism. Therefore, we can introduce the set of equivalence classes of short exact sequences $\text{Ext}_S(A_2, A_1)$. This set is functorial in both arguments due to axioms SP1 and SP2.

Suppose the objects of $S$ are provided with commutative group structure respected by morphisms of $S$. Then for any $A, B \in S$, $\text{Ext}_S(A, B)$ has a natural group structure, where the class of split short exact sequences plays a role of neutral element. Remind that the sum $\varepsilon_1 + \varepsilon_2$ of two extensions $\varepsilon_1 : 0 \rightarrow A_1 \xrightarrow{\iota'} A' \xrightarrow{\iota''} A_2 \rightarrow 0$ and $\varepsilon_2 : 0 \rightarrow A_1 \xrightarrow{\iota'''} A'' \xrightarrow{\iota'''} A_2 \rightarrow 0$ is the lower line of the following commutative diagram relating the rows
l = ε₁ ⊕ ε₂, ∇⁺(l) and (+), ∇⁺(l),

\[ l : 0 \rightarrow A_1 \prod_{A_1} A_2 \rightarrow 0 \]
\[ \nabla⁺(l) : 0 \rightarrow A_1 \prod_{A_1} A_2 \rightarrow 0 \]
\[ (+), \nabla⁺(l) : 0 \rightarrow A_1 \rightarrow A_2 \rightarrow 0 \]

Here ∇ is the diagonal morphism, + is the morphism of the group structure on S. For any \( f \in \text{Hom}_S(A_1, B) \) and \( g \in \text{Hom}_S(B, A_2) \) the corresponding morphisms \( f_* : \text{Ext}_S(A_2, A_1) \rightarrow \text{Ext}_S(A_2, B) \) and \( g^* : \text{Ext}_S(A_2, A_1) \rightarrow \text{Ext}_S(B, A_1) \) are homomorphisms of abelian groups. The proof is completely formal and goes along the lines of [27].

Suppose \( \varepsilon \in \text{Ext}_S(A_2, A_1) \), then the extension \( \varepsilon + (-id)^* \varepsilon \) splits. We shall need below the following explicit description of this splitting.

Let \( \varepsilon : 0 \rightarrow A_1 \rightarrow A \rightarrow A_2 \rightarrow 0 \). Then \( \varepsilon + (-id)^* \varepsilon \) is the lower row in the following diagram

\[ 0 \rightarrow A_1 \prod_{A_1} A_2 \rightarrow A_2 \rightarrow 0 \]
\[ 0 \rightarrow A_1 \rightarrow A_0 \rightarrow A_2 \rightarrow 0 \]

where the left vertical arrow is the cokernel of the diagonal embedding \( \nabla : A_1 \rightarrow A_1 \prod_{A_1} A_1. \) One can see that the epimorphic map \( A_0 \rightarrow A_1 \), which splits the lower exact sequence, is induced by the morphism \( p_1 - p_2 : A \prod_{A_2} A \rightarrow A. \)

Finally, one can apply Serre’s arguments [30] to obtain for any short exact sequence \( 0 \rightarrow A_1 \rightarrow A \rightarrow A_2 \rightarrow 0 \) and any \( B \in S \), the following standard 6-terms exact sequences of abelian groups

\[ 0 \rightarrow \text{Hom}_S(B, A_1) \xrightarrow{i_*} \text{Hom}_S(B, A) \xrightarrow{j_*} \text{Hom}_S(B, A_2) \]
\[ \xrightarrow{\delta} \text{Ext}_S(B, A_1) \xrightarrow{i_*} \text{Ext}_S(B, A) \xrightarrow{j_*} \text{Ext}_S(B, A_2) \]
\[ 0 \rightarrow \text{Hom}_S(A_2, B) \xrightarrow{j^*} \text{Hom}_S(A, B) \xrightarrow{i^*} \text{Hom}_S(A_1, B) \]
\[ \xrightarrow{\delta} \text{Ext}_S(A_2, B) \xrightarrow{j^*} \text{Ext}_S(A, B) \xrightarrow{i^*} \text{Ext}_S(A_1, B) \]

A.2. \( p \)-DIVISIBLE GROUPS. In this section \( S \) is a special pre-abelian category consisting of group objects. Denote by \( S_1 \) the full subcategory of objects killed by \( p \) in \( S \), where \( p \) is a fixed prime number. Clearly, \( S_1 \) is again special pre-abelian.
A.2.1. Basic definitions. Consider an inductive system \((C^{(n)}, i^{(n)})_{n \geq 0}\) of objects of \(S\), where \(C^{(0)} = 0\) and all \(i^{(n)} : C^{(n)} \to C^{(n+1)}\) are strict monomorphisms. Let for all \(n \geq m \geq 0\), \(i_{mn} = i^{(n-1)} \circ \cdots \circ i^{(m+1)} \circ i^{(m)} \in \text{Hom}_S(C^{(m)}, C^{(n)})\). Then all \(i_{mn}\) are strict monomorphisms. Follow Tate’s paper [Ta] to define a \(p\)-divisible group in \(S\) as an inductive system \((C^{(n)}, i^{(n)})_{n \geq 0}\) such that for all \(0 \leq m \leq n\),

a) \(\text{Coker } i_{mn} = (C^{(n-m)}, j_{n,n-m})\), i.e. there are short exact sequences:

\[
0 \to C^{(m)} \xrightarrow{i_{mn}} C^{(n)} \xrightarrow{j_{n,m-n}} C^{(n-m)} \to 0
\]

b) there are commutative diagrams

\[
\begin{array}{ccc}
C^{(n)} & \xrightarrow{p^m \text{id}_{C^{(n)}}} & C^{(n)} \\
\downarrow j_{n,n-m} & & \downarrow \text{id} \\
C^{(n-m)} & & C^{(n-m)}
\end{array}
\]

The above definition implies the existence of the following commutative diagrams with exact rows (where \(m \leq n \leq n_1\)):

\[
\begin{array}{cccc}
0 & \to & C^{(m)} & \xrightarrow{i_{mn}} C^{(n)} & \xrightarrow{j_{n,m-n}} C^{(n-m)} & \to & 0 \\
0 & \to & C^{(m)} & \xrightarrow{i_{m1}} C^{(n_1)} & \xrightarrow{j_{n_1,m-n_1}} C^{(n_1-m)} & \to & 0 \\
0 & \to & C^{(n)} & \xrightarrow{i_{n1}} C^{(n_1)} & \xrightarrow{j_{n_1,m-n_1}} C^{(n_1-m)} & \to & 0 \\
0 & \to & C^{(m)} & \xrightarrow{i_{m,n+m-n_1}} C^{(m+n_1-n)} & \xrightarrow{j_{m+n_1-n,m-n_1}} C^{(m+n_1-n,m-n_1)} & \to & 0 \\
\end{array}
\]

Also, for all \(n \geq m \geq 0\), one has

• \((C^{(m)}, i_{mn}) = \text{Ker}(p^m \text{id}_{C^{(m)}}), (C^{(m)}, j_{mn}) = \text{Coker}(p^m \text{id}_{C^{(m)}})\);

• \(i_{mn} = i_{n-1,n} \circ \cdots \circ i_{m,m+1} \circ j_{m,n} = j_{m+1,n} \circ \cdots \circ j_{n,1}\).

The set of \(p\)-divisible groups in \(S\) has a natural structure of category. This category is pre-abelian. In particular,

\[
0 \to (C^{(n)}, i^{(n)})_{n \geq 0} \xrightarrow{(\gamma_n)_{n \geq 0}} (C^{(n)}, i^{(n)})_{n \geq 0} \xrightarrow{(\delta_n)_{n \geq 0}} (C^{(n)}, i^{(n)})_{n \geq 0} \to 0
\]

is a short exact sequence of \(p\)-divisible groups iff for all \(n \geq 1\), there are the following commutative diagrams with short exact rows in \(S\)

\[
\begin{array}{cccc}
0 & \to & C^{(n)} & \xrightarrow{\gamma_n} C^{(n)} & \xrightarrow{\delta_n} C^{(n)} & \xrightarrow{\gamma_{n+1}} C^{(n+1)} & \to & 0 \\
0 & \to & C^{(n+1)} & \xrightarrow{\gamma_{n+1}} C^{(n+1)} & \xrightarrow{\delta_{n+1}} C^{(n+1)} & \to & 0 \\
\end{array}
\]
A.2.2. A property of uniqueness of $p$-divisible groups.

**Theorem A.4.** Let $D$ be an object of $S_1$ such that $\text{Ext}_{S_1}(D,D) = 0$. If $(C^{(n)}, i^{(n)})_{n \geq 0}$ and $(C^{(n)}, i^{(n)})_{n \geq 0}$ are $p$-divisible groups in $S$ such that $C^{(1)} \simeq C^{(1)}_1 \simeq D$ then these $p$-divisible groups are isomorphic.

**Proof.** We must prove that for all $n \geq 1$, there are isomorphisms $f_n : C^{(n)} \to C^{(n)}_1$ such that $i^{(n)}_1 \circ f_n = f_{n+1} \circ i^{(n)}$. Suppose $n_0 \geq 1$ and all such isomorphisms have been constructed for $1 \leq n \leq n_0$. Therefore, we can assume that $C^{(n)} = C^{(1)}_1$ for $1 \leq n \leq n_0$. Consider the following commutative diagrams with exact rows:

(A.5) \[
\begin{array}{ccccccccc}
0 & \xrightarrow{i_1} & C^{(n_0+1)} & \xrightarrow{j_1} & C^{(n_0)} & \xrightarrow{j^{(n_0-1)}} & 0 \\
\quad \downarrow{\text{id}} & & \quad \downarrow{i^{(n_0)}} & & \quad \downarrow{j^{(n_0-1)}} & & \\
0 & \xrightarrow{i} & C^{(n)} & \xrightarrow{j} & C^{(n-1)} & \xrightarrow{j^{(n-1)}} & 0 \\
\end{array}
\]

(A.6) \[
\begin{array}{ccccccccc}
0 & \xrightarrow{i'_1} & C^{(n_0+1)}_1 & \xrightarrow{j'_1} & C^{(n_0)} & \xrightarrow{j'_{(n_0-1)}} & 0 \\
\quad \downarrow{\text{id}} & & \quad \downarrow{i^{(n_0)}} & & \quad \downarrow{j^{(n_0-1)}} & & \\
0 & \xrightarrow{i} & C^{(n)} & \xrightarrow{j} & C^{(n-1)} & \xrightarrow{j^{(n-1)}} & 0 \\
\end{array}
\]

Here in standard notation of Subsection A.2.1, $i_1 = i_{1,n_0+1}$, $i'_1 = i'_{1,n_0+1}$, $i = i_{1,n_0}$, $j = j_{n_0,n_0-1}$, $j_1 = j_{n_0+1,n_0}$ and $j'_1 = j'_{n_0+1,n_0}$ (the dash means that the corresponding morphism is related to the second $p$-divisible group). We must construct an isomorphism $f_{n_0+1} : C^{(n_0+1)} \to C^{(n_0+1)}_1$ such that $f_{n_0+1} \circ i^{(n_0)} = i^{(n_0)}_1$. Consider the following commutative diagram obtained from above two diagrams

(A.7) \[
\begin{array}{ccccccccc}
0 & \xrightarrow{i} & C^{(1)} & \xrightarrow{j} & C^{(n)} & \xrightarrow{j^{(n-1)}} & 0 \\
\downarrow{\text{id}} & & \quad \downarrow{i^{(n_0)}} & & \quad \downarrow{j^{(n_0-1)}} & & \\
0 & \xrightarrow{i} & C^{(n_0)} & \xrightarrow{j} & C^{(n_0-1)} & \xrightarrow{j^{(n_0-1)}} & 0 \\
\end{array}
\]

Notice that the morphisms of multiplication by $p$ in $C^{(n_0+1)}$ and $C^{(n_0+1)}_1$ can be factored as follows

\[
\begin{array}{ccccccccc}
C^{(n_0+1)} & \xrightarrow{p} & C^{(n_0+1)} & \xrightarrow{j_1} & C^{(n_0)} & \xrightarrow{i^{(n_0)}} & 0 \\
\downarrow{j_1} & & \quad \downarrow{i^{(n_0)}} & & \quad \downarrow{j^{(n_0)}} & & \\
C^{(n_0)} & \xrightarrow{p} & C^{(n_0+1)}_1 & \xrightarrow{j'_1} & C^{(n_0)} & \xrightarrow{i^{(n_0)}} & 0 \\
\end{array}
\]
Therefore, we obtain the following commutative diagram

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{
C_{(n_0)} \times \prod C_{(n_0)} & C_{(n_0+1)} \\
\downarrow & \downarrow \\
C_{(n_0)} \times \prod C_{(n_0)} & C_{(n_0+1)} \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{
& \ar[r]^{p} & \\
\downarrow & & \\
& \ar[r]^{i^{(n_0)}_{1} \times i^{(n_0)}} & \\
\downarrow & & \\
\n& \ar[r]^{\nabla} & \\
\downarrow & \downarrow & \downarrow \\
C_{(n_0)} \times \prod C_{(n_0)} & C_{(n_0+1)} & C^{(n_0+1)} \\
\end{array}
\end{array}
\]

(here $\nabla$ is the diagonal morphism). Let $\alpha : C_{(1)} \prod C_{(1)} \to C_{(1)}$ be the cokernel of the diagonal morphism $\nabla : C_{(1)} \to C_{(1)} \prod C_{(1)}$. Clearly, $\nabla$ and $\alpha$ are, resp., strict monomorphism and strict epimorphism. Set $(D_{n_0+1}, \alpha_1) = \operatorname{Coker}((i_1 \prod i'_1) \circ \nabla)$ and $(D_{n_0}, \alpha_0) = \operatorname{Coker}((i \prod i) \circ \nabla)$. Applying $\alpha_\ast$ to diagram (A.7) obtain the two lower rows of the following diagram

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{
0 & C^{(1)} & D_0 & C^{(1)} & 0 \\
\downarrow & \downarrow \downarrow & \downarrow s & \downarrow f_{n_0+1} & \downarrow \downarrow \\
0 & C^{(1)} & D_{n_0+1} & C^{(n_0)} & 0 \\
\downarrow & \downarrow \downarrow & \downarrow u & \downarrow i_{n_0-1,n_0} & \downarrow \downarrow \\
0 & C^{(1)} & D_{n_0} & C^{(n_0-1)} & 0 \\
\end{array}
\end{array}
\]

Note that the middle line of this diagram equals $\varepsilon_{n_0+1} - \varepsilon'_{n_0+1} \in \operatorname{Ext}(C_{(n_0)}, C^{(1)})$, and at the third row we have a trivial extension. This implies the existence of the first row of our diagram. As it was pointed out earlier, a splitting of the third line can be done via the morphism $f$ from the commutative diagram

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{
C_{(n_0)} \times \prod C_{(n_0-1)} & C^{(n_0)} \\
\downarrow & \downarrow \\
C^{(1)} & D_{n_0} \\
\end{array}
\end{array}
\]

(Notice that the morphism $s : D_{n_0+1} \to D_0$ is the cokernel of the composition $\ker f \to D_{n_0} \to D_{n_0+1}$.)

Above diagram (A.8) means that the morphism of multiplication by $p$ on $C_{(n_0+1)} \prod C_{(n_0)}$ factors through the diagonal embedding of $C_{(n_0)}$ into $C^{(n_0)} \prod C_{(n_0-1)}$. From diagram (A.10) it follows that $p \id_{D_{n_0+1}}$ factors through the embedding $\ker f \to D_{n_0} \to D_{n_0+1}$. Therefore, $pD_0 = 0$ i.e. the first line in diagram (A.9) is an element of the trivial group $\operatorname{Ext}_S(C^{(1)}, C^{(1)}) = 0$. So, the second row in (A.9) is a trivial extension, i.e. the extensions $\varepsilon_{n_0+1}$ and $\varepsilon'_{n_0+1}$ from diagrams (A.5) and (A.6) are equivalent. This implies the existence of isomorphism $f_{n_0+1}$.

\[\square\]

A.2.3. Splitting of extensions of $p$-divisible groups.
Theorem A.5. Suppose \((C^{(n)}, i^{(n)})_{n \geq 0}\) is a \(p\)-divisible group in the category \(\mathcal{S}\) and there are \(D_1, D_2 \in \mathcal{S}_1\) such that \(C^{(1)} \in \text{Ext}_{\mathcal{S}_1}(D_2, D_1)\) and \(\text{Ext}_{\mathcal{S}_1}(D_1, D_2) = 0\). Then there is an exact sequence of \(p\)-divisible groups

\[
0 \rightarrow (C^{(n)}, i^{(n)})_{n \geq 0} \rightarrow (C^{(n)}, i^{(n)})_{n \geq 0} \rightarrow (C^{(2)}, i^{(2)})_{n \geq 0} \rightarrow 0
\]

in \(\mathcal{S}\) such that \(C^{(1)} = D_1\) and \(C^{(1)}(2) = D_2\).

Proof. We have the exact sequence \(0 \rightarrow D_1 \xrightarrow{i} C^{(1)} \xrightarrow{j} D_2 \rightarrow 0\). We must show for all \(n \geq 1\), the existence of objects \(C^{(n)}\), strict monomorphisms \(\gamma_n : C^{(n)}(n) \rightarrow C^{(n)}\) and \(i^{(n)} : C^{(n)} \rightarrow C^{(n+1)}\) such that \((C^{(n)}, i^{(n)})_{n \geq 0}\) is a \(p\)-divisible group, the system \((\gamma_n)_{n \geq 0}\) defines an embedding of this \(p\)-divisible group into the original \(p\)-divisible group \((C^{(n)}, i^{(n)})_{n \geq 0}\, C^{(1)} = D_1\) and \(\gamma_1 = i\). Agree to use for all \(0 \leq m \leq n\), the notation \(i_{mn}\) and \(j_{nm}\) from Subsection A.2.1 for the original \(p\)-divisible group and set \(C^{(n)} = C_{n0}\).

Illustrate the idea of proof by considering the case \(n = 2\). Set \(C_{11} = D_1\) and consider the following commutative diagram with exact rows \(\varepsilon_2\) and \(\varepsilon^{(1)}_2 = i^*\varepsilon_2\):

\[
\begin{array}{c}
\varepsilon_2 : 0 \rightarrow C_{10} \xrightarrow{i^{(2)}} C_{20} \xrightarrow{j^{(2)}} C_{10} = 0 \\
\varepsilon^{(1)}_2 : 0 \rightarrow C_{10} \xrightarrow{i^{(1)}} C_{21} \xrightarrow{j^{(1)}} C_{11} = 0 \\
\end{array}
\]

Then \(\gamma^{(1)}_2 \circ p \circ \text{id}_{C^{21}} = p \circ \text{id}_{C^{20}} \circ \gamma^{(1)}_2 = i_{12} \circ j_{21} \circ \gamma^{(1)}_2 = i_{12} \circ i_{21} \circ j_{21}\). By Lemma A.2, \(\gamma^{(1)}_2\) is (strict) monomorphism. Therefore, \(p \circ \text{id}_{C^{21}} = i_{21} \circ i_{21}\).

Then the morphism \(j : \text{Ext}_{\mathcal{S}}(C_{11}, C_{10}) \rightarrow \text{Ext}_{\mathcal{S}}(C_{11}, D_2)\) induces the following commutative diagram

\[
\begin{array}{c}
0 \rightarrow C_{10} \xrightarrow{i^{(2)}} C_{21} \xrightarrow{j^{(2)}} C_{11} = 0 \\
0 \rightarrow D_2 \xrightarrow{\alpha} D_{21} \xrightarrow{\text{id}} C_{11} = 0 \\
\end{array}
\]

Here \(p \circ \text{id}_{D^{21}} \circ f = f \circ p \circ \text{id}_{C^{21}} = f \circ i_{12} \circ j_{21} = \alpha \circ i_{21} = j_{21} = 0\). By Lemma A.1, \(f\) is (strictly) epimorphic. Therefore, \(p \circ \text{id}_{D^{21}} = 0\), i.e. \(D_{21} \in \text{Ext}_{\mathcal{S}_1}(C_{11}, D_2) = 0\). Then the exact sequence \(\text{Hom}_{\mathcal{S}} - \text{Ext}_{\mathcal{S}}\) implies the commutative diagram

\[
\begin{array}{c}
0 \rightarrow C_{10} \xrightarrow{i^{(2)}} C_{21} \xrightarrow{j^{(2)}} C_{11} = 0 \\
0 \rightarrow C_{11} \xrightarrow{i^{(2)}} C_{22} \xrightarrow{j^{(2)}} C_{11} = 0 \\
\end{array}
\]

Verify that one can set \(C^{(2)}_{1} = C_{22}\) and \(i^{(2)}_{1} = i^{(2)}_{12}\). Indeed,

\[
\gamma^{(2)}_2 \circ p \circ \text{id}_{C^{22}} = p \circ \text{id}_{C^{21}} \circ \gamma^{(2)}_2 = (i^{(1)}_{12} \circ i) \circ (j^{(1)}_{21} \circ \gamma^{(2)}_2) = \gamma^{(2)}_2 \circ i^{(2)}_{12} \circ j^{(2)}_{21}
\]
and because $\gamma_2^{(2)}$ is monomorphism (use axiom SP1), $p\text{id}_{C_{22}} = j_{22}^{(2)} \circ j_{21}$. Thus, we constructed a segment of length 2 of the $p$-divisible group $(C^{(n)}, j^{(n)})_{n \geq 0}$. Consider the general case.

**Lemma A.6.** In the category $S$ there are the following commutative diagrams with exact lines:

- For $k \geq 1$,

\[
\begin{array}{cccccccc}
E_k^1: & 0 & \to & C_{k-1,0} & \xrightarrow{i_{k-1,k}^{(0)}} & C_{k0} & \xrightarrow{j_{k1}^{(0)}} & C_{10} & \to & 0 \\
& & \downarrow{\text{id}} & & \downarrow{\gamma_k^{(1)}} & & \downarrow{i} & & \\
& 0 & \to & C_{k-1,0} & \xrightarrow{i_{k-1,k}^{(1)}} & C_{k1} & \xrightarrow{j_{k1}^{(1)}} & C_{11} & \to & 0 \\
\end{array}
\]

- For $2 \leq t \leq k$,

\[
\begin{array}{cccccccc}
E_t^1: & 0 & \to & C_{k-1,t-2} & \xrightarrow{i_{k-1,k-2}^{(t-1)}} & C_{k,t-1} & \xrightarrow{j_{k1}^{(t-1)}} & C_{11} & \to & 0 \\
& & \downarrow{\gamma_{k-1}^{(t-1)}} & & \downarrow{\gamma_k^{(t)}} & & \downarrow{\text{id}} & & \\
& 0 & \to & C_{k-1,t-1} & \xrightarrow{i_{k-1,k-1}^{(t)}} & C_{kt} & \xrightarrow{j_{k1}^{(t)}} & C_{11} & \to & 0 \\
\end{array}
\]

- For $1 \leq t < k$,

\[
\begin{array}{cccccccc}
\Delta_k^1: & 0 & \to & C_{k-1,t-1} & \xrightarrow{i_{k-1,k-1}^{(t)}} & C_{kt} & \xrightarrow{j_{k1}^{(t)}} & C_{11} & \to & 0 \\
& & \downarrow{j_{k-1,k-2}^{(t-1)}} & & \downarrow{j_{k1}^{(t)}} & & \downarrow{\text{id}} & & \\
& 0 & \to & C_{k-2,t-1} & \xrightarrow{i_{k-2,k-1}^{(t)}} & C_{k-1,t} & \xrightarrow{j_{k1}^{(t)}} & C_{11} & \to & 0 \\
\end{array}
\]

- For $1 \leq t < k$,

\[
\begin{array}{cccccccc}
\Omega_k^1: & 0 & \to & C_{kt} & \xrightarrow{\gamma_k^{(t)}} & C_{k,t-1} & \xrightarrow{f_{k}^{(t)}} & D_2 & \to & 0 \\
& & \downarrow{j_{k1}^{(0)}} & & \downarrow{j_{k1}^{(t-1)}} & & \downarrow{\text{id}} & & \\
& 0 & \to & C_{k-1,t} & \xrightarrow{\gamma_k^{(0)}} & C_{k-1,t-1} & \xrightarrow{f_{k-1}^{(0)}} & D_2 & \to & 0 \\
\end{array}
\]

where for all indices $k$, $C_{k0} = C^{(k)}$, $i_{k,k+1}^{(0)} = i^{(k)}$, $j_{k+1,k}^{(0)} = j_{k+1,1}^{(0)} = j_{k+1,k} = j_{k+1,k}$. 

**Proof.** Construct the diagram $E_k^1$ by setting $\gamma_1^{(1)} = i$, $j_{11}^{(0)} = \text{id}_{C_{10}}$, $j_{11}^{(1)} = \text{id}_{C_{11}}$. Then for any $k \geq 2$, the upper row of $E_k^1$ is the short exact sequence $\varepsilon_k \in \text{Ext}_S(C_{10}, C_{k-1,0})$ from the original $p$-divisible group $(C_{k0}, j^{(k)})_{k \geq 0}$. Then $E_k^1$ is just a standard diagram relating $\varepsilon_k$ and $i^*\varepsilon_k$. For any $k \geq 2$, we have $(j_{k,k-1} \circ \varepsilon_k = \varepsilon_{k-1}$, therefore, $(j_{k,k-1} \circ i^*\varepsilon_k = i^*\varepsilon_{k-1}$ and we obtain $\Delta_k^1$. The upper row of $\Omega_k^1$ is obtained from the middle column of $E_k^1$ because Coker $\gamma_k^{(1)} \simeq \text{Coker } i = (D_2, j)$. Similarly, the lower row of $\Omega_k^1$ is obtained from $E_{k-1}^1$. The
left square of \( \Omega^1_k \) is commutative by the definition of \( j^{(1)}_{k,k-1} \). The right square is commutative because \( \Omega^1_k \) relates diagrams \( E^1_k \) and \( E^1_{k-1} \).

Suppose now we are given integers \( k_0 \geq 2 \) and \( t_0 < k_0 \) such that the required diagrams \( E^1_k \), \( \Delta^1_k \) and \( \Omega^1_k \) have been already constructed for all \( k < k_0 \) with all relevant \( t \) and for \( k = k_0 \) with \( 1 \leq t \leq t_0 \). Clearly, all \( i^{(t)}_{k,k-1} \) and \( \gamma^{(t)}_k \) are strict monomorphisms and all \( j^{(t)}_{k,k-1} \), \( j^{(t)}_k \) and \( f^{(t)}_k \) are strict epimorphisms.

Constructing \( E^{t_0+1}_{k_0} \). Apply \((f^{(t_0)}_{k_0-1})_*\) to \( E^{t_0}_{k_0} \):

Then \( \text{Ker}(C_{k_0,t_0} \to D^*) = (C_{k_0-1,t_0}, j^{(t_0)}_{k_0-1,k_0} \circ \gamma^{(t_0)}_{k_0-1}) \). Consider the strict monomorphism \( \gamma_{k_0,t_0} := \gamma^{(1)}_0 \circ \ldots \circ \gamma^{(t_0)}_{k_0} : C_{k_0,t_0} \to C_{k_0,0} \) and its analogue \( \gamma_{k_0-1,t_0-1} : C_{k_0-1,t_0-1} \to C_{k_0-1,0} \). Because \( t_0 \neq 0 \), the diagrams \( \Omega^0_{k_0} \) and \( E^1_{k_0} \) give the commutative diagram

\[ \begin{array}{ccc}
C_{k_0,t_0} & \gamma^{(t_0)}_{k_0} & C_{k_0,0} \\
j^{(t_0)}_{k_0,k_0-1} & & \\
C_{k_0-1,t_0} & \gamma^{(t_0)}_{k_0-1} & C_{k_0-1,t_0-1} & \gamma^{(t_0)}_{k_0-1,t_0-1} & C_{k_0-1,0} \\
j^{(t_0)}_{k_0-1,k_0} & & \\
C_{k_0,t_0} & \gamma^{(t_0)}_{k_0} & C_{k_0,0} \\
\end{array} \]

Then \( p\text{id}C_{k_0,0} = i^{(0)}_{k_0-1,k_0} \circ j^{(0)}_{k_0,k_0-1} \) implies \( p\text{id}C_{k_0,t_0} = (i^{(t_0)}_{k_0-1,k_0} \circ \gamma^{(t_0)}_{k_0-1}) \circ j^{(t_0)}_{k_0,k_0-1} \), i.e. \( p\text{id}C_{k_0,t_0} \) factors through \( \text{Ker}(C_{k_0,t_0} \to D^*) \) and \( p\text{id}D^* = 0 \). Then \( \text{Ext}_S(C_{11}, D_2) = 0 \) implies \((f^{(t_0)}_{k_0-1}, \varepsilon_{k_0}) = 0 \), and 6-terms \( \text{Hom}_S - \text{Ext}_S \) exact sequence gives \( E^{t_0+1}_{k_0} \):

\[ \begin{array}{ccc}
0 & \rightarrow & C_{k_0-1,t_0-1} & \rightarrow & C_{k_0,t_0} & \rightarrow & C_{11} & \rightarrow & 0 \\
\gamma^{(t_0)}_{k_0-1} & & i^{(t_0)}_{k_0-1,k_0} & & j^{(t_0)}_{k_0,k_0-1} & & \text{id} & & \\
0 & \rightarrow & C_{k_0-1,t_0} & \rightarrow & C_{k_0,t_0+1} & \rightarrow & C_{11} & \rightarrow & 0 \\
\end{array} \]

We shall denote the rows of this diagram by \( \varepsilon^{(t_0)}_{k_0} \) and \( \varepsilon^{(t_0+1)}_{k_0} \).
Constructing $\Delta_{t_0 \to 1}^{t_0+1}$. Assume that $t_0 + 1 < k_0$. The above extension $\varepsilon_{k_0}^{(t_0+1)}$ is not uniquely defined by $\varepsilon_{k_0}^{(t_0)}$. Show that its choice can be done in such a way that the diagram $\Delta_{t_0 \to 1}^{t_0+1}$ commutes. Consider the short exact sequences from $\Omega_{k_0-1}^{t_0}$. They give rise to the following exact sequences of abelian groups, where $H := \text{Hom}(C_{t_0}, D_{t_0})$ and $E := \text{Ext}(C_{t_0}, D_{t_0})$

\[
\begin{array}{cccc}
H & \xrightarrow{\gamma_{k_0-1}^{(t_0)}} & \text{Ext}(C_{t_0}, C_{k_0-1},D_{t_0}) & \xrightarrow{id} & E \\
\downarrow & & \downarrow & & \downarrow \\
H & \xrightarrow{\gamma_{k_0-2}^{(t_0)}} & \text{Ext}(C_{t_0-1}, C_{k_0-2},D_{t_0-1}) & \xrightarrow{id} & E \\
\end{array}
\]

(A.12)

As we saw earlier, the commutativity of $E_{k_0}^{t_0+1}$ is equivalent to the following relation

\[(\gamma_{k_0-1}^{(t_0)})_* \varepsilon_{k_0}^{(t_0+1)} = \varepsilon_{k_0}^{(t_0)} \tag{A.13}\]

From $\Delta_{t_0}^{k_0}$ it follows that $\varepsilon_{k_0-1}^{(t_0)} = (\gamma_{k_0-1}^{(t_0-1)})_* \varepsilon_{k_0}^{(t_0)}$, and from $E_{k_0-1}^{t_0+1}$ it follows that $(\gamma_{k_0-2}^{(t_0)})_* \varepsilon_{k_0-1}^{(t_0+1)} = \varepsilon_{k_0-1}^{(t_0)}$. Then (A.12) implies that $\varepsilon_{k_0}^{(t_0+1)}$ from (A.13) can be chosen in such a way that $(\gamma_{k_0-1, k_0-2}^{(t_0)})_* \varepsilon_{k_0}^{(t_0+1)} = \varepsilon_{k_0-1}^{(t_0+1)}$. This gives the diagram $\Delta_{t_0}^{t_0+1}$.

Constructing $\Omega_{k_0}^{t_0+1}$. The above arguments imply that the left squares of diagrams $E_{k_0}^{t_0+1}$ and $E_{k_0-1}^{t_0}$ are related via the following commutative diagram

\[
\text{Documenta Mathematica 18 (2013) 547–619}
From diagrams $\Omega_{k0}^{t0}$, $E_{k0}^{t0+1}$ and $E_{k0}^{t0}$ it follows that the induced map $\text{Coker}\gamma_{k0}^{(t0+1)} : \text{Coker}\gamma_{k0}^{(t0)} \simeq D_2$ is isomorphism. This is equivalent to the existence of diagram $\Omega_{k0}^{t0+1}$. The lemma is proved. \hfill \Box

For any $k \geq 1$, set $C_{kk} = C_{1}^{(k)}, i_{k-1:k}^{(k)} = i_{1}^{(k)}$. Then use diagrams $E_{k}^{t}$ to define the inductive system $(C_{1}^{(k)}, i_{1}^{(k)})_{k \geq 0}$. Denote by $\gamma_{k}$ the strict monomorphism $\gamma_{k}^{(1)} \circ \ldots \circ \gamma_{k}^{(k)} : C_{1}^{(k)} \rightarrow C^{(k)}$. From diagrams $E_{k}^{t}$, $1 \leq t \leq k$, obtain the following commutative diagrams:

$$(A.14) \quad 0 \rightarrow C_{1}^{(k-1)} \overset{i_{k-1}^{(k)}}{\rightarrow} C_{1}^{(k)} \overset{\gamma_{k}}{\rightarrow} C_{1}^{(k)} \overset{\gamma_{k}}{\rightarrow} C_{1}^{(1)} \rightarrow 0$$

It remains only to prove that the inductive system $(C_{1}^{(n)}, i_{1}^{(n)})_{n \geq 0}$ is a $p$-divisible group in $S$. From diagrams $E_{k}^{t}$ and $\Delta_{k}^{k-1}$ obtain the following commutative
diagrams with exact rows

\begin{align*}
\text{(A.15)} & \quad 0 \rightarrow C_{k-1,k-1} \xrightarrow{j_{k-1,k}} C_{kk} \xrightarrow{j_{k1}} C_{11} \rightarrow 0 \\
& \quad 0 \rightarrow C_{k-2,k-2} \xrightarrow{j_{k-2,k-2}\gamma_{k-1}} C_{k-1,k-1} \xrightarrow{j_{k-1,k-1}\gamma_k} C_{11} \rightarrow 0 \\
& \quad \varepsilon_{k-2,k-2} \xrightarrow{j_{k-1,k-2}\gamma_{k-1}} C_{k-1,k-1} \xrightarrow{j_{k-1,k-1}\gamma_k} C_{11} \rightarrow 0
\end{align*}

If \( k = 3 \) then the left vertical morphism of this diagram is equal to \( j_{21}^{(1)} \circ \gamma_2^{(2)} = j_{21}^{(2)} \) and is a strict monomorphism. By induction all morphisms \( j_{k,k-1} := j_{k,k-1} \circ \gamma_k \) are strict epimorphisms and are included in the following commutative diagrams

\begin{align*}
\text{(A.16)} & \quad C^{(k)} \xrightarrow{j_{k,k-1}} C^{(k-1)} \\
& \quad C^{(k)} \xrightarrow{j_{k,k-1}} C^{(k-1)} \\
& \quad C^{(k-1)} \xrightarrow{j_{k,k-1}} C^{(k-1)}
\end{align*}

For \( 0 \leq m \leq n \), set \( \varepsilon_{nm} = \varepsilon_{m+1,m} \circ \cdots \circ \varepsilon_{n,n-1} \) and \( \varepsilon_{nm}' = \varepsilon_{n-1,n} \circ \cdots \circ \varepsilon_{m+1,m+1} \).

Composing diagrams (A.15) obtain the following commutative diagram with exact rows

\begin{align*}
0 & \rightarrow C_1^{(n-1)} \xrightarrow{\varepsilon_{n-1,n}} C_1^{(n)} \xrightarrow{j_{n1}} C_1^{(1)} \rightarrow 0 \\
& \quad 0 \rightarrow C_1^{(m-1)} \xrightarrow{\varepsilon_{m-1,m}} C_1^{(m)} \xrightarrow{j_{m1}} C_1^{(1)} \rightarrow 0 \\
& \quad 0 \rightarrow C_1^{(1)} \xrightarrow{id} C_1^{(1)} \rightarrow 0
\end{align*}

Thus, \( \varepsilon_{n-1,n} \) induces the isomorphism \( \text{Ker} \ j_{n-1,n-1} \cong \text{Ker} \ j_{nm} \). Therefore, \( \text{Ker} \ j_{nm} = (C_1^{(n-m)}, \varepsilon_{n-m,n}) \) if we prove that

\begin{align*}
\text{(A.17)} & \quad \text{Ker} \ j_{k1} = (C_1^{k-1}, \varepsilon_{k-1,k}).
\end{align*}

As we noticed earlier, \( j_{k1} = j_{21} \circ \cdots \circ j_{k,k-1} \). Therefore, diagrams (A.16) imply that \( j_{k1} \circ \gamma_k = \gamma_1 \circ j_{k1} \). Now diagram (A.14) implies that \( \gamma_1 \circ j_{k1} = \gamma_1 \circ j_{k1} \), and, therefore, \( j_{k1} = j_{k1}' \) because \( \gamma_1 \) is monomorphism. Hence equality (A.17) follows from diagram (A.14) and \((C_1^{(n)}, \varepsilon_{1}^{(n)})_{n \geq 0}\) satisfies the part a) of the definition of \( p \)-divisible groups.
From diagrams (A.14) and (A.16) one can easily obtain for all indices $0 \leq m \leq n$, the commutativity of the following diagrams:

\[
\begin{array}{ccc}
C(n) & \xrightarrow{j_{n,n-m}} & C(n-m) \\
\gamma_n & \downarrow & \downarrow \\
C_1(n) & \xrightarrow{j'_{n,n-m}} & C_1(n-m)
\end{array}
\]

\[
\begin{array}{ccc}
i_{n-m,n} & \xrightarrow{i_{n-m,n}} & i_{n-m,n} \\
\gamma_n & \downarrow & \downarrow \\
i_{n-m,n} & \xrightarrow{i'_{n-m,n}} & i_{n-m,n}
\end{array}
\]

Because $\gamma_n$ is monomorphism, the equality $i_{n-m,n} \circ j_{n,n-m} = p^m \text{id}_{C(n)}$ implies the equality $i'_{n-m,n} \circ j'_{n,n-m} = p^m \text{id}_{C_1(n)}$. This gives the part b) of the definition of $p$-divisible groups for $(C_1(n), i_{1(n)})_{n \geq 0}$. The proposition is proved. \hfill \Box

**Appendix B. SAGE program**

This program computes the class number of the field $\mathbb{Q}(\sqrt[3]{3}, \zeta_9)$ and finds the basis $f_1, f_2, \ldots, f_9$ of the 3-subgroup of units in this field such that for the normalized 3-adic valuation $v_3$ and all $1 \leq i \leq 9$, the natural numbers $a_i = 18v_3(f_i \pm 1)$ are prime to 3 and $1 \leq a_1 < a_2 < \cdots < a_9$. The result appears as the vector $af = (a_1, a_2, \ldots, a_9) = (1, 2, 4, 5, 7, 8, 10, 13, 16).

Remark. First 4 lines introduce the field $X = \mathbb{Q}(\sqrt[3]{3}, \zeta_9)$; its elements appear as polynomials in variable $d$ of degree $\leq 17$. Then we find the class number of $X$ and form the array $e = (e[1], \ldots, e[9])$ of minimal generators of the group $U/U^3$, where $U$ is the group of units in $X$. Next block gives a standard procedure to determine for any $x \in U$ the maximal natural number $p(x)$ such that $x \pm 1$ is divisible precisely by $\pi^{p(x)}$, where $\pi \in X$, $\langle \pi^{18} \rangle = (3)$. The remaining part of the program is based on a standard technique from Linear algebra to rearrange the given system of generators $e$ into a new system $f$ with required properties. As a matter of fact, we use that the class number of $X$ is prime to 3 (it equals 1) by allowing $k < 5$ on line 21. (Any unit $x \equiv 1 \mod \pi^{2k}$ is a cube in the 3-completion of $X$ by Hensel’s Lemma and, therefore, is a cube in $X$.) The last two lines contain the values of the class number of $X$ and the exponents $(a(f[1]), \ldots, a(f[9]))$.

NEKOVÁŘ DUALITY OVER \( p \)-ADIC LIE EXTENSIONS OF GLOBAL FIELDS

MENG FAI LIM AND ROMYAR T. SHARIFI

Received: July 12, 2012
Revised: March 11, 2013

Communicated by Peter Schneider

Abstract. Tate duality is a Pontryagin duality between the \( i \)th Galois cohomology group of the absolute Galois group of a local field with coefficients in a finite module and the \((2 - i)\)th cohomology group of the Tate twist of the Pontryagin dual of the module. Poitou-Tate duality has a similar formulation, but the duality now takes place between Galois cohomology groups of a global field with restricted ramification and compactly-supported cohomology groups. Nekovář proved analogues of these in which the module in question is a finitely generated module \( T \) over a complete commutative local Noetherian ring \( R \) with a commuting Galois action, or a bounded complex thereof, and the Pontryagin dual is replaced with the Grothendieck dual \( T^* \), which is a bounded complex of the same form. The cochain complexes computing the Galois cohomology groups of \( T \) and \( T^*(1) \) are then Grothendieck dual to each other in the derived category of finitely generated \( R \)-modules. Given a \( p \)-adic Lie extension of the ground field, we extend these to dualities between Galois cochain complexes of induced modules of \( T \) and \( T^*(1) \) in the derived category of finitely generated modules over the possibly noncommutative Iwasawa algebra with \( R \)-coefficients.

Keywords and Phrases: Galois cohomology, Tate duality, Poitou-Tate duality, Grothendieck duality
1 Introduction

1.1 Duality

In [Nek], Nekovár gave formulations of analogues of Tate and Poitou-Tate duality for finitely generated modules over a complete commutative local Noetherian ring $R$ with finite residue field of characteristic a fixed prime $p$. In the usual formulation of these dualities, one takes the Pontryagin dual, which does not in general preserve the property of finite generation. Nekovár takes the dual with respect to a dualizing complex of Grothendieck so as to have a duality between bounded complexes of $R$-modules with finitely generated cohomology groups. This paper is devoted to a generalization of this result to the setting of nonabelian $p$-adic Lie extensions.

Recall that a dualizing complex $\omega_R$ is a bounded complex of $R$-modules with cohomology finitely generated over $R$ that has the property that for every complex $M$ of finitely generated $R$-modules, the Grothendieck dual $R\text{Hom}_R(M, \omega_R)$ in the derived category of $R$-modules $D(\text{Mod}_R)$ has finitely generated cohomology, and moreover, the canonical morphism

$$M \longrightarrow R\text{Hom}_R(R\text{Hom}_R(M, \omega_R), \omega_R)$$

is an isomorphism in $D(\text{Mod}_R)$. Such a complex exists and is unique up to quasi-isomorphism and translation (see [Har1]).

One can choose $\omega_R$ to be a bounded complex of injectives, in which case the derived homomorphism complexes are represented by the complexes of homomorphisms themselves. If $R$ is regular, then $R$ itself, as a complex concentrated in degree 0, is a dualizing complex, but $R$ is not in general $R$-injective. If $R = \mathbb{Z}_p$, for instance, then the complex $[\mathbb{Q}_p \rightarrow \mathbb{Q}_p/\mathbb{Z}_p]$ concentrated in degrees 0 and 1 provides a complex of injective $\mathbb{Z}_p$-modules quasi-isomorphic to $\mathbb{Z}_p$.

Let us explain Nekovár’s theorem, and our generalization of it, in the setting of Poitou-Tate duality. Let $F$ be a global field with characteristic not equal to $p$. Let $S$ be a finite set of primes of $F$ that, if $F$ is a number field, contains all primes over $p$ and any real places, and let $G_{F,S}$ denote the Galois group of the maximal unramified outside $S$ extension of $F$. We remark that a finitely generated $R$-module has a canonical topology arising from its filtration by powers of the maximal ideal of $R$. Let $T$ be a bounded complex in the category of finitely generated (topological) $R$-modules with $R$-linear continuous $G_{F,S}$-actions. We use $R\Gamma(G_{F,S}, T)$ to denote the object in $D(\text{Mod}_R)$ corresponding to the complex of continuous $G_{F,S}$-cochains with coefficients in $T$, and we use $R\Gamma_{(c)}(G_{F,S}, T)$ to denote the derived object attached to the complex of continuous compactly supported cochains (using Tate groups for real places in its definition as a cone: see Section [4]).

There exists a bounded complex $T^*$ of finitely generated $R$-modules with $R$-linear continuous $G_{F,S}$-actions that represents $R\text{Hom}_R(T, \omega_R)$ in the derived category of such modules. Nekovár’s duality theorem is then as follows (see Documenta Mathematica 18 (2013) 621–678).
Theorem (Nekovář). We have an isomorphism
\[ R\Gamma(G_{F,S}, T) \to R\text{Hom}_R \left( R\Gamma_{(c)}(G_{F,S}, T^*(1)), \omega_R \right)[-3] \]
in the derived category of finitely generated \( R \)-modules.

In this paper, we consider a generalization of this to the setting of noncommutative Iwasawa theory. Suppose that \( F_\infty \) is a \( p \)-adic Lie extension of \( F \) contained in \( F_S \). We denote by \( \Gamma \) the Galois group of the extension \( F_\infty/F \), and we let \( \Lambda = R[\Gamma] \) denote the resulting Iwasawa algebra over \( R \). For a finitely generated \( R \)-module \( T \) with a continuous \( R \)-linear \( G_{F,S} \)-action, we define a finitely generated \( \Lambda \)-module \( F\Gamma(T) \) with a continuous \( \Lambda \)-linear \( G_{F,S} \)-action by
\[ F\Gamma(T) = \Lambda^\iota \otimes_R T, \]
where the superscript \( \iota \) denotes that an element of \( \Gamma \) in \( \Lambda \) acts here on \( \Lambda \) by right multiplication by its inverse, and where \( G_{F,S} \) acts on \( \Lambda \) through the quotient map \( G_{F,S} \to \Gamma \) by left multiplication and then diagonally on the tensor product.

The \( G_{F,S} \)-cohomology of \( F\Gamma(T) \) is interesting in that a version of Shapiro’s lemma provides natural isomorphisms of continuous cohomology groups
\[ H^n(G_{F,S}, F\Gamma(T)) \cong \varprojlim H^n(G_{F_\alpha,S}, T) \]
for every \( n \geq 0 \), where the limit is taken over \( \alpha \) indexing the finite Galois extensions \( F_\alpha \) of \( F \) that are contained in \( F_\infty \) (cf. [Lim2, Lemma 5.3.1]). That is, the cohomology groups of \( F\Gamma(T) \) are the Iwasawa cohomology groups of the module \( T \) itself for the extension \( F_\infty/F \), and this identification is one of \( \Lambda \)-modules. We also have the analogous statements for compactly supported cohomology, as seen in [Lim2, Proposition 5.3.3]. Therefore, we can reduce the question of finding dualities among Iwasawa cohomology groups of compact modules to that of obtaining dualities among cohomology groups for \( G_{F,S} \) itself. Note that, however, it is not even a priori clear in this setting that \( H^n(G_{F,S}, F\Gamma(T)) \) is a finitely generated \( \Lambda \)-module, let alone that we can find such a duality of \( \Lambda \)-modules.

The following is our main theorem (cf. Theorem 4.5.1).

Theorem. We have isomorphisms
\[ R\Gamma(G_{F,S}, F\Gamma(T)) \to R\text{Hom}_{\Lambda^\iota} \left( R\Gamma_{(c)}(G_{F,S}, F\Gamma(T^*(1)), \Lambda \otimes_R \omega_R \right)[-3] \]
\[ R\Gamma_{(c)}(G_{F,S}, F\Gamma(T)) \to R\text{Hom}_{\Lambda^\iota} \left( R\Gamma(G_{F,S}, F\Gamma(T^*(1)), \Lambda \otimes_R \omega_R \right)[-3] \]
in the derived category of finitely generated \( \Lambda \)-modules.

\footnote{Actually, Nekovář’s longer treatise is particularly concerned with a generalization of this duality that takes place between Selmer complexes, which we do not address in this article.}
Nekovář proves the above theorem in the case that \( \Gamma \) is abelian [Nek] Theorem 8.5.6. In fact, in that case, it is an almost immediate consequence of his above-mentioned theorem. That is, suppose for instance that \( \Gamma \cong \mathbb{Z}_p^r \) for some \( r \geq 1 \). Then \( \Lambda \) is a complete commutative Noetherian local ring with finite residue field of characteristic \( p \). Moreover, its dualizing complex is isomorphic to \( \Lambda \otimes_R \omega_R \) in the derived category of \( \Lambda \)-modules [Nek] Lemma 8.4.5.6. Therefore, the commutative theory described above applies to \( \Lambda \), and Nekovář is able to deduce the result from this. On the other hand, since we are working with nonabelian \( \Gamma \) and hence noncommutative \( \Lambda \), we do not know that there exists a (nice enough) dualizing complex, and so the proof of our main theorem takes a different route. The idea is a simple one, though the proof is rather involved: after reducing to the case that \( R \) is regular and \( \mathbb{Z}_p \)-flat, we perform an inductive argument, using the grading on \( \Lambda \) arising from the powers of its augmentation ideal, to deduce our result from Nekovář’s.

We remark that, in their manuscript on the noncommutative main conjecture, Fukaya and Kato stated an analogue of our main theorem, with \( \Lambda \) replacing \( \Lambda \otimes_R \omega_R \) [FK1, (1.6.12)], which in turn generalized a result of Burns and Flach [BF, Lemma 12(b)] for a narrower class of rings. The result of Fukaya-Kato applies to a more general class of (adic) rings \( \Lambda \) than ours and replaces \( \mathcal{F}_T(T) \) and \( \mathcal{F}_T(T^*) \) by a bounded complex of \( \Lambda[\mathbf{G}_F,\mathcal{S}] \)-modules \( X \) and its \( \Lambda \)-dual \( \text{Hom}_\Lambda(X, \Lambda) \). However, in order to be able to work with the \( \Lambda \)-dual, they assume that \( X \) consists of (finitely generated) projective \( \Lambda \)-modules. In the case of Iwasawa cohomology that we study, the complex \( T \) need not be quasi-isomorphic to a bounded complex of \( R[\mathbf{G}_F] \)-modules that are projective and finitely generated over \( R \). Moreover, if \( R \) is Gorenstein, then \( R \) serves as an \( R \)-dualizing complex, and our result reduces to a duality with respect to \( \Lambda \) itself, as in the result of Fukaya-Kato. We also note that Vauclair proved a noncommutative duality theorem for induced modules in the case that \( R = \mathbb{Z}_p \) and \( T \) is \( \mathbb{Z}_p \)-free, via a rather different method [Vau, Theorem 6.4].

1.2 An application

Since applications of our main result are not discussed in the body of this paper, we end the introduction with an indication of one setting in which our results naturally apply. Fix \( N \geq 1 \) not divisible by \( p \), and suppose that \( p \geq 5 \). Let \( \mathbb{Z}_{p,N} \) denote the inverse limit of the rings \( \mathbb{Z}/Np^r\mathbb{Z} \) over \( r \geq 1 \). Hida’s ordinary cuspidal \( \mathbb{Z}_p \)-Hecke algebra \( \mathfrak{h} \) of level \( Np^\infty \) is a direct product of local rings that is free of finite rank over the subalgebra \( \Omega = \mathbb{Z}_p[1 + p\mathbb{Z}_p] \) of the algebra \( \mathbb{Z}_p[[\mathbb{Z}_p,N]/\langle -1 \rangle] \) of diamond operators in \( \mathfrak{h} \) [Hid, Theorem 3.1]. Hida showed that the \( \mathfrak{h} \)-module \( \mathcal{S} \) of \( \Omega \)-adic cusp forms is \( \Omega \)-dual to \( \mathfrak{h} \) (see Ohi1 Theorem 2.5.3) for a proof), from which it follows that \( \mathcal{S} \) is a dualizing complex for \( \mathfrak{h} \).

The inverse limit

\[
\mathcal{H} = \lim_{\rightarrow} H^1_{\text{ét}}(X(Np^r)/\mathbb{Q}, \mathbb{Z}_p(1))^{\text{ord}}
\]
of ordinary parts of étale cohomology groups of modular curves is an \( \mathfrak{h}[G_{Q,S}] \)-module for the dual action of \( \mathfrak{h} \), where \( S \) is the set of primes dividing \( Np\infty \). As an \( \mathfrak{h} \)-module, Ohta showed in \([\text{Oht}2]\) that \( \mathcal{H} \) is an extension of \( S \) by \( \mathfrak{h} \). Since \( \mathfrak{h} \) is not always Gorenstein (in Eisenstein components: see \([\text{Oht}3]\) Corollary 4.2.13 for conditions), it is not at all clear that \( \mathcal{H} \) is quasi-isomorphic to a bounded complex of \( \mathfrak{h}[G_{Q,S}] \)-modules that are finitely generated and projective over \( \mathfrak{h} \), precluding the use of the duality result of Fukaya-Kato. On the other hand, there is a perfect, \( \mathfrak{h} \)-bilinear pairing \( \mathcal{H} \times \mathcal{H} \rightarrow S(1) \) which is \( G_{Q,S} \)-equivariant for the action of \( \sigma \in G_{Q,S} \) on \( S \) via the diamond operator \((\chi(\sigma))\), where \( \chi: G_{Q,S} \rightarrow \mathbb{Z}_{p,N}^\times \) is the cyclotomic character (see \([\text{FK}2]\) Section 1.6], where it is quickly derived from a pairing of Ohta’s \([\text{Oht}1]\) Definition 4.1.17]). Now fix a \( p \)-adic Lie extension \( F_\infty \) of \( \mathbb{Q} \) that is unramified outside \( S \) and contains \( \mathbb{Q}(\mu_{Np\infty}) \), and set \( \Gamma = \text{Gal}(F_\infty/\mathbb{Q}) \). The complex \( \text{R} \Gamma(\sigma;G_{Q,S},\mathcal{F}_T(\mathcal{H})) \) is the subject of the noncommutative Tamagawa number conjecture of Fukaya and Kato for \( \mathcal{H} \) (though to be precise, said conjecture is only formulated in the case that \( \mathcal{H} \) is \( \mathfrak{h} \)-projective), which is directly related to the noncommutative main conjecture for ordinary \( \Omega \)-adic cusp forms (see \([\text{FK}1]\) Sections 2.3 and 4.2)). It is also perhaps worth remarking that, in the commutative setting, the first Iwasawa cohomology group \( H^1(G_{Q,S},\mathcal{F}_T(\mathcal{H})) \) contains zeta elements constructed out of Kato’s Euler system (see \([\text{Kat}\] Section 12) or \([\text{FK}2]\) Section 3.2).

For a finitely generated \( \Lambda = \mathfrak{h}[\Gamma] \)-module \( A \), let us use \( A(\chi) \) to denote the \( \Lambda \)-module that is \( A \) as an \( \mathfrak{h} \)-module but for which the original \( \mathfrak{h} \)-linear action of \( \gamma \in \Gamma \) on \( A \) has been twisted by multiplication by the diamond operator \((\chi(\gamma))\), for any lift \( \tilde{\gamma} \in G_{Q,S} \) of \( \gamma \). Using the pairing on \( \mathcal{H} \), our main result can be seen to yield two interesting isomorphisms in the derived category of finitely generated modules over, including

\[
\text{R} \Gamma(\sigma;G_{Q,S},\mathcal{F}_T(\mathcal{H})) \longrightarrow \text{R} \text{Hom}_{\Lambda^+}(\text{R} \Gamma(\sigma;G_{Q,S},\mathcal{F}_T(\mathcal{H})),\Lambda \otimes^L \mathcal{S})(\chi)[-3].
\]

Perhaps more concretely, we have a spectral sequence

\[
\text{Ext}_{\Lambda^+}^i \left( H^{j-1}(G_{Q,S},\mathcal{F}_T(\mathcal{H})),\Lambda \otimes^L \mathcal{S} \right)(\chi) \Rightarrow H^{i+j}(\sigma;G_{Q,S},\mathcal{F}_T(\mathcal{H})).
\]

We remark that one has a similar result with \( X_1(Np^r) \) replaced by \( Y_1(Np^r) \); in this case, the pairing on \( \mathcal{H} \) to \( \mathcal{S} \) is replaced by a pairing between ordinary parts of cohomology and compactly supported cohomology groups to ordinary \( \Omega \)-adic modular forms. We also note that Fouquet has constructed an analogue of Ohta’s pairing for towers of Shimura curves attached to indefinite quaternion algebras over totally real fields \([\text{Fou}\] Proposition 2.8], providing a related setting for an application of our main result.

Acknowledgments. The material presented in this article forms a revised and extended version of the part of the Ph.D. thesis \([\text{Lim1}\] of the first author that was a collaboration between the two authors. The results of the rest of the thesis can be found in the article \([\text{Lim2}\]. The first author would like to
thank Manfred Kolster for his encouragement. The second author would like to thank Takako Fukaya, Uwe Jannsen, Jan Nekovář, Otmar Venjakob, and Amnon Yekutieli for helpful discussions. He was supported by NSF Grant DMS-0901526, and his work was partially conducted during visits to the Newton Institute in 2009 and IHES in 2010. The authors also thank the anonymous referee for pointing out a mistake in an earlier version of this work.

2 Preliminaries

In this section, we lay out some facts regarding modules over profinite rings that we shall require later in the paper. Elsewhere in the paper, we use some of the standard terminology and conventions regarding complexes, cones, shifts, total complexes of homomorphisms and tensor products, and derived categories, as can be found in [Nek], or in [Lim2] off of which this paper builds. In particular, all sign conventions will be as in the latter two papers. For further background on derived categories, we suggest the excellent book [Wei], as well as the more advanced text [KS].

2.1 Tensor products and homomorphism groups

In this subsection, $R$ is a commutative ring. By an $R$-algebra, we will mean a ring with a given homomorphism from $R$ to its center. In this section, we construct derived bifunctors of homomorphism groups and tensor products for bimodules over $R$-algebras and study a few isomorphisms that result from these constructions.

We use $\Lambda^\circ$ to denote the opposite ring to an $R$-algebra $\Lambda$. Given two $R$-algebras $\Lambda$ and $\Sigma$, we are interested in a subclass of the class of $\Lambda$-$\Sigma$-bimodules, namely, the class of $\Lambda$-$\Sigma$-bimodules with the extra property that the left $R$-action coincides with the right $R$-action. We can (and shall) identify the category of such $\Lambda$-$\Sigma$-bimodules with the category of $\Lambda \otimes_R \Sigma^\circ$-modules, and there are natural exact forgetful functors

$$\text{res}_\Lambda : \text{Mod}_{\Lambda \otimes_R \Sigma^\circ} \longrightarrow \text{Mod}_\Lambda \quad \text{and} \quad \text{res}_\Sigma^\circ : \text{Mod}_{\Lambda \otimes_R \Sigma^\circ} \longrightarrow \text{Mod}_{\Sigma^\circ},$$

which extend to exact functors on the derived categories. One observes that the categories $\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}$ and $\text{Mod}_\Lambda$ are equivalent, as are $\text{Mod}_{R \otimes_R \Sigma^\circ}$ and $\text{Mod}_{\Sigma^\circ}$.

We have following lemma, which extends [Yek Lemma 2.1].

**Lemma 2.1.1.**

(a) If $\Sigma$ is a projective (resp., flat) $R$-algebra, then $\text{res}_\Lambda$ preserves projective (resp., flat) modules. Similarly, if $\Lambda$ is a projective (resp., flat) $R$-algebra, then $\text{res}_\Sigma^\circ$ preserves projective (resp., flat) modules.

(b) If $\Sigma$ is a flat $R$-algebra, then $\text{res}_\Lambda$ preserves injectives. Similarly, if $\Lambda$ is a flat $R$-algebra, then $\text{res}_\Sigma^\circ$ preserves injectives.
Proof. (a) We prove the statements of the first sentence, those of the second being a consequence. Suppose that $\Sigma$ is a projective $R$-algebra. Since projective modules are the summands of free modules, it suffices to show that $\Lambda \otimes_R \Sigma^\circ$ is a projective $\Lambda$-module. Since $\Sigma$ is a central $R$-algebra, we have $\Sigma \cong \Sigma^\circ$ as $R$-modules. Therefore, we have $\Sigma^\circ \oplus P \cong L$ for some projective $R$-module $P$ and free $R$-module $L$. Then $\Lambda \otimes_R \Sigma^\circ$ is a direct summand of $\Lambda \otimes_R L$, which is a free $\Lambda$-module. Hence, $\Lambda \otimes_R \Sigma^\circ$ is a projective $\Lambda$-module.

Now suppose that $\Sigma$ is flat over $R$. Since flat modules are direct limits of finitely generated free modules (see [Lam, Theorem 4.34]) and tensor products preserve direct limits, it suffices to show that $\Lambda \otimes_R \Sigma^\circ$ is a flat $\Lambda$-algebra. Since $\Sigma$ is flat over $R$, we have that $\Sigma$ is a direct limit of finitely generated free $R$-modules, which implies that $\Lambda \otimes_R \Sigma^\circ$ is a direct limit of finitely generated free $\Lambda$-modules.

(b) We shall prove this for $\mathrm{res}_\Lambda$, the case of $\mathrm{res}_\Sigma^\circ$ being a consequence. The functor from $\mathrm{Mod}_\Lambda$ to $\mathrm{Mod}_{\Lambda \otimes_R \Sigma^\circ}$ sending $M$ to $M \otimes_R \Sigma^\circ$ is exact by our assumption and is left adjoint to the functor $\mathrm{res}_\Lambda$. The conclusion then follows from [Wei, Prop. 2.3.10].

Let us briefly introduce the notions of q-projective and q-injective complexes of $\Lambda$-modules and several facts regarding them arising from the work of Spaltenstein, as can be found in [Spa, Kel, Lip, Section 2.3], and [KS, Chapter 14]. A complex $P$ of $\Lambda$-modules is called q-projective if for every map $g: P \to B$ and quasi-isomorphism $s: A \to B$ of complexes of $\Lambda$-modules, there exists a map $f: P \to A$ of complexes of $\Lambda$-modules such that $g$ and $s \circ f$ are homotopy equivalent. We remark that $P$ is q-projective if and only if it is homotopy equivalent to a direct limit of bounded above complexes $P_n$ of projective $\Lambda$-modules via maps $t_n: P_n \to P_{n+1}$ that are split injective in each degree with quotients $P_{n+1}/t_n(P_n)$ having zero differentials. In particular, bounded above complexes of projectives are q-projective. If $A$ is a complex of $\Lambda$-modules, then there exists a quasi-isomorphism $P \to A$ with $P$ q-projective.

We also have the dual notion of q-injective complexes. A complex $I$ of $\Lambda$-modules is q-injective if for every map $f: A \to I$ and quasi-isomorphism $s: A \to B$ of complexes of $\Lambda$-modules, there exists a map $g: B \to I$ such that $f$ and $g \circ s$ are homotopy equivalent. A complex $I$ of $\Lambda$-modules is q-injective if and only if it is homotopy equivalent to an inverse limit of bounded below complexes $I_n$ of injective $\Lambda$-modules via maps $\pi_n: I_{n+1} \to I_n$ that are split surjective in each degree with kernels $\ker \pi_n$ having zero differentials. In particular, bounded below complexes of injectives are q-injective. If $A$ is a complex of $\Lambda$-modules, then there exists a quasi-isomorphism $A \to I$ with $I$ q-injective.

In addition to $\Lambda$ and $\Sigma$, we now let $\Omega$ be an $R$-algebra. If $A$ is a $\Lambda \otimes_R \Omega^\circ$-module and $B$ is a $\Lambda \otimes_R \Sigma^\circ$-module, we give $\mathrm{Hom}_\Lambda(A, B)$ the structure of an $\Omega \otimes_R \Sigma^\circ$-module via the left $\Omega$ and right $\Sigma$-actions

$$(\omega \cdot f)(a) = f(\omega a) \quad \text{and} \quad (f \cdot \sigma)(a) = f(a)\sigma$$
for $f \in \text{Hom}_A(A, B)$, $a \in A$, $\omega \in \Omega$, and $\sigma \in \Sigma$.

Moreover, if $A$ is a complex of $\Lambda \otimes_R \Omega^\circ$-modules and $B$ is a complex of $\Lambda \otimes_R \Sigma^\circ$-modules, we define a complex $\text{Hom}_A(A, B)$ of $\Omega \otimes_R \Sigma^\circ$-modules by

$$\text{Hom}_A^\Lambda(A, B) = \prod_{i \in \mathbb{Z}} \text{Hom}_\Lambda(A^i, B^{i+n}),$$

with the usual differentials, as in [Lim2, Section 2].

**Proposition 2.1.2.** Let $A$ be a complex of $\Lambda \otimes_R \Omega^\circ$-modules, and let $B$ be a complex of $\Lambda \otimes_R \Sigma^\circ$-modules. If $\Omega$ is a projective $R$-algebra or $\Sigma$ is a flat $R$-algebra, then we have a derived bifunctor

$$\mathbf{R}\text{Hom}_\Lambda(-, -) : \mathbf{D}(\text{Mod}_{\Lambda \otimes_R \Omega^\circ}) \to \mathbf{D}(\text{Mod}_{\Omega \otimes_R \Sigma^\circ}),$$

and $\text{Hom}_A(A, B)$ represents $\mathbf{R}\text{Hom}_\Lambda(A, B)$ if $A$ is $\pi$-projective as a complex of $\Lambda$-modules and $\Omega$ is $R$-projective or $B$ is $\pi$-injective as a complex of $\Lambda$-modules and $\Sigma$ is $R$-flat.

**Proof.** Let us first assume that $\Omega$ is a projective $R$-algebra. Since every complex of $\Lambda \otimes_R \Omega^\circ$-modules is quasi-isomorphic to a $\pi$-projective complex of $\Lambda \otimes_R \Omega^\circ$-modules, we have a derived functor

$$\mathbf{R}\text{Hom}_\Lambda(-, B) : \mathbf{D}(\text{Mod}_{\Lambda \otimes_R \Omega^\circ}) \to \mathbf{D}(\text{Mod}_{\Omega \otimes_R \Sigma^\circ}).$$

(see [Lim, Corollary 2.3.2.3]). Suppose that $f : B \to B'$ is a quasi-isomorphism of complexes of $\Lambda \otimes_R \Omega^\circ$-modules. Let $\varepsilon : P \to A$ be a quasi-isomorphism of complexes of $\Lambda \otimes_R \Omega^\circ$-modules, where $P$ is $\pi$-projective. Then $\mathbf{R}\text{Hom}_\Lambda(P, B)$ (resp., $\mathbf{R}\text{Hom}_\Lambda(P, B')$) is represented by $\text{Hom}_\Lambda(P, B)$ (resp., $\text{Hom}_\Lambda(P, B')$).

Applying Lemma 2.1.1(a), we see that $P$ is also a $\pi$-projective complex of $\Lambda$-modules, so by [Lim, Proposition 2.3.8], the induced map

$$f_* : \text{Hom}_\Lambda(P, B) \to \text{Hom}_\Lambda(P, B')$$

is a quasi-isomorphism of complexes of abelian groups. Since $f_*$ is a morphism of complexes of $\Omega \otimes_R \Sigma^\circ$-modules, it is a quasi-isomorphism of such complexes. Hence, $f$ induces isomorphisms

$$\mathbf{R}\text{Hom}_\Lambda(A, B) \to \mathbf{R}\text{Hom}_\Lambda(A, B'),$$

proving the existence of the derived bifunctor. Moreover, if $A$ is $\pi$-projective as a complex of $\Lambda$-modules, then

$$\varepsilon_* : \text{Hom}_\Lambda(A, B) \to \text{Hom}_\Lambda(P, B)$$

is a quasi-isomorphism of complexes of $\Sigma^\circ$-modules, hence of $\Omega \otimes_R \Sigma^\circ$-modules as well. Thus, $\text{Hom}_\Lambda(A, B)$ represents $\mathbf{R}\text{Hom}_\Lambda(A, B)$, as desired.

If $\Sigma$ is $R$-flat, the argument for the existence of the derived bifunctor and its computation by $\text{Hom}_\Lambda(A, B)$ in the case that $B$ is $\pi$-injective as a complex of
\(\Lambda\)-modules is the direct analogue of the above argument, employing Lemma 2.1.1(b). To see that the resulting derived functor agrees with that constructed above in the case that both \(\Omega\) is \(R\)-projective and \(\Sigma\) is \(R\)-flat, consider a quasi-isomorphism \(\varepsilon: P \to A\) as above and a quasi-isomorphism \(\delta: B \to I\) with \(I\) a \(q\)-injective complex of \(\Lambda \otimes_R \Sigma^o\)-modules. As we have quasi-isomorphisms

\[
\hom\Lambda(P, B) \xrightarrow{\delta_*} \hom\Lambda(P, I) \xleftarrow{\varepsilon_*} \hom\Lambda(A, I)
\]

of complexes of \(\Omega \otimes_R \Sigma^o\)-modules, the derived functors coincide.

Note that one always has a map \(\hom\Lambda(A, B) \to R\hom\Lambda(A, B)\) (canonical up to isomorphism in the derived category), induced either by a quasi-isomorphism \(P \to A\) with \(P\) \(q\)-projective or a quasi-isomorphism \(B \to I\) with \(I\) \(q\)-injective.

**Corollary 2.1.3.** If \(\Omega\) is a projective \(R\)-algebra, then we have a commutative diagram

\[
\begin{array}{ccc}
D(\text{Mod}_{\Lambda \otimes R \Omega})^o \times D(\text{Mod}_{\Lambda \otimes R \Sigma^o}) & \xrightarrow{R\hom\Lambda(-,-)} & D(\text{Mod}_{\Omega \otimes R \Sigma^o}) \\
\text{res_A} \times \text{id} & & \text{res_{\Sigma^o}}
\end{array}
\]

In the case that \(\Sigma\) is a flat \(R\)-algebra, we have a commutative diagram

\[
\begin{array}{ccc}
D(\text{Mod}_{\Lambda \otimes R \Omega})^o \times D(\text{Mod}_{\Lambda \otimes R \Sigma^o}) & \xrightarrow{R\hom\Lambda(-,-)} & D(\text{Mod}_{\Omega \otimes R \Sigma^o}) \\
\text{id} \times \text{res}_A & & \text{res}_I
\end{array}
\]

If \(A\) is a complex of \(\Omega \otimes_R \Lambda^o\)-modules and \(B\) is a complex of \(\Lambda \otimes_R \Sigma^o\)-modules, we define a complex \(A \otimes_{\Lambda} B\) of \(\Omega \otimes_R \Sigma^o\)-modules by

\[
(A \otimes_{\Lambda} B)^n = \bigoplus_{i \in \mathbb{Z}} A^i \otimes_{\Lambda} B^{n-i},
\]

again with the usual differentials, as in [Lim2, Section 2].

We also have a notion of a \(q\)-flat complex of \(\Lambda^o\)-modules (see [Lip, Section 2.5] and [Spa, Section 5] in the case of commutative rings, the proofs being identical); that is, a complex of \(\Lambda^o\)-modules \(A\) is said to be \(q\)-flat if for every quasi-isomorphism \(B \to C\) of complexes of \(\Lambda\)-modules, the resulting map \(A \otimes_{\Lambda} B \to C\) is also a quasi-isomorphism. In particular, \(q\)-projective complexes of \(\Lambda^o\)-modules are \(q\)-flat, any bounded above complex of flat \(\Lambda^o\)-modules is \(q\)-flat, and any filtered direct limit of \(q\)-flat complexes is \(q\)-flat. As in the case of homomorphism complexes, the total tensor product induces derived bifunctors as follows. We omit the analogous proof.
Proposition 2.1.4. Let \( A \) and \( B \) be complexes of \( \Omega \otimes_R \Lambda^\circ \)-modules and \( \Lambda \otimes_R \Sigma^\circ \)-modules, respectively. If either \( \Omega \) or \( \Sigma \) is a flat \( R \)-algebra, then we have a derived bifunctor

\[
\bigodot_k : D(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}) \times D(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}) \to D(\text{Mod}_{\Omega \otimes_R \Sigma^\circ}),
\]

and \( A \otimes \Lambda B \) represents \( A \otimes_k \Lambda B \) if \( A \) is \( q \)-flat as a complex of \( \Lambda^\circ \)-modules and \( \Omega \) is \( R \)-flat or if \( B \) is \( q \)-flat as a complex of \( \Lambda \)-modules and \( \Sigma \) is \( R \)-flat.

Proposition 2.1.4 has the following direct corollary.

Corollary 2.1.5. If \( \Omega \) is a flat \( R \)-algebra, then we have a commutative diagram

\[
\begin{array}{ccc}
D(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}) \times D(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}) & \to & D(\text{Mod}_{\Omega \otimes_R \Sigma^\circ}) \\
\text{id} \times \text{res}_{\Lambda^\circ} & & \text{res}_{\Sigma^\circ} \\
\text{res}_{\Lambda^\circ} \times \text{id} & & \\
D(\text{Mod}_{\Lambda^\circ}) \times D(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}) & \to & D(\text{Mod}_{\Sigma^\circ}),
\end{array}
\]

and if \( \Sigma \) is a flat \( R \)-algebra, we have a commutative diagram

\[
\begin{array}{ccc}
D(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}) \times D(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}) & \to & D(\text{Mod}_{\Omega \otimes_R \Sigma^\circ}) \\
\text{id} \times \text{res}_{\Lambda} & & \text{res}_{\Omega} \\
\text{res}_{\Lambda} \times \text{id} & & \\
D(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}) \times D(\text{Mod}_{\Lambda}) & \to & D(\text{Mod}_{\Omega}).
\end{array}
\]

We end this section with some general lemmas regarding the passing of tensor products through homomorphism groups and the resulting isomorphisms in the derived categories. Let us use \( \bar{m} \) to denote the degree of an element \( m \) of a term of a complex \( M \) of modules over a ring. We fix a fourth \( R \)-algebra \( \Xi \).

Lemma 2.1.6. Suppose that \( \Xi \) is a flat \( R \)-algebra and \( \Sigma \) is a projective \( R \)-algebra. Let \( A \) be a complex of \( \Omega \otimes_R \Lambda^\circ \)-modules, let \( B \) be a complex of \( \Lambda \otimes_R \Sigma^\circ \)-modules, and let \( C \) be a complex of \( \Omega \otimes_R \Xi^\circ \)-modules. Fix a quasi-isomorphism \( Q \to A \) of complexes of \( \Omega \otimes_R \Lambda^\circ \)-modules with \( Q \) \( q \)-flat over \( \Lambda^\circ \), a quasi-isomorphism \( P \to B \) of complexes of \( \Lambda \otimes_R \Sigma^\circ \)-modules with \( P \) \( q \)-projective over \( \Lambda \), and a quasi-isomorphism \( C \to I \) of complexes of \( \Omega \otimes_R \Xi^\circ \)-modules with \( I \) \( q \)-injective over \( \Omega \). Then the adjunction isomorphism

\[
\text{Hom}_\Omega(A \otimes \Lambda P, I) \to \text{Hom}_\Lambda(P, \text{Hom}_\Omega(A, I))
\]

\[
f \mapsto (p \mapsto (-1)^{\bar{a} \bar{p}}f(a \otimes p))
\]

induces an isomorphism

\[
\text{RHom}_\Omega(A \otimes_k^\Lambda B, C) \to \text{RHom}_\Lambda(B, \text{RHom}_\Omega(A, C))
\]

in \( D(\text{Mod}_{\Sigma \otimes_R \Xi^\circ}) \), as does the adjunction isomorphism

\[
\text{Hom}_\Omega(Q \otimes \Lambda B, I) \to \text{Hom}_\Lambda(B, \text{Hom}_\Omega(Q, I)).
\]
Proof. By Propositions 2.1.2 and 2.1.4, the complex \( \text{Hom}_\Omega(A \otimes \Lambda P, I) \) represents \( R \text{Hom}_\Omega(A \otimes L B, C) \), and the complex \( \text{Hom}_A(P, \text{Hom}_\Omega(A, I)) \) represents \( R \text{Hom}_A(B, R \text{Hom}_\Omega(A, C)) \). Therefore, we are reduced for the first part to showing that the adjunction map is an isomorphism of complexes, and this is standard (see [Lim2, Lemma 2.2]). The second part follows easily from the first part and the commutative diagram

\[
\begin{align*}
\text{Hom}_\Omega(Q \otimes \Lambda B, I) & \xrightarrow{\sim} \text{Hom}_A(B, \text{Hom}_\Omega(Q, I)) \\
\text{Hom}_\Omega(Q \otimes \Lambda P, I) & \xrightarrow{\sim} \text{Hom}_A(P, \text{Hom}_\Omega(Q, I)),
\end{align*}
\]
in that the left-hand vertical map is a quasi-isomorphism.

We consider the next isomorphism first on the level of complexes.

Lemma 2.1.7. Let \( A \) be a bounded complex of \( \Omega \otimes R \Sigma^\circ \)-modules that are flat as \( \Sigma^\circ \)-modules, let \( B \) be a complex of \( \Xi \otimes R \Lambda^\circ \)-modules that are finitely presented as \( \Lambda^\circ \)-modules, and let \( C \) be a complex of \( \Sigma \otimes R \Lambda^\circ \)-modules. Suppose also that either the terms of \( A \) are finitely presented as \( \Sigma^\circ \)-modules or at least one of \( B \) and \( C \) is bounded above and at least one is bounded below. Then the map

\[
A \otimes \Sigma \text{Hom}_{\Lambda^\circ}(B, C) \rightarrow \text{Hom}_{\Lambda^\circ}(A, A \otimes \Sigma C)
\]
\[
a \otimes f \mapsto (b \mapsto a \otimes f(b))
\]
is an isomorphism of complexes of \( \Omega \otimes R \Xi^\circ \)-modules.

Proof. That the stated map is a map of complexes is an easy check of the actions and signs. To see that it is an isomorphism, consider first the case that \( A, B, \) and \( C \) are concentrated in degree 0 and take a presentation

\[
F_1 \rightarrow F_2 \rightarrow B \rightarrow 0
\]

with \( F_1 \) and \( F_2 \) finitely generated free \( \Lambda^\circ \)-modules. Then the two rightmost vertical arrows in the commutative diagram with exact (noting the \( \Sigma^\circ \)-flatness of \( A \)) rows

\[
\begin{align*}
0 & \rightarrow A \otimes \Sigma \text{Hom}_{\Lambda^\circ}(B, C) \rightarrow A \otimes \Sigma \text{Hom}_{\Lambda^\circ}(F_2, C) \rightarrow A \otimes \Sigma \text{Hom}_{\Lambda^\circ}(F_1, C) \\
0 & \rightarrow \text{Hom}_{\Lambda^\circ}(B, A \otimes \Sigma C) \rightarrow \text{Hom}_{\Lambda^\circ}(F_2, A \otimes \Sigma C) \rightarrow \text{Hom}_{\Lambda^\circ}(F_1, A \otimes \Sigma C)
\end{align*}
\]

are isomorphisms of \( \Omega \)-modules by universal property of the direct sum and the commutativity of direct sums and tensor products, so the other is as well. Since the latter map is a morphism of complexes of \( \Omega \otimes R \Xi^\circ \)-modules, we have the result in the case of modules.
In the general setting, we have that

$$\operatorname{Hom}_{\Lambda^\circ}(B, A \otimes \Sigma C) = \prod_{j \in \mathbb{Z}} \operatorname{Hom}_{\Lambda^\circ}(B^j, \bigoplus_{i \in \mathbb{Z}} A^i \otimes \Sigma C^{n-i+j}).$$

Since $B^j$ is finitely presented over $\Lambda^0$, the argument given above implies that the latter group is naturally isomorphic to

$$\prod_{j \in \mathbb{Z}} \bigoplus_{i \in \mathbb{Z}} A^i \otimes \operatorname{Hom}_{\Lambda^\circ}(B^j, C^{n-i+j}).$$

On the other hand, we have

$$(A \otimes \Sigma \operatorname{Hom}_{\Lambda^\circ}(B, C))^n = \bigoplus_{i \in \mathbb{Z}} A^i \otimes \left( \prod_{j \in \mathbb{Z}} \operatorname{Hom}_{\Lambda^\circ}(B^j, C^{n-i+j}) \right).$$

If the terms of $A$ are finitely presented over $\Sigma^\circ$, then we can use a finite presentation of $A^i$ to see that the latter term is naturally isomorphic to

$$\bigoplus_{i \in \mathbb{Z}} \prod_{j \in \mathbb{Z}} A^i \otimes \operatorname{Hom}_{\Lambda^\circ}(B^j, C^{n-i+j}),$$

and the boundedness of $A$ allows us to commute the direct product and direct sum. Finally, if at least one of $B$ and $C$ is bounded above and at least one is bounded below, then the products over $j \in \mathbb{Z}$ involve only finitely many nonzero terms (again using that $A$ is bounded), and the result follows as direct sums commute with tensor products and each other.

In the derived category, we have the following generalization of [Ven, Proposition 6.1].

**Lemma 2.1.8.** Suppose that $\Omega$ is a flat $R$-algebra and $\Xi$ is a projective $R$-algebra. Let $A$ be a bounded above complex of $\Omega \otimes R \Sigma^\circ$-modules, let $B$ be a complex of $\Xi \otimes R \Lambda^\circ$-modules, and let $C$ be a bounded below complex of $\Sigma \otimes R \Lambda^\circ$-modules. Suppose that there exists a quasi-isomorphism $Q \to A$ of $\Omega \otimes R \Sigma^\circ$-modules, where $Q$ is bounded and has terms that are flat as $\Sigma^\circ$-modules. Suppose also that there is a quasi-isomorphism $P \to B$ of complexes of $\Xi \otimes R \Lambda^\circ$-modules, where $P$ is $q$-projective as a complex of $\Lambda^\circ$-modules with terms that are finitely presented over $\Lambda^\circ$. We assume also that either $C$ is bounded, $P$ is bounded above, or the terms of $Q$ are finitely presented as $\Sigma^\circ$-modules. Then the map

$$Q \otimes \Sigma \operatorname{Hom}_{\Lambda^\circ}(P, C) \to \operatorname{Hom}_{\Lambda^\circ}(P, Q \otimes \Sigma C)$$

gives rise to an isomorphism

$$A \otimes \Sigma\mathcal{R}\operatorname{Hom}_{\Lambda^\circ}(B, C) \xrightarrow{\sim} \mathcal{R}\operatorname{Hom}_{\Lambda^\circ}(B, A \otimes \Sigma C)$$

in $D(\text{Mod}_{\Omega \otimes R \Xi^\circ})$. 

Documenta Mathematica 18 (2013) 621–678
Proof. By Propositions 2.1.2 and 2.1.4, the complex \( Q \otimes \Sigma \text{Hom}_\Lambda^-(P, C) \) represents \( A \otimes R \text{Hom}_\Lambda^-(B, C) \) and the complex \( \text{Hom}_\Lambda^-(P, Q \otimes \Sigma) \) represents \( R \text{Hom}_\Lambda^-(B, A \otimes \Sigma) \). That the stated map is an isomorphism follows from Lemma 2.1.7.

Remark 2.1.9. In this article, we need only compute derived tensor products in the case that at least one of the complexes is bounded above and derived homomorphism complexes in the case that the target complex is bounded below. However, in Section 4.5, we will nevertheless be forced to represent derived homomorphism complexes using \( q \)-projective resolutions in an unbounded first variable. Hence, we have given a general treatment.

2.2 Modules over group rings

In this subsection, we preserve the notation of Section 2.1, and in addition, let \( G \) be a group. We begin by extending the notions of derived bifunctors of homorphism groups and tensor products to incorporate an additional action of \( G \).

If \( A \) is a complex of \( \Lambda[G] \)-modules and \( B \) is a complex of \( (\Lambda \otimes R \Sigma^\circ)[G] \)-modules, we give \( \text{Hom}_\Lambda^-(A, B) \) the structure of a complex of \( \Sigma^\circ[G] \)-modules via the standard \( G \)-action

\[
(g \cdot f)(a) = g \cdot f(g^{-1}a)
\]

for \( g \in G \), \( a \in A \), and \( f \in \text{Hom}_\Lambda^-(A, B) \). The following is then a slight weakening of the natural analogue of Proposition 2.1.2, written in condensed form.

Proposition 2.2.1. There is a derived bifunctor

\[
R \text{Hom}_\Lambda^-(\cdot, \cdot) : \text{D}(\text{Mod}_{\Lambda[G]}^\circ) \times \text{D}(\text{Mod}_{\Lambda \otimes R \Sigma^\circ[G]}) \rightarrow \text{D}(\text{Mod}_{\Sigma^\circ[G]}).
\]

Moreover, \( R \text{Hom}_\Lambda^-(A, B) \) can be represented by \( \text{Hom}_\Lambda^-(A, B) \) if \( A \) is \( q \)-projective as a complex of \( \Lambda \)-modules or, if \( \Sigma \) is \( R \)-flat, \( B \) is \( q \)-injective as a complex of \( \Lambda \)-modules.

Proof. Proposition 2.1.2 (with \( \Omega \) replaced by \( R[G]^\circ \) and \( \Sigma \) replaced by \( \Sigma^\circ[G] \)) implies the existence of derived bifunctors with the desired properties that take values in the category \( \text{D}(\text{Mod}_{R[G]^\circ \otimes R \Sigma^\circ[G]}) \). There is a natural exact functor

\[
\text{Mod}_{R[G]^\circ \otimes R \Sigma^\circ[G]} \rightarrow \text{Mod}_{\Sigma^\circ[G]}
\]

taking \( M \) to the same \( \Sigma^\circ \)-module with new \( G \)-action

\[
g \cdot m = (g^{-1} \otimes g) \cdot m
\]

for \( g \in G \) and \( m \in M \). This in turn induces a functor on derived categories, and composition of the above derived functor with this functor yields the result.
Next, if \( A \) is a complex of \((\Omega \otimes_R \Lambda^\circ)[G]\)-modules and \( B \) is a complex of \((\Lambda \otimes_R \Sigma^\circ)[G]\)-modules, we give \( A \otimes_A B \) the structure of a complex of \((\Omega \otimes_R \Sigma^\circ)[G]\)-modules via the \( G \)-action defined by \( g(a \otimes b) = ga \otimes gb \) for \( a \in A, b \in B \), and \( g \in G \). We state a very slight weakening (for brevity) of the analogue of Proposition 2.1.4.

**Proposition 2.2.2.** If \( \Omega \) or \( \Sigma \) is a flat \( R \)-algebra, then we have a derived bifunctor

\[
- \otimes^L_A : \text{D}(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}[G]) \times \text{D}(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}[G]) \to \text{D}(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}[G]).
\]

Moreover, \( A \otimes_A B \) represents \( \Lambda \otimes^L_A \mathbf{B} \) if either \( \Omega \) is \( R \)-flat and \( A \) is a \( q \)-flat as a complex of \( \Lambda^\circ \)-modules or \( \Sigma \) is \( R \)-flat and \( B \) is \( q \)-flat as a complex of \( \Lambda \)-modules.

**Proof.** Proposition 2.1.4 with \( \Omega \) replaced by \( \Omega[G] \) and \( \Sigma^\circ \) replaced by \( \Sigma^\circ[G] \) yields the existence of a derived bifunctor

\[
- \otimes^L_A : \text{D}(\text{Mod}_{\Omega \otimes_R \Lambda^\circ}[G]) \times \text{D}(\text{Mod}_{\Lambda \otimes_R \Sigma^\circ}[G]) \to \text{D}(\text{Mod}_{\Omega[G] \otimes_R \Sigma^\circ}[G])
\]

which has the desired properties. There is a natural exact functor

\[
\text{Mod}_{\Omega[G] \otimes_R \Sigma^\circ}[G] \to \text{Mod}_{(\Omega \otimes_R \Sigma^\circ)[G]}
\]

that takes an module \( M \) to the same \( \Omega \otimes_R \Sigma^\circ \)-module with new \( G \)-action

\[
g \cdot m = (g \otimes g) \cdot m
\]

for \( g \in G \) and \( m \in M \), and the desired bifunctor is the resulting composition of derived functors.

Suppose now that \( \Lambda \) is an \( R \)-algebra and that we are given a homomorphism \( \chi : G \to \text{Aut}_{\Lambda^\circ}(\Lambda) \), allowing us to endow \( \Lambda \) with the structure of a \( \Lambda^\circ[G] \)-module. We denote the resulting module by \( \chi \Lambda \). (If \( \chi \) is trivial, then we continue to write \( \Lambda \) for \( \chi \Lambda \).) We also have a map \( \chi^{-1} : G \to \text{Aut}_\Lambda(\Lambda) \) defined by \( \chi^{-1}(g)(\lambda) = \lambda \cdot \chi(g^{-1})(1) \) for \( g \in G \) and \( \lambda \in \Lambda \), so the resulting object \( \Lambda \chi \) is a \( \Lambda[G] \)-module. The relationship between \( \chi \Lambda \) and \( \Lambda \chi \) can be expressed by the evaluation-at-1 maps

\[
\text{Hom}_\Lambda(\chi \Lambda, \Lambda) \to \chi \Lambda \text{ and } \text{Hom}_{\Lambda^\circ}(\chi \Lambda, \Lambda) \to \Lambda \chi,
\]

which are isomorphisms of \( \Lambda^\circ[G] \) and \( \Lambda[G] \)-modules, respectively.

**Lemma 2.2.3.** Suppose that \( \Lambda \) is a flat \( R \)-algebra, and let \( \chi : G \to \text{Aut}_{\Lambda^\circ}(\Lambda) \) be a homomorphism. For any bounded above complex \( A \) of \( R[G] \)-modules that are finitely presented over \( R \) and any bounded below complex \( B \) of \( R \)-modules, the two maps

\[
\theta : \chi \Lambda \otimes_R \text{Hom}_R(A, B) \to \text{Hom}_\Lambda(\chi \Lambda \otimes_R A, \Lambda \otimes_R B)
\]

\[
\theta' : \Lambda \otimes_R \text{Hom}_R(A, B) \to \text{Hom}_{\Lambda^\circ}(\chi \Lambda \otimes_R A, \Lambda \otimes_R B)
\]

are isomorphisms.

---

**Meng Fai Lim and Romyar T. Sharifi**

**Documenta Mathematica 18 (2013) 621–678**
defined by \( \theta(\lambda \otimes f)(\mu \otimes x) = \mu \lambda \otimes f(x) \) and \( \theta'(\lambda \otimes f)(\mu \otimes x) = \lambda \mu \otimes f(x) \) are isomorphisms of complexes of \( \Lambda^\circ[G] \)-modules and of complexes of \( \Lambda[G] \)-modules, respectively.

Proof. We focus on the case of \( \theta \), as the other case follows from it. Since \( \chi \Lambda \) is \( R \)-flat, Lemma \[2.1.7\] (with \( \Omega = \Lambda^\circ[G] \) and \( \Xi = R[G] \)) implies that the natural map

\[ \chi \Lambda \otimes_R \text{Hom}_R(A, B) \xrightarrow{\sim} \text{Hom}_R(A, \chi \Lambda \otimes_R B) \]

is an isomorphism of complexes of \( \Lambda^\circ[G] \otimes_R R[G] \)-modules if we take the actions of \( G \) independently, and hence of \( \Lambda^\circ[G] \)-modules if we take the \( G \)-actions prescribed earlier in this subsection. The inverse of the isomorphism provided by the evaluation map provides the first of the isomorphisms of complexes of \( \Lambda^\circ[G] \)-modules

\[ \chi \Lambda \otimes_R B \xrightarrow{\sim} \text{Hom}_\Lambda(A, \Lambda \otimes_R B) \xrightarrow{\sim} \text{Hom}_\Lambda(A, \chi \Lambda \otimes_R B), \]

the canonical second map being an isomorphism as \( \Lambda \chi \) is free of rank 1 over \( \Lambda \). We therefore have an isomorphism

\[ \text{Hom}_R(A, \chi \Lambda \otimes_R B) \xrightarrow{\sim} \text{Hom}_R(A, \text{Hom}_\Lambda(A, \chi \Lambda \otimes_R B)). \]

Finally, the inverse of the adjoint morphism is an isomorphism

\[ \text{Hom}_R(A, \text{Hom}_\Lambda(A, \Lambda \otimes_R B)) \xrightarrow{\sim} \text{Hom}_\Lambda(A \otimes_R \Lambda, \Lambda \otimes_R B) \]

of complexes of \( \Lambda^\circ[G] \)-modules, and the resulting composite of three isomorphisms is easily computed to be \( \theta \).

2.3 Projective modules over a profinite ring

Let \( \Lambda \) be a profinite ring, and fix a directed fundamental system \( I \) of open neighborhoods of zero consisting of two-sided ideals of \( \Lambda \). We say that a topological \( \Lambda \)-module \( M \) is endowed with the \( I \)-adic topology if the collection \( \{\mathcal{M}\}_{\mathcal{M} \in I} \) forms a fundamental system of neighborhoods of zero. It was shown in \[Lim2, \text{Section 3.1}\] that any finitely generated compact (Hausdorff) \( \Lambda \)-module necessarily has the \( I \)-adic topology, and, moreover, any homomorphism between such modules is necessarily continuous.

In this subsection, we recall several facts about projective \( \Lambda \)-modules that will be of use to us. We denote the abelian category of compact \( \Lambda \)-modules by \( \mathcal{C}_\Lambda \). The free profinite \( \Lambda \)-module on a set \( X \) is canonically isomorphic to the topological direct product of one copy of \( \Lambda \) for each element of \( X \) \[Wil\ Proposition 7.4.1\], and a profinite \( \Lambda \)-module \( P \) is projective if and only if it is continuously isomorphic to a direct summand of the free profinite module on a set of generators of \( P \) \[Wil\ Proposition 7.4.7\]. In particular, the category \( \mathcal{C}_\Lambda \) has enough projectives. Any projective object in \( \mathcal{C}_\Lambda \) that is finitely generated over \( \Lambda \) is a projective \( \Lambda \)-module, and conversely, any finitely generated projective
Λ-module endowed with the \( \mathcal{I} \)-adic topology is a projective object in \( C_{\Lambda} \) [Lim2 Proposition 3.1.8].

Recall that the projective dimension of an abstract Λ-module \( M \) is the minimum integer \( n \) (if it exists) such that there is a resolution of \( M \) by projective Λ-modules

\[
0 \rightarrow P^{-n} \rightarrow \cdots \rightarrow P^{-1} \rightarrow P^0 \rightarrow M \rightarrow 0.
\]

The topological projective dimension of a compact Λ-module is defined similarly, replacing projective Λ-modules by projective objects in \( C_{\Lambda} \).

For the remainder of the subsection, we suppose that Λ is left Noetherian. Note that any projective resolution \( P \) of a finitely generated Λ-module \( M \) is quasi-isomorphic to a projective resolution \( Q \) of \( M \) by finitely generated Λ-modules via a map \( Q \rightarrow P \) compatible with the augmentations to \( M \). In particular, the projective dimension of \( M \) is the length of its shortest resolution by projectives in the category of finitely generated Λ-modules. It follows that the notions of projective dimension and topological projective dimension coincide on finitely generated (compact) Λ-modules.

In general, if \( \mathcal{C} \) is a category with objects that are Λ-modules, we will use \( \mathcal{C}_{\Lambda}^{\text{ft}} \) to denote the full subcategory of objects that are finitely generated (i.e., of finite type) over Λ. Since \( \text{Mod}_{\Lambda}^{\text{ft}} \) has enough projectives, the equivalent category \( \mathcal{C}_{\Lambda}^{\text{ft}} \) also has enough projectives. Denote by \( \mathbf{D}_{\Lambda}^{\text{ft}}(\text{Mod}_{\Lambda}) \) the full subcategory of the bounded above derived category \( \mathbf{D}^-(\text{Mod}_{\Lambda}) \) which has as its objects those bounded above complexes \( X \) of Λ-modules for which all of the \( H^i(X) \) are finitely generated Λ-modules. The following standard lemma tells us that any such complex is quasi-isomorphic to a complex of finitely generated modules. (See [Nek] Proposition 3.2.6 for an analogous statement, which has a similar proof.)

**Lemma 2.3.1.** Let \( \Omega \) be a left Noetherian ring. Every bounded above complex \( X \) of \( \Omega \)-modules for which every \( H^i(X) \) is a finitely generated \( \Omega \)-module has a quasi-isomorphic subcomplex of finitely generated \( \Omega \)-modules.

In sum, we have equivalences of categories

\[
\mathbf{D}^-(\mathcal{C}_{\Lambda}^{\text{ft}}) \cong \mathbf{D}^-(\text{Mod}_{\Lambda}^{\text{ft}}) \cong \mathbf{D}_{\Lambda}^{\text{ft}}(\text{Mod}_{\Lambda}),
\]

the first being induced by the forgetful functor and the second by the inclusion of categories \( \text{Mod}_{\Lambda}^{\text{ft}} \hookrightarrow \text{Mod}_{\Lambda} \). We use these equivalences to identify these categories with each other.

### 2.4 Completed tensor products

In this subsection, we review some basic facts about completed tensor products and briefly study their derived functors. Let \( R \) be a commutative profinite ring, and let \( \Lambda, \Omega, \) and \( \Sigma \) be profinite \( R \)-algebras, by which we shall mean that they are profinite and the maps from \( R \) to their centers are continuous.
Let $\mathcal{I}$ (resp., $\mathcal{J}$) denote a directed fundamental system of open neighborhoods of zero consisting of two-sided ideals of $\Lambda$ (resp., $\Omega$). We then define a completed tensor product algebra by
\[
\Omega \hat{\otimes}_R \Lambda^\circ = \lim_{\leftarrow A \in \mathcal{I}, B \in \mathcal{J}} \Omega / \mathfrak{A} \otimes_R (\Lambda / \mathfrak{A})^\circ.
\]
This is clearly a profinite $R$-algebra.

We shall denote the category of compact $\Omega \hat{\otimes}_R \Lambda^\circ$-modules by $\mathcal{C}_{\Omega^\circ \Lambda^\circ}$. Let $M$ be an object of $\mathcal{C}_{\Omega^\circ \Lambda^\circ}$, and let $N$ be an object of $\mathcal{C}_{\Lambda^\circ \Sigma^\circ}$. By [RZ, Lemma 5.1.1(a)], we have that the set of open, finite index $\Omega \hat{\otimes}_R \Lambda^\circ$-submodules (resp., $\Lambda \hat{\otimes}_R \Sigma^\circ$-submodules) of $M$ (resp., $N$) forms a basis of neighborhoods of zero on $M$ (resp., $N$). We define the completed tensor product to be the compact $\Omega \hat{\otimes}_R \Sigma^\circ$-module
\[
M \hat{\otimes}_\Lambda N = \lim_{\leftarrow M', N'} M / M' \otimes_\Lambda N / N',
\]
where $M'$ and $N'$ run through the respective bases for $M$ and $N$, with the topology defined by the inverse limit. The completed tensor product is associative and commutative (i.e., $M \hat{\otimes}_\Lambda N \cong N \hat{\otimes}_\Lambda M$) in the same sense as the usual tensor product.

Note that the canonical $\Lambda$-balanced map
\[
t: M \times N \to M \hat{\otimes}_\Lambda N
\]
induces a homomorphism
\[
M \otimes_\Lambda N \to M \hat{\otimes}_\Lambda N
\]
of $\Omega \hat{\otimes}_R \Sigma^\circ$-modules that has dense image. The completed tensor product of $M$ and $N$ then satisfies the following universal property (see [RZ, Section 5.5] in the case that $\Omega = \Sigma = R$).

**Lemma 2.4.1.** For any compact $\Omega \hat{\otimes}_\Lambda \Sigma^\circ$-module $L$ and any continuous, $\Lambda$-balanced, left $\Omega$-linear and right $\Sigma$-linear map $f: M \times N \to L$, there is a unique continuous map $\hat{f}: M \hat{\otimes}_\Lambda N \to L$ of $\Omega \hat{\otimes}_R \Sigma^\circ$-modules such that $\hat{f} \circ t = f$.

It follows that, in defining the completed tensor product, it suffices to run through a basis of neighborhoods of zero consisting of open $\Omega \hat{\otimes}_R \Lambda^\circ$-submodules of $M$ and a basis of neighborhoods of zero consisting of open $\Lambda \hat{\otimes}_R \Sigma^\circ$-submodules of $N$.

The following is also standard.

**Lemma 2.4.2.** Let $M$ and $N$ be objects of $\mathcal{C}_{\Omega^\circ \Lambda^\circ}$ and $\mathcal{C}_{\Lambda^\circ \Sigma^\circ}$, respectively.

(a) Suppose that $M = \lim_{\alpha} M_\alpha$ and $N = \lim_{\beta} N_\beta$, where each $M_\alpha$ (resp., $N_\beta$) is a compact $\Omega \hat{\otimes}_R \Lambda^\circ$-module (resp., compact $\Lambda \hat{\otimes}_R \Sigma^\circ$-module). Then there is an isomorphism
\[
M \hat{\otimes}_\Lambda N \cong \lim_{\alpha, \beta} M_\alpha \hat{\otimes}_\Lambda N_\beta
\]
of compact $\Omega \hat{\otimes}_R \Sigma^\circ$-modules.
Meng Fai Lim and Romyar T. Sharifi

The canonical map $M \otimes \Lambda N \to M \hat{\otimes} \Lambda N$ is an isomorphism if either $M$ is finitely generated as a $\Lambda^\circ$-module or $N$ is finitely generated as a $\Lambda$-module.

The functor $M \hat{\otimes} \Lambda - : C_{\Lambda^\circ} \to C_{\Omega^\circ}$ is right exact.

The next lemma describes connections between projective objects in different categories of compact modules and flat objects in categories of abstract modules. A ring is said to be left (resp., right) coherent if all its finitely generated left (resp., right) ideals are finitely presented.

**Lemma 2.4.3.**

(a) If $\Lambda$ is left (resp., right) coherent, then every projective object in $C_{\Lambda^\circ}$ (resp., $C_\Lambda$) is flat with respect to the usual left (resp., right) tensor product over $\Lambda$.

(b) If $\Omega$ (resp., $\Lambda$) is a projective object of $C_R$, then every projective object in $C_{\Omega^\circ}$ is a projective object in $C_{\Lambda^\circ}$ (resp., $C_\Omega$).

**Proof.** (a) Since every projective object in $C_{\Lambda^\circ}$ is continuously isomorphic to a direct summand of a direct product of copies of $\Lambda^\circ$, it suffices to show that any direct product of copies of $\Lambda$ is flat as an abstract $\Lambda^\circ$-module. By a theorem of Chase (cf. [Lam, Theorem 4.47]), this is equivalent to the fact that $\Lambda$ is left coherent.

(b) Suppose that $\Omega$ is projective in $C_R$, so $\Omega$ is continuously isomorphic to a direct summand of a direct product of copies of $R$. Lemma 2.4.2(a) then tells us that $\Omega \hat{\otimes} R \Lambda^\circ$ is topologically a direct summand of a direct product of copies of $\Lambda^\circ$, hence is projective.

Let $G$ be a profinite group. We use $C_{\Lambda,G}$ to denote the category of compact $\Lambda$-modules with a continuous commuting action of $G$, the morphisms being continuous homomorphisms of $\Lambda[G]$-modules. Note the following.

**Remark 2.4.4.** The category $C_{\Lambda,G}$ is equivalent to the category $C_{\Lambda[G]}$, where $\Lambda[G]$ is given the profinite topology defined by $\Lambda[G] \cong \lim_{\Delta \in \mathcal{I}} \lim_{N} (\Lambda/N)[G/N]$, where $N$ runs over the open normal subgroups of $G$.

Consequently, $C_{\Lambda,G}$ is an abelian category with enough projectives, and every element of $C_{\Lambda,G}$ is an inverse limit of finite $\Lambda[G]$-quotients (see also [Lim2, Section 3.2]). Moreover, $\Lambda[G]$ is a projective object of $C_\Lambda$ by [RZ, Lemma 1.4.1].
5.3.5(d)], so the forgetful functor $\mathcal{C}_{\Lambda,G} \to \mathcal{C}_{\Lambda}$ takes projective objects to projective objects. To shorten notation, we use $\mathcal{C}_{\Lambda-\Sigma,G}$ to denote the category $\mathcal{C}_{\Lambda \otimes R \Lambda^\circ, G}$.

We remark that if $M$ and $N$ are, respectively, objects of $\mathcal{C}_{\Omega-\Lambda,G}$ and $\mathcal{C}_{\Lambda-\Sigma,G}$, possibly with trivial $G$-actions, we may give $\hat{M} \otimes \Lambda N$ the structure of an object of $\mathcal{C}_{\Omega-\Sigma,G}$ via the diagonal action of $G$. That is, the $G$-action is defined by choosing bases of open $(\Omega \otimes R \Lambda^\circ)[G]$-submodules of $M$ (resp., $(\Lambda \otimes R \Sigma^\circ)[G]$-submodules of $N$) and taking the inverse limits of the tensor products of the finite quotients.

**Remark 2.4.5.** The analogous result to Lemma 2.4.2 holds, as a consequence of said lemma, if we take $M$ and $N$ to be objects of $\mathcal{C}_{\Omega-\Lambda,G}$ and $\mathcal{C}_{\Lambda-\Sigma,G}$, respectively. (That is, in part (a), one must take $M_\alpha$ and $N_\beta$ to be objects of these categories to attain an isomorphism in $\mathcal{C}_{\Omega-\Sigma,G}$, and in part (c), the functor is now a functor from $\mathcal{C}_{\Lambda-\Sigma,G}$ to $\mathcal{C}_{\Omega-\Sigma,G}$.)

Note that we may form completed tensor products of bounded above complexes, or of a bounded complex with any complex, as with the usual tensor products.

**Proposition 2.4.6.** If $\Omega$ is projective in $\mathcal{C}_R$, then the completed tensor product induces the following derived bifunctor

$$- \hat{\otimes}^L_{\Lambda} : \mathcal{D}^{-}(\mathcal{C}_{\Omega-\Lambda,G}) \times \mathcal{D}^{-}(\mathcal{C}_{\Lambda-\Sigma,G}) \to \mathcal{D}^{-}(\mathcal{C}_{\Omega-\Sigma,G}),$$

where $A \hat{\otimes} \Lambda B$ represents $A \hat{\otimes}^L_{\Lambda} B$ if the terms of $A$ are projective as objects in $\mathcal{C}_{\Lambda^\circ}$. Furthermore, there is a commutative diagram

$$\begin{array}{c}
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Lambda,G}) \times \mathcal{D}^{-}(\mathcal{C}_{\Lambda-\Sigma,G}) \\
\downarrow \\
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Sigma,G}) \end{array} \quad \rightarrow \quad \begin{array}{c}
\mathcal{D}^{-}(\mathcal{C}_{\Lambda-\Sigma,G}) \\
\downarrow \\
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Sigma,G}) \end{array}$$

in which the vertical arrows are induced by forgetful functors, and if $\Lambda$ is left Noetherian, there is a commutative diagram

$$\begin{array}{c}
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Lambda,G}) \times \mathcal{D}^{-}(\mathcal{C}_{\Lambda-\Sigma,G}) \\
\downarrow \\
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Sigma,G}) \end{array} \quad \rightarrow \quad \begin{array}{c}
\mathcal{D}^{-}(\mathcal{C}_{\Lambda-\Sigma,G}) \\
\downarrow \\
\mathcal{D}^{-}(\mathcal{C}_{\Omega-\Sigma,G}) \end{array}$$

in which the vertical arrows are induced by forgetful functors and embeddings of categories.
Proof. The proof of the first part and the commutativity of the first set of diagrams follow by similar arguments to those of Propositions 2.1.2 and 2.2.2, making use of Lemma 2.4.3(b) (using bounded above complexes of projective objects in place of \( q \)-projective complexes). The commutativity of the final diagram then follows from Lemmas 2.4.2(b) and 2.4.3.

Let \( \text{Ch}^b_{\Lambda^+} \) denote the category of bounded complexes in \( \text{C}_{\Omega^-\Lambda,G} \) that are quasi-isomorphic to bounded complexes in \( \text{C}_{\Omega^-\Lambda,G} \) of objects that are projective in \( \text{C}_{\Lambda^+} \), and let \( \text{D}^b_{\Lambda^+} \) denote its derived category.

**Proposition 2.4.7.** If \( \Omega \) is projective in \( \text{C}_R \), then we have a derived bifunctor

\[
- \hat{\otimes}_\Lambda : \text{D}^b_{\Lambda^+} \times \text{D}(\text{C}_{\Lambda^-\Sigma,G}) \to \text{D}(\text{C}_{\Omega^-\Sigma,G}),
\]

where \( A \hat{\otimes}_\Lambda B \) represents \( A \otimes^L \Lambda B \) if \( A \) is a bounded complex with terms that are projectives in \( \text{C}_{\Lambda^+} \).

Proof. Let \( B \) be a complex of objects of \( \text{C}_{\Omega^-\Lambda,G} \). Since every object of \( \text{Ch}^b_{\Lambda^+} \) is by definition quasi-isomorphic to a bounded complex of objects that are acyclic for the functor \( - \hat{\otimes}_\Lambda B \), we have a derived functor \( - \hat{\otimes}_\Lambda B \). Let \( A \) be a bounded complex in \( \text{C}_{\Omega^-\Lambda,G} \) of projectives in \( \text{C}_{\Lambda^+} \) and \( f : B \to B' \) be a quasi-isomorphism. Then \( f \) induces isomorphisms between the \( E_2 \)-terms of the convergent spectral sequence

\[
E_2^{i,j}(B) = H^i(A \hat{\otimes}_\Lambda B^j) \Rightarrow H^{i+j}(A \hat{\otimes}_\Lambda B)
\]

and its analogue for \( B' \), and therefore it induces isomorphisms on the abutments.

2.5 Ind-admissible modules

The notion of an ind-admissible \( R[G] \)-module was introduced in [Nek, Section 3.3] for a complete commutative Noetherian local ring \( R \) with finite residue field and a profinite group \( G \). An \( R[G] \)-module is ind-admissible if it can be written as a union of \( R[G] \)-submodules that are finitely generated over \( R \) and on which \( G \) acts continuously with respect to the topology defined by the maximal ideal of \( R \). In this section, we discuss an analogous construction of ind-admissible modules over noncommutative profinite rings.

As in Nekovar’s treatment, we do not consider the seemingly delicate issue of placing topologies on ind-admissible modules, as it proves unnecessary. In particular, it is still possible to define the continuous cochain complex of an ind-admissible module as a direct limit.

We maintain the notation of Section 2.4. Moreover, we suppose that \( \Omega \) is left Noetherian and \( \Lambda \) is right Noetherian. For an \( (\Omega \otimes_R \Lambda^\omega)[G] \)-module \( M \), we denote by \( S(M) \) the set of \( (\Omega \otimes_R \Lambda^\omega)[G] \)-submodules of \( M \) that are finitely generated as \( \Lambda^\omega \)-modules and on which \( \Omega \) and \( G \) act continuously with respect to the \( I \)-adic topology. The following is a straightforward generalization of [Nek, Lemma 3.3.2].
Lemma 2.5.1. Let $M$ be an $(\Omega \otimes_R \Lambda^\circ)[G]$-module.

(a) If $M' \in S(M)$, then $N \in S(M)$ for every $(\Omega \otimes_R \Lambda^\circ)[G]$-submodule $N$ of $M'$.

(b) If $f : M \to N$ is a homomorphism of $(\Omega \otimes_R \Lambda^\circ)[G]$-modules and $M' \in S(M)$, then $f(M') \in S(N)$.

(c) If $M', M'' \in S(M)$, then $M' + M'' \in S(M)$.

Proof. For part (a), Corollary 3.1.6 and Proposition 3.1.7 of [Lim2] imply that the subspace topology on $N$ from the $I$-adic topology on $M'$ agrees with the $I$-adic topology on $N$, which implies that $\Omega$ and $G$ act continuously on $N$. In (b), the continuity of the $\Omega$ and $G$-actions on the finitely generated $\Lambda^\circ$-module $f(M')$ is a consequence of the fact that the map $M' \to f(M')$ is a continuous quotient map with respect to the $I$-adic topology (as follows from Corollary 3.1.5 and Proposition 3.1.7 of [Lim2]). Part (c) follows from (b), using the addition map $M \times M \to M$.

Note that Lemma 2.5.1(c) implies that $S(M)$ is a directed set with respect to inclusion. We say that an $(\Omega \otimes_R \Lambda^\circ)[G]$-module $M$ is (right) ind-admissible if

$$M = \bigcup_{N \in S(M)} N.$$  

We list some basic properties of the full subcategory $\mathcal{F}_{\Omega-\Lambda,G}$ of Mod$_{(\Omega \otimes_R \Lambda^\circ)[G]}$ with objects the ind-admissible $(\Omega \otimes_R \Lambda^\circ)[G]$-modules.

Lemma 2.5.2.

(a) The category $\mathcal{F}_{\Omega-\Lambda,G}$ is abelian and stable under subobjects, quotients and colimits.

(b) The embedding functor

$$i : \mathcal{F}_{\Omega-\Lambda,G} \hookrightarrow \text{Mod}_{(\Omega \otimes_R \Lambda^\circ)[G]}$$

is exact and is left adjoint to the functor

$$j : \text{Mod}_{(\Omega \otimes_R \Lambda^\circ)[G]} \to \mathcal{F}_{\Omega-\Lambda,G}$$

that takes a module $M$ to the union of the elements of $S(M)$.

(c) The category $\mathcal{F}_{\Omega-\Lambda,G}$ has enough injectives.

(d) Let $M$ be an ind-admissible $(\Omega \otimes_R \Lambda^\circ)[G]$-module, and let $N$ be a finitely generated $\Lambda^\circ$-submodule of $M$. Then $(\Omega \otimes_R \Lambda^\circ)[G] \cdot N$ is an ind-admissible $(\Omega \otimes_R \Lambda^\circ)[G]$-module which is a finitely generated $\Lambda^\circ$-module.

Documenta Mathematica 18 (2013) 621–678
(e) Let \( M \) be an \((\Omega \otimes_R \Lambda^\circ)[G]\)-module. Then \( M \in S(M) \) if and only if \( M \) is an ind-admissible \((\Omega \otimes_R \Lambda^\circ)[G]\)-module which is finitely generated as a \( \Lambda^\circ \)-module.

Proof. For parts (a), (b) and (c), similar arguments to those of [Nek] Proposition 3.3.5] apply. The “only if” direction of (e) is obvious. For (d), since \( N \) is \( \Lambda^\circ \)-finitely generated, we can find a finite subset \( \{M_1, \ldots, M_n\} \) of \( S(M) \) such that

\[
N \subseteq M_1 + \cdots + M_n.
\]

The assertion then follows from Lemma 2.5.3(c) and the “only if” direction of (e). The “if” direction of (e) follows from (d), since \( M = (\Omega \otimes_R \Lambda^\circ)[G] \cdot M \).

If \( G \) is trivial, we write \( \mathcal{I}_{\Omega-\Lambda} \) for \( \mathcal{I}_{\Omega-\Lambda,G} \). We leave to the reader the proof of the following.

**Lemma 2.5.3.**

(a) Let \( M \) be an \((\Omega \otimes_R \Lambda^\circ)[G]\)-module. If \( N \) is an \((\Omega \otimes_R \Lambda^\circ)[G]\)-submodule of \( M \), then \( N \in S(M) \) if and only if \( N \) is an object of \( C^\Lambda_{\Omega-\Lambda,G} \).

(b) The category \( \mathcal{I}_{\Omega-\Lambda,G} \) is equivalent to the ind-category of \( C^\Lambda_{\Omega-\Lambda,G} \).

(c) The category \( \mathcal{I}_{\Omega-\Lambda} \) is equivalent to the full subcategory of \( \mathcal{I}_{\Omega-\Lambda,G} \) with objects the modules on which \( G \) acts trivially.

**Remark 2.5.4.** In the case that \( \Omega = R \), we denote \( \mathcal{I}_{R-\Lambda,G} \) by \( \mathcal{I}_{\Lambda,G} \), and the latter category is equivalent to the ind-category of \( C^\Lambda_{\Lambda,G} \). The subcategory \( \mathcal{I}_{\Lambda^\circ} \) is simply Mod_{\Lambda^\circ}.

**Lemma 2.5.5.** Let \( A \) be an object of \( C^\Lambda_{\Omega,G} \), and let \( B \) be an object of \( C^\Lambda_{\Omega-\Lambda,G} \). Then \( \hom_{\Omega}(A, B) \) with the \( I \)-adic topology is an object of \( C^\Lambda_{\Lambda,G} \).

Proof. Since \( A \) is finitely generated over \( \Omega \) and \( B \) is a compact \( \Omega \)-module, we have by [Lim2] Lemma 3.1.4[3] that \( \hom_{\Omega}(A, B) = \hom_{\Omega,cts}(A, B) \), where the latter group is the group of continuous homomorphisms of \( \Omega \)-modules. Note that \( \Lambda^\circ \) acts continuously on \( \hom_{\Omega}(A, B) \) with respect to the compact-open topology by [Flo] Proposition 3[3], and similarly \( G \) acts continuously on it as a consequence of [Flo] Lemma 2. We have a continuous isomorphism of \( \Lambda^\circ[G]\)-modules

\[
\hom_{\Omega}(A, B) \xrightarrow{\sim} \varprojlim_{\beta} \hom_{\Omega}(A, B_{\beta}),
\]

where \( B_{\beta} \) runs over the finite Hausdorff \((\Omega \otimes_R \Lambda^\circ)[G]\)-quotients of \( B \). As \( B_{\beta} \) is finite and therefore discrete, the group \( \hom_{\Omega}(A, B_{\beta}) \) is finite and discrete as well, so \( \hom_{\Omega}(A, B) \) is compact.

Note that \( \hom_{\Omega}(A, B) \) injects into \( \hom_{\Omega}(\Omega^r, B) \cong B^r \) for some \( r \geq 0 \), since \( A \) is \( \Omega \)-finitely generated. We therefore have that \( \hom_{\Omega}(A, B) \) is \( \Lambda^\circ \)-finitely generated. Finally, [Lim2] Proposition 3.1.7 then implies that the compact-open topology on \( \hom_{\Omega}(A, B) \) agrees with the \( I \)-adic topology.
We define
\[ \text{Hom}_{\Omega,\text{cts}}(-, -): C_{\Omega,G} \times \mathcal{F}_{\Omega-\Lambda,G} \rightarrow \mathcal{F}_{\Lambda^*,G}. \]
by
\[ \text{Hom}_{\Omega,\text{cts}}(A, B) = \lim_{\alpha} \lim_{\beta} \text{Hom}_{\Omega}(A_\alpha, B_\beta), \]
upon making the identifications
\[ A_\alpha = \lim_{\leftarrow} A_\alpha, \]
where \( A_\alpha \) runs over the quotients of \( A \) in \( C_{\Omega,G}^{-ft} \), and
\[ B_\beta = \lim_{\rightarrow} B_\beta, \]
where \( B_\beta \) runs over the elements of \( S(B) \), i.e.,
by Lemma 2.5.3 the subobjects of \( B \) that lie in \( C_{\Omega^{-ft},G}^{\Lambda^*} \). Note that it actually suffices to let \( A_\alpha \) and \( B_\beta \) run over cofinal subsets.

**Remark 2.5.6.** We note that
\[ \text{Hom}_{\Omega,\text{cts}}(A, B) \cong \lim_{\beta} \text{Hom}_{\Omega,\text{cts}}(A, B_\beta), \]
where \( \text{Hom}_{\Omega,\text{cts}}(A, B_\beta) \) here is the \((\Omega \otimes R^{\Lambda^*})[G]\)-module of continuous \( \Omega \)-module homomorphisms in the usual sense.

We also note the following.

**Lemma 2.5.7.** Let \( A \) be an object of \( C_{\Omega,G}^{-ft} \), and let \( B \) be an object of \( \mathcal{F}_{\Omega-\Lambda,G} \). Then we have
\[ \text{Hom}_{\Omega,\text{cts}}(A, B) = \text{Hom}_{\Omega}(A, B). \]

**Proof.** This follows from the computation
\[ \text{Hom}_{\Omega,\text{cts}}(A, B) \cong \lim_{\beta} \text{Hom}_{\Omega,\text{cts}}(A, B_\beta) = \lim_{\beta} \text{Hom}_{\Omega}(A, B_\beta) \cong \text{Hom}_{\Omega}(A, B), \]
the latter isomorphism following from the case in which \( A \) is free of finite rank, since \( A \) is finitely presented over \( \Omega \).

As usual, we may extend our definition to consider the complex of continuous homomorphisms from a complex of compact modules to a complex of ind-admissible modules, supposing that at least one of these complexes is bounded above and at least one is bounded below.

**Proposition 2.5.8.** There is a derived bifunctor
\[ \mathbf{R}\text{Hom}_{\Omega,\text{cts}}(-, -): D^- (C_{\Omega,G})^\circ \times D^+ (\mathcal{F}_{\Omega-\Lambda,G}) \rightarrow D^+ (\mathcal{F}_{\Lambda^*,G}), \]
and \( \mathbf{R}\text{Hom}_{\Omega,\text{cts}}(A, B) \) can be represented by \( \text{Hom}_{\Omega,\text{cts}}(A, B) \) if the terms of \( A \) are projective as objects of \( C_{\Omega} \). Moreover, we have a commutative diagram
\[
\begin{array}{ccc}
D^-(C_{\Omega,G})^\circ \times D^+ (\mathcal{F}_{\Omega-\Lambda,G}) & \xrightarrow{\mathbf{R}\text{Hom}_{\Omega,\text{cts}}(-, -)} & D^+ (\mathcal{F}_{\Lambda^*,G}) \\
\downarrow & & \downarrow \\
D^-(C_{\Omega,G}^{-ft})^\circ \times D^+ (\mathcal{F}_{\Omega-\Lambda,G}) & \xrightarrow{\mathbf{R}\text{Hom}_{\Omega}(-, -)} & D^+ (\text{Mod}_{\Lambda^*[G]}) \\
\downarrow & & \downarrow \\
D^-(\text{Mod}_{\Omega[G]})^\circ \times D^+ (\text{Mod}_{(\Omega \otimes R^{\Lambda^*})[G]}) & \xrightarrow{\mathbf{R}\text{Hom}_{\Omega}(-, -)} & D^+ (\text{Mod}_{\Lambda^*[G]})
\end{array}
\]
Proof. The existence of the derived bifunctor in question follows from an argument similar to that of Proposition 2.1.2, and the second statement is a consequence of the fact that a projective object in $C_{\Omega,G}$ is a projective object of $C_{\Omega}$, noting Remark 2.5.6.

Let $A$ be a bounded above complex of objects of $C_{\Omega-G}^{\Omega-ft}$, and let $B$ be a bounded below complex of objects of $\mathscr{A}_{\Omega-\Lambda,G}$. Choose bounded above complexes $L$, $P$ and $Q$, consisting of projective objects in $C_{\Omega,G}$, $\text{Mod}_{\Omega[G]}$ and $\text{Mod}_{\Omega-G}^{\Omega-ft}$ (i.e., $C_{\Omega-G}^{\Omega-ft}$) respectively, with quasi-isomorphisms to $A$ of complexes in the respective categories. Projectivity yields maps $Q \to L$, $Q \to P$ and $P \to L$ of complexes in $C_{\Omega}$, $\text{Mod}_{\Omega}$ and $\text{Mod}_{\Omega[G]}$, respectively. We then have a commutative diagram

$$
\begin{array}{ccc}
\text{Hom}_{\Omega,\text{cts}}(L,B) & \longrightarrow & \text{Hom}_{\Omega,\text{cts}}(Q,B) \\
\downarrow & & \downarrow \\
\text{Hom}_{\Omega}(P,B) & \longrightarrow & \text{Hom}_{\Omega}(Q,B).
\end{array}
$$

Here, the right-hand vertical arrow is the identity map by Lemma 2.5.7 (viewing $Q$ as a complex of objects in $C_{\Omega-G}^{\Omega-ft}$ with trivial $G$-action), and the lower horizontal map is a quasi-isomorphism as a consequence of Proposition 2.2.1, as $\Omega[G]$ is $\Omega$-free. We want to show that the left-hand vertical arrow is a quasi-isomorphism of complexes of $\Lambda^0[G]$-modules, and we will be done if we can show the upper horizontal arrow is a quasi-isomorphism of complexes of $\Lambda^0$-modules.

In the case that $B$ is a module, exactness of direct limit reduces us to the case that $B$ is an object of $C_{\Omega-G}^{\Lambda^0-ft}$, hence of $C_{\Omega}$. In this case, since both $L$ and $Q$ are complexes of projectives in $C_{\Omega}$, we obtain that the map is a quasi-isomorphism. In the general setting, since $L$ and $Q$ are bounded above and $B$ is bounded below, we have

$$
\text{Hom}_{\Omega,\text{cts}}^n(X,B) = \bigoplus_{j \in \mathbb{Z}} \text{Hom}_{\Omega,\text{cts}}(X^j,B^{j+n})
$$

for $X = L$ and $X = Q$, and the direct sum commutes with direct limits. As $B$ is the direct limit of its truncations $\tau_{\leq i}B$ (with $i$th terms $\ker d^j_B$), we may therefore assume that $B$ is bounded with $B^j = 0$ for $j > i$. In this case, brutal truncations (i.e., $\sigma_{\leq i}B$ having $i$th term $B^j$) provide an exact triangle

$$(\sigma_{\leq i-1}B)[i-1] \to B^i \to (\sigma_{\leq i}B)[i] \to (\sigma_{\leq i-1}B)[i],$$

and we are reduced recursively to the above-proven case of a module.

The following analogue of Lemma 2.2.3 will be of later use.
Lemma 2.5.9. Suppose that $\Lambda$ is a flat, Noetherian $R$-algebra, and let $\chi: G \to \text{Aut}_{\Lambda^e}(\Lambda)$ be a homomorphism. Let $A$ be a bounded above complex of objects in $C_{R,G}$, and let $B$ be a bounded below complex of $R$-modules. Then there are isomorphisms

$$
\theta: \chi \Lambda \otimes_R \text{Hom}_{R,cts}(A, B) \to \text{Hom}_{\Lambda^e,cts}(\chi \Lambda \Lambda \otimes_R A, \Lambda \otimes_R B)
$$

$$
\theta': \chi \Lambda \otimes_R \text{Hom}_{R,cts}(A, B) \to \text{Hom}_{\Lambda^e,cts}(\chi \Lambda \Lambda \otimes_R A, \Lambda \otimes_R B)
$$

that arise as direct limits of the maps in Lemma 2.2.3.

Proof. Write $A = \lim_{\leftarrow} A_\alpha$ with $A_\alpha$ an object of $C_{R,ft}_{R,G}$ and $B = \lim_{\to} B_\beta$ with $B_\beta$ an object of $C_{R,ft}$. Note that

$$
\chi \Lambda \otimes_R A_\alpha \cong \lim_{\leftarrow} \chi \Lambda \otimes_R A_\alpha,
$$

so, applying Lemma 2.2.3, we have

$$
\text{Hom}_{\Lambda,cts}(\chi \Lambda \Lambda \otimes_R A, \Lambda \otimes_R B) = \lim_{\alpha,\beta} \chi \Lambda \otimes_R \text{Hom}_R(A_\alpha, B_\beta)
$$

$$
\cong \chi \Lambda \otimes_R \text{Hom}_{R,cts}(A_\alpha, B_\beta)
$$

$$
\cong \chi \Lambda \otimes_R \text{Hom}_{R,cts}(A, B).
$$

This yields the first isomorphism, and the argument for the second is similar.

Let $M$ be an ind-admissible $(\Omega \otimes_R \Lambda^e)[G]$-module. The continuous cochain complex of $G$ with values in $M$ is the complex of $\Omega \otimes_R \Lambda^e$-modules that is the direct limit of complexes

$$
C(G, M) = \lim_{N \in S(M)} C(G, N),
$$

where $C(G, N)$ is the usual complex of (inhomogeneous) continuous cochains, with $N$ given the $I$-adic topology.

We remark that, in this definition, it clearly suffices to take the direct limit over a cofinal subset of $S(M)$. In particular, if $M$ itself is finitely generated over $\Lambda^e$, then by Lemma 2.2.3(e) the above definition of $C(G, M)$ as a direct limit agrees with its definition as continuous cochains, considering $M$ as an object of $C_{\Omega,\Lambda[G]}$. Finally, we can extend the above definition to consider the total cochain complex of a complex $M$ of ind-admissible modules, which has $k$th term

$$
C^k(G, M) = \bigoplus_{i+j=k} C^i(G, M^j)
$$

and differentials as in [Nek (3.4.1.3)], and the cochain functor induces a functor

$$
\text{RI}^*(G, -): D^+(\mathcal{A}_{\Omega,\Lambda[G]}) \to D^+(\text{Mod}_R \otimes_R \Lambda^e)
$$

between derived categories.
In this paper, we are interested in the case that our profinite ring $\Lambda$ is the Iwasawa algebra of a compact $p$-adic Lie group. With this in mind, we introduce some notation that will be used from this point forward. Fix a prime $p$. Let $R$ be a commutative complete Noetherian local ring with maximal ideal $m$ and residue field $k$, where $k$ is finite of characteristic $p$. We let $\Gamma$ denote a compact $p$-adic Lie group. We are interested in the completed group ring $\Lambda = R[[\Gamma]]$.

We note that $\Lambda$ is a profinite ring, endowed with the topology given by the canonical isomorphism

$$\Lambda \cong \lim_{\leftarrow} \bigoplus_{u \in \mathcal{U}} \lim_{n \to \infty} R/m^n[\Gamma/U],$$

where $\mathcal{U}$ denotes the set of open normal subgroups of $\Gamma$. In fact, it is a projective object in $\mathcal{C}_R$ (cf. [RZ, Lemma 5.3.5(d)]). Moreover, we have the following (cf. [Wil, Theorem 8.7.8]).

**Proposition 3.0.1.** The ring $\Lambda$ is Noetherian.

**Proof.** As $R$ is a complete local Noetherian ring with finite residue field $k$, the Cohen structure theorem ([Coh, Theorem 12]) implies that it is isomorphic to a quotient of a power series ring $S$ in $n = \dim k/m/m^2$ variables over the ring of Witt vectors $O$ of $k$. Therefore, $R[[\Gamma]]$ is a quotient of $S[[\Gamma]]$, so it suffices to prove that $S[[\Gamma]]$ is Noetherian. Since $S[[\Gamma]] \cong O[[\mathbb{Z}_p \times \Gamma]]$ and $\mathbb{Z}_p \times \Gamma$ is a compact $p$-adic Lie group, we have that $S[[\Gamma]]$ is Noetherian by a mild extension of a classical theorem of Lazard’s (cf. [Ven2, Corollary 2.4] and [Laz, Proposition V.2.2.4]).

Since Noetherian rings are necessarily coherent, we may apply Lemma 2.4.3(a) to conclude from Proposition 3.0.1 that $\Lambda$ is a flat $R$-algebra.

### 3.1 Induced modules and descent

In this subsection, we will exhibit an interesting spectral sequence relating the cohomology of an induced module over an Iwasawa algebra to the cohomology of the module itself. We start work in a more general setting.

Let $G$ be a profinite group. Let $\Sigma$ be a left coherent and right Noetherian profinite $R$-algebra. For a complex $M$ of objects in $\mathcal{C}_\Sigma, G$, we let $C(G, M)$ denote its total direct sum complex of continuous $G$-cochains (cf. the end of Section 2.3), we let $R\Gamma(G, M)$ denote the corresponding object in $D(\text{Mod}_\Sigma)$, and we let $H^i(G, M)$ denote its $i$th continuous $G$-cohomology (or, more precisely, hypercohomology) group. As in [Lim2, Proposition 3.2.11], the functor

$$R\Gamma(G, -) : D^+(\mathcal{C}_\Sigma, G) \to D^+(\text{Mod}_\Sigma)$$

is well-defined and exact. (While $\mathcal{C}_\Sigma, G$ may not have enough injectives, the treatment of [KS] asserts the existence of $D^+(\mathcal{C}_\Sigma, G)$ and $D(\mathcal{C}_\Sigma, G)$ under certain set-theoretic assumptions, which we make here.)
In the case that $G$ has finite $p$-cohomological dimension, we can do better. For a double complex $X$ (or, by abuse of notation, its total complex) and $n \in \mathbb{Z}$, we let $\tau_{\leq n}(X)$ (resp., $\tau_{\geq n}(X)$) be the total complex of the quotient complex (resp., subcomplex) of $X$ with $j$th row equal to $\tau_{\geq n}(X^j)$ (resp., $\tau_{\leq n}(X^j)$). For lack of a sufficiently precise reference, we provide a short proof of the following.

**Lemma 3.1.1.** Suppose that $G$ has finite $p$-cohomological dimension. Then we have a convergent hypercohomology spectral sequence

$$E_2^{i,j} = H^i(G, H^j(M)) \Rightarrow H^{i+j}(G, M)$$

for any complex $M$ of objects in $C_{\Sigma, G}$.

**Proof.** Since $G$ has finite cohomological dimension, for sufficiently large $k$ we have a convergent hypercohomology spectral sequence

$$E_2^{i,j} = H^i(G, H^j(M)) \Rightarrow H^{i+j}(\tau_{\leq k}C(G, M))$$

arising from the filtration on rows of the indicated truncation of the double $G$-cochain complex of $M$ (cf. [NSW, §II.2]). As $C(G, M)$ is the direct limit of the complexes $\tau_{\leq k}C(G, M)$ under maps that are quasi-isomorphisms by the above convergence, the natural map

$$H^{i+j}(\tau_{\leq k}C(G, M)) \to H^{i+j}(G, M)$$

is an isomorphism by exactness of the direct limit. 

As quasi-isomorphisms of complexes induce isomorphisms on the truncated double complexes defining their hypercohomology spectral sequences, we have the following corollary.

**Corollary 3.1.2.** Suppose that $G$ has finite $p$-cohomological dimension. The functor $C(G, -)$ preserves quasi-isomorphisms of chain complexes and induces an exact functor

$$R\Gamma(G, -) \colon D(C_{\Sigma, G}) \to D(\text{Mod}_\Sigma).$$

Fix a profinite $R$-algebra $\Omega$ that is a projective object of $C_R$ for the remainder of the section. We now derive the following spectral sequence.

**Proposition 3.1.3.** Let $Y$ be a complex of objects in $C_{\Sigma, G}$, and let $N$ be a bounded above complex of objects in $C_{\Omega^-\Sigma}$. Consider the conditions

(1) $G$ has finite $p$-cohomological dimension,

(2) $N$ is bounded with terms of finite projective dimension over $\Sigma^\circ$.

If (1) holds and $Y$ is bounded above, (2) holds and $Y$ is bounded below, or both (1) and (2) hold, then we have an isomorphism

$$N \otimes_{\Sigma^\circ} R\Gamma(G, Y) \simto R\Gamma(G, N \otimes_{\Sigma^\circ} Y)$$

in $D(\text{Mod}_\Omega)$. 

**Documenta Mathematica** 18 (2013) 621–678
Proof. Let $L$ be a bounded above complex of projective objects in $\mathcal{C}_{\Omega-\Sigma}$ mapping quasi-isomorphically to $N$. If (1) holds and $Y$ is bounded above, we set $P = L$, and we have by Proposition 2.4.6 that $P \otimes_{\Sigma} Y$ represents $N \otimes_{\Sigma} Y$ in $D^-(\mathcal{C}_{\Omega,G})$. Otherwise, there exists a quasi-isomorphic bounded quotient complex $P = \tau_{\geq n} L$ of $L$ of objects in $\mathcal{C}_{\Omega-\Sigma}$, through which the quasi-isomorphism $L \to N$ factors, such that the terms of $P$ are projective in $\mathcal{C}_{\Sigma^\omega}$. Proposition 2.4.7 then tells us that $P \otimes_{\Sigma} Y$ represents $N \otimes_{\Sigma} Y$ in $D^-(\mathcal{C}_{\Omega,G})$. In all cases, the terms of $P$ are flat $\Sigma^\omega$-modules by Lemma 2.4.3, so Proposition 2.1.4 tells us that $P \otimes_{\Sigma} C(G,Y)$ represents $N \otimes_{\Sigma} R\Gamma(G,Y)$ in $D(\text{Mod}_{\Omega})$.

We have a map of complexes of $\Omega$-modules

$$P \otimes_{\Sigma} C(G,Y) \to C(G, P \otimes_{\Sigma} Y)$$

with sign conventions as in [Nek, Proposition 3.4.4]. (The continuity of the cochains in the image is insured, for instance, by the fact that any term of $P$ is a topological direct summand of a direct product of copies of $\Sigma$.) It suffices to show that this map is a quasi-isomorphism.

Let $Q$ be a bounded above complex of finitely generated projective $\Sigma^\omega$-modules mapping quasi-isomorphically to $N$, which we take to be bounded if (2) holds. We then have a map of complexes of $R$-modules

$$Q \otimes_{\Sigma} C(G,Y) \to C(G, Q \otimes_{\Sigma} Y)$$

that, much as in [Nek, Proposition 3.4.4], is an isomorphism. (To see that it is an isomorphism, note that it is immediate if $Q$ is a finitely generated free $\Sigma^\omega$-module, and therefore also for direct summands of such, i.e., the finitely generated projective $\Sigma^\omega$-modules. The case of a complex is then immediate.) By the projectivity of $Q$ in both the categories of abstract and compact $\Sigma^\omega$-modules, we have a commutative diagram

$$
\begin{array}{ccc}
Q \otimes_{\Sigma} C(G,Y) & \longrightarrow & C(G, Q \otimes_{\Sigma} Y) \\
\downarrow & & \downarrow \\
P \otimes_{\Sigma} C(G,Y) & \longrightarrow & C(G, P \otimes_{\Sigma} Y)
\end{array}
$$

in which the vertical arrows are quasi-isomorphisms of complexes of $R$-modules, noting Lemma 2.4.2(b) and, when (1) holds, Corollary 3.1.2. It follows that the lower horizontal arrow is a quasi-isomorphism as well.

We make a couple of remarks.

Remark 3.1.4. Suppose that $G$ is a finite group. The proof of Proposition 3.1.3 under condition (2) then goes through word-for-word for bounded $Y$, with Tate cochains and the resulting derived complexes replacing the usual cochains of $G$ and its derived complexes.
Remark 3.1.5. In [FK1, Proposition 1.6.5(3)], an identical isomorphism to that of Proposition 3.1.3 is proved for a very general class of “adic” rings Ω and Λ, with stronger conditions on G, N, and Y.

From now on, we focus on case that Σ is the Iwasawa algebra Λ = \( R[\Gamma] \). Fix a continuous homomorphism \( \chi : G \to \Gamma \) of profinite groups. Since Γ may be viewed as a subgroup of \( \text{Aut}_A(\Lambda) \) by left multiplication, we may define the \( \Lambda \otimes R[\Gamma] \)-module \( \chi A \) as in Section 2.2. If \( A \) is a \( \Lambda \otimes R \)-module, we then set \( \chi A = \chi A \otimes \Lambda A \) and \( A \chi = A \otimes \Lambda \chi \), which are \( \Lambda \otimes [G] \) and \( [G] \)-modules, respectively.

Let \( M \) be a \( R[G] \)-module. As in [Lim2, Section 5.1], we define a \( \Lambda_\otimes [G] \)-module \( F_\Gamma(M) \) by

\[
F_\Gamma(M) = \lim_{U \in \mathcal{U}} (R[\Gamma/U] \otimes_R M)
\]

with \( G \) acting diagonally and \( \Lambda \) acting on the left on the terms in the inverse limit. This construction applied to compact modules provides a functor

\[
F_\Gamma : C_{R,G} \longrightarrow C_{\Lambda,G},
\]

which is exact as \( R[\Gamma/U] \) is \( R \)-flat and the inverse limit is exact on inverse systems in \( C_{\Lambda,G} \). We extend this to an exact functor on complexes in the obvious fashion.

Given an complex \( T \) of objects in \( C_{R,G} \), we have, noting Lemma 2.4.2(a), a natural continuous isomorphism

\[
\mathcal{F}_T(T) \cong A \hat{\otimes}_R T
\]

of complexes in \( C_{\Lambda,G} \). We may therefore use Lemma 2.4.2(b) to note that \( \mathcal{F}_T \) takes a complex \( T \) of objects in \( C_{R,G}^{\text{ft}} \) to the complex \( \Lambda \hat{\otimes}_R T \) of objects in \( C_{\Lambda,G}^{\text{ft}} \). We make the latter identification freely.

We now supply a key ingredient for descent.

Lemma 3.1.6. Let \( T \) be a complex in \( C_{R,G} \). Let \( \Gamma' \) be a quotient of \( \Gamma \) by a closed normal subgroup, and set \( \Lambda' = R[\Gamma'] \). Let \( N \) be a bounded above complex of objects of \( C_{\Omega - \Lambda'} \). Then \( N \) can be viewed as a complex of objects in \( C_{\Omega - \Lambda} \) via the quotient map \( \pi : \Lambda \to \Lambda' \). Suppose either that \( T \) is bounded above or that \( N \) is bounded and its terms have finite projective dimension in \( C_{\Lambda'} \) and in \( C_{(\Lambda')}^{\text{ft}} \). Then \( \pi \) induces an isomorphism

\[
N \hat{\otimes}_\Lambda \mathcal{F}_T(T) \simto N \hat{\otimes}_{\Lambda'} \mathcal{F}_{T'}(T)
\]

in \( D^- (C_{\Omega,G}) \).

Proof. Let \( Q \to N \) be a quasi-isomorphism, where \( Q \) is a bounded above complex of \( C_{\Omega - \Lambda'} \)-projectives, and note that its terms are projective objects of \( C_{(\Lambda')}^{\text{ft}} \) by Lemma 2.4.2(b). If \( N \) is bounded with terms of finite projective dimension
in \( C(\Lambda') \), then for sufficiently small \( n \), the truncation \( \tau_n Q \) also consists of projectives in \( C(\Lambda') \), so we may assume in that case that \( Q \) is bounded. Next, and similarly, let \( P \to Q \) be a quasi-isomorphism in \( C_\Omega \) with \( P \) a bounded above complex in \( C_\Omega \) of projectives in \( C_{\Lambda'} \), and suppose that \( P \) is bounded if \( N \) is bounded with terms having finite projective dimension in \( C_{\Lambda'} \). The derived completed tensor products in question are then represented by \( P \hat{\otimes} \Lambda \chi \hat{\otimes} R T \) and \( Q \hat{\otimes} \Lambda' \chi \hat{\otimes} R T \), respectively, by Propositions 2.4.6 and 2.4.7. Since the induced map \( P \hat{\otimes} \Lambda \chi \to Q \hat{\otimes} \Lambda' \chi \) is clearly a quasi-isomorphism and the terms of these complexes are projective in \( C_{\Lambda'} \), we have by the same propositions the desired quasi-isomorphism between the two complexes.

We are particularly interested in the case that the complex \( N \) above is the Iwasawa algebra of a quotient of \( \Gamma \), for which the following lemma is crucial.

**Lemma 3.1.7.** Let \( \Gamma_0 \) be a closed normal subgroup of \( \Gamma \) with no elements of order \( p \). Set \( \Gamma' = \Gamma / \Gamma_0 \) and \( \Lambda' = R[\Gamma'] \). Then \( \Lambda' \) has finite projective dimension over \( \Lambda \).

**Proof.** Let \( c\text{-Tor}^\Xi_i (\_ , \_) \) denote the \( i \)th derived bifunctor of the completed tensor product over a profinite \( R \)-algebra \( \Xi \). A standard argument yields a convergent spectral sequence

\[
H_i(\Gamma, c\text{-Tor}^R_j(\Lambda', Z)) \Rightarrow c\text{-Tor}_i^{\Lambda_\chi}(\Lambda', Z)
\]

for any compact \( \Lambda \)-module \( Z \), as in [NSW, §V.2, Exercise 3], where elements of \( \Gamma \) act inversely on \( \Lambda_\chi \)-modules and diagonally on completed \( R \)-tensor products. Since \( \Lambda' \) is a projective object in \( C_R \), the spectral sequence degenerates to yield isomorphisms

\[
H_n(\Gamma, \Lambda' \hat{\otimes} R Z) \cong c\text{-Tor}^\Lambda_n(\Lambda', Z).
\]

Moreover, by a standard extension of Shapiro’s lemma [RZ Theorem 6.10.9], we have

\[
H_n(\Gamma_0, Z) \cong H_n(\Gamma, \Lambda' \hat{\otimes} R Z).
\]

Since \( \Gamma_0 \) has finite \( p \)-cohomological dimension by [Ser, Corollaire 1], there then exists \( n_0 \geq 0 \) independent of \( Z \) such that \( c\text{-Tor}_n^\Lambda(\Lambda', Z) = 0 \) for every \( n > n_0 \). It follows from [NSW, Proposition 5.2.11] that \( \Lambda' \) has finite topological projective dimension as a compact \( \Lambda \)-module, so it has finite projective dimension over \( \Lambda \) by the discussion of Section 2.3.

The following descent spectral sequence is reduced by the above results to a special case of Proposition 3.1.8.

**Theorem 3.1.8.** Let \( T \) be a complex in \( C_{R,G} \). Let \( \Gamma' \) be a quotient of \( \Gamma \) by a closed normal subgroup \( \Gamma_0 \), and set \( \Lambda' = R[\Gamma'] \). Consider the conditions

1. \( G \) has finite cohomological dimension,
2. \( \Gamma_0 \) contains no elements of order \( p \).
Suppose that (1) holds and \( T \) is bounded above, (2) holds and \( T \) is bounded below, or both (1) and (2) hold. Then we have an isomorphism
\[
\Lambda' \otimes_{\Lambda} R\Gamma(G, \mathcal{F}_T(T)) \cong R\Gamma(G, \mathcal{F}_{\Lambda'}(T))
\]
in \( \mathbf{D}(\text{Mod}_{\Lambda'}) \).

**Proof.** This is simply Proposition 3.1.3 for \( N = \Lambda' \) and \( Y = \mathcal{F}_T(T) \), noting Lemma 3.1.7 and applying the isomorphism of Lemma 3.1.6.

3.2 Finite generation of cohomology groups

In this subsection, we shall show that the cohomology groups of induced modules are finitely generated under a certain assumption on the group. We maintain the notation of the previous subsection. In particular, \( \Gamma \) is a compact \( p \)-adic Lie group, \( R \) is a complete commutative local Noetherian ring with finite residue field of characteristic \( p \), and \( \Lambda = R[\Gamma] \). Moreover, we are given a continuous homomorphism \( \chi : G \to \Gamma \) from a profinite group \( G \).

**Lemma 3.2.1.** Suppose that \( \Gamma \) is pro-\( p \). Let \( M \) be a compact \( \Lambda \)-module. Then \( M \) is finitely generated over \( \Lambda \) if and only if \( R \otimes_{\Lambda} M \) is finitely generated over \( R \).

**Proof.** Since \( \Gamma \) is pro-\( p \), the Jacobson radical \( \mathfrak{m} \) of \( \Lambda \) is \( \mathfrak{m}\Lambda + I \), where \( I \) is the augmentation ideal of \( \Lambda \) (see [NSW, Proposition 5.2.16(iii)]). This implies that
\[
M/\mathfrak{m}M \cong M_{\Gamma}/\mathfrak{m}M_{\Gamma},
\]
where \( M_{\Gamma} = M/I \). Therefore, Nakayama’s lemma tells us that \( M_{\Gamma} \) is finitely generated over \( R \) if and only if \( M/\mathfrak{m}M \) is finite. On the other hand, Nakayama’s lemma for compact \( \Lambda \)-modules (cf. [NSW Lemma 5.2.18(ii)]) tells us that \( M \) is finitely generated over \( \Lambda \) if and only if \( M/\mathfrak{m}M \) is finite.

Lemma 3.2.1 requires a compact \( \Lambda \)-module. Therefore, we give a sufficient condition for an abstract \( \Lambda \)-module to be a compact \( \Lambda \)-module under an appropriate topology.

**Lemma 3.2.2.** Suppose that \( M \) is an abstract \( \Lambda \)-module which is the inverse limit of an inverse system of finite quotient modules. Then \( M \) is a compact \( \Lambda \)-module with respect to the resulting profinite topology.

**Proof.** We need only to show that the \( \Lambda \)-action
\[
\theta : \Lambda \times M \to M
\]
is continuous with respect to the topology given by the inverse limit. Suppose first that \( M \) is finite. Let \( \mathfrak{m} \) denote the Jacobson radical of \( \Lambda \). Then \( \mathfrak{m}^n M \) stabilizes, and it follows from Nakayama’s lemma that we have \( \mathfrak{m}^n M = 0 \) for large enough \( n \). By [NSW, Corollary 5.2.19], there exist \( r \geq 0 \) and \( U \in \mathcal{U} \)
such that \( m^r \Lambda + I(U) \subseteq M^n \), where \( I(U) \) denotes the ideal of \( \Lambda \) generated by the augmentation ideal in \( R[U] \). Hence, \( \theta \) is continuous with respect to the discrete topology on \( M \).

In general, we can write \( M \cong \varprojlim M/M_\alpha \), where \( \{ M_\alpha \} \) is a directed system of \( \Lambda \)-submodules of finite index. Let \( (\lambda, x) \in \theta^{-1}(y + M_\alpha) \) for \( \lambda \in \Lambda \) and \( x, y \in M \).

Since \( M/M_\alpha \) is finite, it follows from the above discussion that there exist \( r \) and \( U \) such that

\[
(\lambda + m^r \Lambda + I(U)) \cdot (x + M_\alpha) \subseteq y + M_\alpha,
\]
as desired. \( \square \)

We shall also require the following lemma.

**Lemma 3.2.3.** If \( M \) is a finitely generated \( \Lambda \)-module, then \( \text{Tor}_i^\Lambda(R, M) \) is finitely generated over \( R \) for every \( i \geq 0 \).

**Proof.** To see this, we first choose a resolution \( P \) of \( M \) consisting of finitely generated projective \( \Lambda \)-modules. Then \( R \otimes_\Lambda P \) is a complex of finitely generated \( R \)-modules. Therefore, the homology groups \( \text{Tor}_i^\Lambda(R, M) \) of the latter complex are finitely generated over \( R \). \( \square \)

We recall from [Nek] Proposition 4.2.3 that if \( G \) is a profinite group such that \( H^i(G, M) \) is finite for every finite \( G \)-module \( M \) of \( p \)-power order and \( i \geq 0 \), then \( H^i(G, T) \) is a finitely generated \( R \)-module for every \( T \in C_{R,G}^{R-\text{ft}} \) and \( i \geq 0 \). We will refer to a profinite group \( G \) as \( p \)-cohomologically finite if there exists an integer \( n \) such that, for every finite \( G \)-module \( M \) of \( p \)-power order, \( H^i(G, M) = 0 \) for all \( i > n \) and \( H^i(G, M) \) is finite for all \( i \). We remark that if \( G \) is \( p \)-cohomologically finite, then so is every open subgroup of \( G \), as follows directly from Shapiro’s lemma.

**Theorem 3.2.4.** Suppose that \( G \) is \( p \)-cohomologically finite. Let \( T \) be a complex of objects in \( C_{R,G}^{R-\text{ft}} \). Then the cohomology groups \( H^i(G, \mathcal{F}_T(T)) \) are finitely generated over \( \Lambda \) for all \( i \). That is, \( R^i(G, \mathcal{F}_T(T)) \) is an object of \( D_{\Lambda-\text{pt}}(\text{Mod}_\Lambda) \).

**Proof.** Suppose for now that \( T \) is concentrated in degree 0. Let \( \Gamma_0 \) be an open uniform normal pro-\( p \)-subgroup of \( \Gamma \), and set \( H = \chi^{-1}(\Gamma_0) \). Fix a set of double coset representatives \( \gamma_1, \ldots, \gamma_t \) of \( \Gamma_0 \backslash \Gamma / \chi(G) \). For each \( i \), define \( \chi_i : G \to \Gamma \) by \( \chi_i(g) = \gamma_i g \gamma_i^{-1} \). The reader may check that

\[
\bigoplus_{i=1}^t \left( \mathbb{Z}[G] \otimes_{\mathbb{Z}[H]} R[\Gamma_0]_{\chi_i} \right) \cong \Lambda_X
\]

is an isomorphism of \( R[\Gamma_0][G] \)-modules. Given this, Shapiro’s lemma induces isomorphisms

\[
H^i(G, \mathcal{F}_T(T)) \cong \bigoplus_{i=1}^t H^i(H, R[\Gamma_0]_{\chi_i} \otimes_R T)
\]

**Documenta Mathematica** 18 (2013) 621–678
Nekovář Duality

of \( R[[\Gamma_0]]\)-modules. The finite generation of \( H^1(G, \mathcal{F}_T(T)) \) over \( \Lambda \) then reduces to the finite generation of each \( H^1(H, R[[\Gamma_0]]_I \otimes_R T) \) over \( R[[\Gamma_0]] \). Thus, we can and do assume that \( \Gamma \) has no elements of finite order.

Since \( R \) has finite projective dimension over \( \Lambda \) by Lemma 3.1.7, Theorem 3.1.8 provides the convergent spectral sequence

\[
E^{r,s}_2 = \text{Tor}^{\Lambda}_{r-s}(R, H^s(G, \mathcal{F}_T(T))) \Rightarrow H^{r+s}(G, T).
\]

Since \( G \) has finite \( p \)-cohomological dimension, say \( n \), we may suppose induc- 

tively that \( H^i(G, \mathcal{F}_T(T)) \) is a finitely generated \( \Lambda \)-module for all \( i \) greater than some \( j \leq n \). Note that \( E^{0,j}_\infty \) is a quotient of \( E^{0,j}_2 \) and that \( H^j(G, T) \) is a finitely generated \( R \)-module by [Nek, Proposition 4.2.3]. Since \( E^{0,j}_\infty \) is a quotient of \( H^j(G, T) \), it is also a finitely generated \( R \)-module. On the other hand, it follows from the definition of \( E^{0,j}_2 \) that the kernel of the surjective map \( E^{0,j}_2 \to E^{0,j}_\infty \) is isomorphic to a subquotient of the finite direct sum

\[
\bigoplus_{i=j+1}^n E^{j-i, i}_2 = \bigoplus_{i=j+1}^n \text{Tor}^{\Lambda}_{i-1}[R, H^i(G, \mathcal{F}_T(T))].
\]

By our induction hypothesis and Lemma 3.2.3, the above module is a finitely generated \( R \)-module. It follows that

\[
E^{0,j}_2 \cong R \otimes_{\Lambda} H^j(G, \mathcal{F}_T(T))
\]

is a finitely generated \( R \)-module. As \( H^j(G, \mathcal{F}_T(T)) \) is an inverse limit of finite \( \Lambda \)-modules by [Lim2, Proposition 5.2.4], Lemma 3.2.2 gives it the structure of a compact \( \Lambda \)-module, and we may therefore apply Lemma 3.2.1 to conclude that \( H^j(G, \mathcal{F}_T(T)) \) is finitely generated over \( \Lambda \).

Now let us work without condition on \( \Gamma \) or the complex \( T \). By Lemma 3.1.4 and the exactness of \( \mathcal{F}_T(-) \), we have the convergent spectral sequence of \( \Lambda \)-modules

\[
H^r(G, \mathcal{F}_T(H^s(T))) \Rightarrow H^{r+s}(G, \mathcal{F}_T(T)).
\]

Thus, \( H^i(G, \mathcal{F}_T(T)) \) has a filtration consisting of subquotients of the finitely generated \( \Lambda \)-modules \( H^i(G, \mathcal{F}_T(H^{i-j}(T))) \) with \( 0 \leq j \leq n \). Consequently, \( H^i(G, \mathcal{F}_T(T)) \) is also a finitely generated \( \Lambda \)-module.

**Remark 3.2.5.** In the case that \( \Gamma \) is abelian, Theorem 3.2.4 for bounded below \( T \) is essentially [Nek, Proposition 4.2.3], as \( R[[\Gamma_0]] \) for an open pro-\( p \), torsion-free subgroup \( \Gamma_0 \) is itself a commutative complete local Noetherian ring with finite residue field. In the case that \( T \) is a bounded complex of \( R \)-projectives, it is a corollary of [FK1, Proposition 1.6.5(2)].

### 3.3 Duals of induced modules

In this subsection, we describe the pairings and the resulting cup products that will be used in proving a duality theorem for the cohomology of induced
modules. Key to our discussion is the following lemma, which we record for convenience. We let \( \Omega \) and \( \Sigma \) denote auxiliary Iwasawa algebras: e.g., \( \Omega = R[\Phi] \) for some compact \( p \)-adic Lie group \( \Phi \).

**Lemma 3.3.1.** Suppose that \( M \) is a bounded above complex of objects of \( C_{\Omega-\Lambda,G} \), let \( N \) be a bounded above complex of objects of \( C_{\Lambda-\Sigma,G} \), and let \( L \) be a bounded above complex of objects of \( C_{\Omega-\Sigma,G} \). Then any map

\[
\phi: M \otimes_{\Lambda} N \to L
\]

of complexes in \( C_{\Omega-\Sigma,G} \) gives rise to a cup product morphism

\[
\cup: C(G,M) \otimes_{\Lambda} C(G,N) \to C(G,L)
\]

of complexes of \( \Omega \otimes_{\Lambda} \Sigma^\vee \)-modules.

**Proof.** Briefly, the point is that to give such a map \( \phi \) is equivalent to producing a collection of continuous, \( \Lambda \)-balanced, \( G \)-equivariant, left \( \Omega \)-linear, and right \( \Sigma \)-linear pairings

\[
\langle -, - \rangle_{mn}: M^m \times N^n \to L^{m+n}
\]

that are compatible with coboundaries in the sense of [Lim2, Section 3.3]. The cup product then arises from the induced cup products

\[
\cup_{ij}^{ij}: C^i(G,M^m) \otimes_{\Lambda} C^j(G,N^n) \to C^{i+j}(G,L^{m+n})
\]

by combining them to a map of the total complexes with appropriate signs as in [Nek, (3.4.5.2)]; \( \cup = (-1)^{imjn} \cup_{ij}^{ij} \).

Let us fix some notation. Let \( \iota: \Lambda \to \Lambda \) denote the unique continuous \( R \)-algebra homomorphism that satisfies \( \iota(\gamma) = \gamma^{-1} \) for all \( \gamma \in \Gamma \). If \( A \) is a \( \Lambda[G] \)-module, we let \( A^\iota \) denote the \( \Lambda^\iota[G] \)-module that is \( A \) as an \( R[G] \)-module but on which any \( \lambda \in \Lambda \) now acts by left multiplication by \( \iota(\lambda) \). We extend this to complexes in the obvious fashion. Of particular interest to us is \( \mathcal{F}_T(T)^\iota \) for a complex \( T \) of objects in \( C_{R,G} \). Since \( \iota \) induces a continuous isomorphism of \( \Lambda^\iota[G] \)-modules \( \chi^\iota \Lambda \xrightarrow{\sim} \Lambda^\iota \), we can and will make the identification

\[
\mathcal{F}_T(T)^\iota = \chi^\iota \Lambda \otimes_R T,
\]

of complexes in \( C_{\Lambda,\iota,G} \) from this point forward.

**Lemma 3.3.2.** For objects \( M \) and \( N \) in \( C_{R,G} \), the pairing

\[
\langle -, - \rangle: \mathcal{F}_T(M) \times \mathcal{F}_T(N)^\iota \to \Lambda \otimes_R (M \otimes_R N)
\]

\[
(\lambda \otimes m, \mu \otimes n) \mapsto \lambda \mu \otimes m \otimes n
\]

is continuous, \( R \)-balanced, \( G \)-equivariant with respect to the trivial action on \( \Lambda \) in the target, and is left and right \( \Lambda \)-linear. Moreover, if \( M \) and \( N \) are bounded above complexes of objects in \( C_{R,G} \), we have a morphism

\[
\phi: \mathcal{F}_T(M) \otimes_R \mathcal{F}_T(N)^\iota \to \Lambda \otimes_R (M \otimes_R N)
\]

of complexes in \( C_{\Lambda-\Lambda,G} \).
Proof. We begin by remarking that by Lemma 2.4.1 it makes sense to define
the pairing on pairs of tensors, identified with their images in the completed
tensor product. The pairing is clearly \( R \)-balanced, and the reader can check the
statements on the \( \Lambda, \Lambda^\circ \), and \( G \)-actions. The continuity of the pairing reduces
immediately to the continuity of multiplication on \( \Lambda \). The second statement
follows easily.

We next apply these pairings to study a duality between induced modules. As
described in the introduction, the dualizing complex for \( R \) is an object
\( \omega_R \) of \( D_{R-\text{ft}}(\text{Mod}_R) \) with the property that for every object \( M \) of \( D(\text{Mod}_{R-\text{ft}}) \), the object \( R\text{Hom}_R(M,\omega_R) \) lies in \( D_{R-\text{ft}}(\text{Mod}_R) \) and the canonical morphism
\[
M \longrightarrow R\text{Hom}_R(R\text{Hom}_R(M,\omega_R),\omega_R)
\]
is an isomorphism in \( D(\text{Mod}_R) \). A dualizing complex exists for \( R \) and is unique
up to translation and isomorphism in \( D_{R-\text{ft}}(\text{Mod}_R) \) (see [Har1, Ch. V]). We
choose a bounded complex \( J_R \) of injective \( R \)-modules which represents a choice
of the dualizing complex in \( D(\text{Mod}_R) \). (See [Nek, Section 0.4], or Section 4.3
below, for the construction of such a complex.)

Let \( T \) be a bounded complex of objects in \( C_{R,G} \). Then \( \text{Hom}_R(T,J_R) \) is a
bounded complex of “admissible” \( R[G] \)-modules with cohomology groups that
are finitely generated over \( R \) (see [Nek, (4.3.2)]). By [Nek, Proposition 3.3.9],
there is a subcomplex \( T^* \) of \( \text{Hom}_R(T,J_R) \) which is a complex of objects in \( C_{R,G}^{R-\text{ft}} \) (giving said objects the \( \mathfrak{m} \)-adic topology) and is quasi-isomorphic to
\( \text{Hom}_R(T,J_R) \) via the inclusion map.

We have a composite morphism
\[
\pi: T \otimes_R T^* \longrightarrow T \otimes_R \text{Hom}_R(T,J_R) \longrightarrow J_R
\]
of complexes of \( R[G] \)-modules, the first morphism being induced by the inclusion
and the second being the usual evaluation map. By Lemma 3.3.2, this in turn induces a composite map
\[
\varpi: \mathcal{F}_T(T) \otimes_R \mathcal{F}_T(T^*)^i \overset{\delta}{\longrightarrow} \Lambda \otimes_R T \otimes_R T^* \otimes_R J_R
\]
of complexes of \( (\Lambda \otimes_R \Lambda^\circ)[G] \)-modules. Twisting \( \varpi \) by the identity map on
an auxiliary bounded above complex of objects of \( \mathcal{C}_{\Omega-\Lambda}^{\Lambda^\circ-\text{ft}} \), Lemma 3.3.1 now
provides the cup product morphisms of the following lemma, which will be
used in the next section. For a continuous character \( \kappa: G \rightarrow R^\times \) and an \( R[G] \)-
module \( M \), we let \( M(\kappa) \) denote the \( R \)-module \( M \) with the new commuting
\( G \)-action given by the twist of the original by \( \kappa \). (In addition, \( M(\kappa) \) will be
taken to maintain any topology and actions of profinite \( R \)-algebras with which
\( M \) may be endowed.)

Lemma 3.3.3. Let \( A \) be a bounded above complex of objects in \( \mathcal{C}_{\Omega-\Lambda}^{\Lambda^\circ-\text{ft}} \), and let
\( \kappa: G \rightarrow R^\times \) be a continuous homomorphism. The map \( \varpi_A \) defined above induces a map
\[
\varpi_A: A \otimes_R \mathcal{F}_T(T) \otimes_R \mathcal{F}_T(T^*)^i \longrightarrow A \otimes_R J_R
\]
and, in turn, a well-defined cup product
\[ C(G, A \otimes \mathcal{F}_T(T)) \otimes_R C(G, \mathcal{F}_T(T^*)^i(\kappa)) \to C(G, A \otimes_R J_R(\kappa)), \]

which is a map of complexes of \( \Omega \otimes_R \Lambda^\circ\)-modules.

Note that, by definition, the adjoint maps (defined as in [Lim2, Lemma 2.2])
\[ \text{adj}(\pi): T^* \to \text{Hom}_R(T, J_R) \quad \text{and} \quad \text{adj}'(\pi): T \to \text{Hom}_R(T^*, J_R) \]
of \( \pi \) are quasi-isomorphisms, the first being simply the inclusion of complexes already defined. Since the terms of \( J_R \) are injective \( R \)-modules, it follows from Proposition 2.2.1 that the derived adjoint maps
\[ \text{adj}(\pi): T^* \to \text{RHom}_R(T, \omega_R) \quad \text{and} \quad \text{adj}'(\pi): T \to \text{RHom}_R(T^*, \omega_R) \]
are isomorphisms in \( D^b_{R,G}(\text{Mod}_R[G]) \), hence in \( D^b_{R,G}(\mathcal{F}_R,G) \), considering the restriction of \( \text{RHom}_R(-, -) \) to a bifunctor
\[ D^+(C^{R-R}_{R,G}) \times D^+(\text{Mod}_R) \to D^+(\mathcal{F}_R,G). \]

(see [Nek (3.5.9)]).

Though we shall not use it later, we feel it important to note that the derived adjoint maps of \( \pi \) are also isomorphisms. While this is easy enough to prove in the bounded below derived category \( D^+(\text{Mod}_{\Lambda^*}[G]) \) of abstract modules (in the case of \( \text{adj}(\pi) \)), we are interested in \( G \)-cohomology groups, so we want such an isomorphism in \( D^+(\mathcal{A}^*, G) \).

**Theorem 3.3.4.** For any bounded complexes \( T \) and \( T^* \) of objects in \( C_{R,G} \) such that \( T^* \) sits quasi-isomorphically as a subcomplex of the dual \( \text{Hom}_R(T, J_R) \), the derived adjoint maps
\[ \text{adj}(\pi): \mathcal{F}_T(T^*)^i \to \text{RHom}_{\Lambda,\text{cts}}(\mathcal{F}_T(T), \Lambda \otimes_R \omega_R) \]
\[ (\text{resp., } \text{adj}'(\pi): \mathcal{F}_T(T) \to \text{RHom}_{\Lambda,\text{cts}}(\mathcal{F}_T(T^*)^i, \Lambda \otimes_R \omega_R)) \]
are isomorphisms in \( D^+(\mathcal{A}^*, G) \) (resp., \( D^+(\mathcal{A}, G) \)). Moreover, the derived object \( \text{RHom}_{\Lambda,\text{cts}}(\mathcal{F}_T(T), \Lambda \otimes_R \omega_R) \) (resp., \( \text{RHom}_{\Lambda,\text{cts}}(\mathcal{F}_T(T^*)^i, \Lambda \otimes_R \omega_R) \)) can be represented by \( \text{Hom}_{\Lambda}(\mathcal{T}_T(T), \Lambda \otimes_R J_R) \) (resp., \( \text{Hom}_{\Lambda}(\mathcal{T}_T(T^*)^i, \Lambda \otimes_R J_R) \)).

**Proof.** Let \( X = \text{RHom}_{\Lambda,\text{cts}}(\mathcal{F}_T(T), \Lambda \otimes_R \omega_R) \). Since \( J_R \) is a complex of \( R \)-injectives and \( \chi \Lambda \) is flat over \( R \), Lemma 2.5.9 implies that the functor \( F \) given by
\[ \text{Hom}_{\Lambda,\text{cts}}(\Lambda \otimes_R T, \Lambda \otimes_R J_R): \text{Ch}^-(C_{R,G})^\circ \to \text{Ch}^+(\mathcal{A}^*, G) \]
is exact. In particular, if \( P \to T \) is a quasi-isomorphism with \( P \) a bounded above complex of projective objects in \( C_{R,G} \), then \( F(T) \to F(P) \) is a quasi-isomorphism. As \( \Lambda \otimes_R P \) is a complex of objects in \( C_{A,G} \) that are projective in \( C_{R,G} \), we then have that \( F(T) \) represents \( X \) by Proposition 2.5.8.
By Lemmas 2.4.2(b) and 2.5.7, the functor $F$ equals $\text{Hom}_\Lambda (\Lambda \chi \otimes_R -, \Lambda \otimes_R J_R)$ on $\text{Ch}^-(\mathcal{R}_R)^{\otimes}$. Therefore, $X$ is represented by $\text{Hom}_\Lambda (\mathcal{T}_R(T), \Lambda \otimes_R J_R)$ in $\mathcal{D}^+(\mathcal{I}_\Lambda, G)$. Finally, since the map $T^* \to \text{Hom}_R(T, J_R)$ is a quasi-isomorphism, the adjoint map of complexes $\chi \Lambda \otimes_R T^* \to \text{Hom}_\Lambda (\Lambda \chi \otimes_R T, \Lambda \otimes_R J_R)$ is a quasi-isomorphism of complexes of $\Lambda \circ\llbracket G\rrbracket$-modules by Lemma 2.2.3. Therefore, we have the result for $\text{adj}(\pi)$, and the proof for $\text{adj}'(\pi)$ is analogous.

4 Duality over $p$-adic Lie extensions

We now turn to arithmetic. Here, we fix the notation that we shall use throughout this section. To start, let $p$ be a prime. We let $F$ be a global field of characteristic not equal to $p$. Let $S$ be a finite set of primes of $F$ that, in the case that $F$ is a number field, contains all primes above $p$ and all real places. Let $S_f$ (resp., $S_R$) denote the set of finite places (resp., real places) in $S$. Let $G_{F,S}$ denote the Galois group of the maximal unramified outside $S$ extension of $F$. For a place $v$ of $F$, let $F_v$ denote the completion of $F$ at $v$, and let $G_v$ denote a fixed decomposition group for $v$ in the absolute Galois group of $F$.

We fix a $p$-adic Lie extension $F_{\infty}$ of $F$ that is unramified outside $S$, and we let $\Gamma$ denote its Galois group. We let $R$ denote a complete commutative local Noetherian ring with finite residue field of characteristic $p$, and we set $\Lambda = R[\Gamma]$. We take the homomorphism $\chi: G_{F,S} \to \Gamma$ of Section 3.1 to be restriction.

4.1 Iwasawa cohomology

We recall the following facts, all of which can all be found in [NSW, Chapters VII-VIII]. The $G_{F,S}$-cohomology groups of a finite $G_{F,S}$-module of $p$-power order are all finite. If $p$ is odd or $F$ has no real places, then $G_{F,S}$ has $p$-cohomological dimension at most 2 and so is $p$-cohomologically finite in the sense of Section 3.2. If $v$ is a nonarchimedean place of $F$, then $G_v$ has $p$-cohomological dimension equal to 2, and the $G_v$-cohomology groups of a finite $G_v$-module of $p$-power order are finite as well. Of course, the $G_v$-cohomology groups of a finite module are also finite for archimedean $v$, since $G_v$ is of order dividing 2 for such places.

Recall (e.g., from [Nek, (5.7.2)]) that, for any profinite ring $\Omega$, the (Tate) compactly supported $G_{F,S}$-cochain complex of a complex of objects $M$ in $\mathcal{C}_\Omega$ is defined as

$$C_{(\partial)}(G_{F,S}, M) = \text{Cone} \left( C(G_{F,S}, M) \to \bigoplus_{v \in S_f} C(G_v, M) \oplus \bigoplus_{v \in S_R} \widetilde{C}(G_v, M) \right)[-1],$$

where $\widetilde{C}(G_v, M)$ is the Tate cohomology complex of $G_v$-modules.
where $\hat{C}(G_v, M)$ is defined as in \cite[Section 3.4]{Lim2} and denotes the standard complete complex of Tate $G_v$-cochains for $M$.

We remark that, in Nekovář’s notation, $C_{(c)}(G_{F,S}, M)$ is denoted $\hat{C}_{(c)}(G_{F,S}, M)$. We use the notation of \cite{FK1}, where parentheses are used to distinguish the latter group from the compactly supported cochains $C_c(G_{F,S}, M)$, for which one uses the usual cohomology groups at real places. For archimedean $v$, we will abuse notation and use $RΓ(G_v, M)$ to denote the derived object of the Tate cochains $\hat{C}(G_v, M)$. These cochains may as well be taken to be zero for complex places or for real places if $p$ is odd, $RΓ(G_v, M)$ being a zero object in the derived category.

We denote the derived object corresponding to $C_{(c)}(G_{F,S}, M)$ by $RΓ_{(c)}(G_{F,S}, M)$ and its $i$th cohomology group by $H^i_{(c)}(G_{F,S}, M)$. By definition, we have an exact triangle

$$RΓ_{(c)}(G_{F,S}, M) \rightarrow RΓ(G_{F,S}, M) \rightarrow \bigoplus_{v \in S} RΓ(G_v, M)$$

in $\mathcal{D}(\text{Mod}_\Lambda)$. The results of and methods used in Section 3.1 allow us to prove the following descent result for such an exact triangle with induced coefficients.

**Proposition 4.1.1.** Let $Γ' = \text{Gal}(F'_\infty/F)$ be a quotient of $Γ$ by a closed normal subgroup, and set $Λ' = R[Γ/Γ'][Γ]$. Let $T$ be a bounded above complex of objects in $C_{R,G_{F,S}}$. Suppose that at least one of the following holds: (i) $p$ is odd, (ii) $F'_\infty$ has no real places, or (iii) $T$ is bounded and $F'_\infty$ has no real places that become complex in $F_\infty$. Then we have an isomorphism of exact triangles

\[ \Lambda' \otimes^L RΓ_{(c)}(G_{F,S}, \mathcal{F}_T'(T)) \cong RΓ_{(c)}(G_{F,S}, \mathcal{F}_{Γ'}(T)) \]

\[ \Lambda' \otimes^L RΓ(G_{F,S}, \mathcal{F}_T'(T)) \cong RΓ(G_{F,S}, \mathcal{F}_{Γ'}(T)) \]

\[ \Lambda' \otimes^L \bigoplus_{v \in S} RΓ(G_v, \mathcal{F}_T'(T)) \cong \bigoplus_{v \in S} RΓ(G_v, \mathcal{F}_{Γ'}(T)) \]

in $\mathcal{D}(\text{Mod}_Λ)$.

**Proof.** We need only show that the lower and upper horizontal morphisms are isomorphisms. The upper morphism exists and is an isomorphism for $T$ bounded above without additional assumption. That is, recall that the compactly supported cohomology groups of a module vanish in dimension greater than $3$ \cite[Lemma 5.7.3]{Nek}. The hypercohomology spectral sequence for compactly supported cohomology therefore converges for bounded above complexes, yielding the existence of a functor

$$RΓ_{(c)}(G_{F,S}, -): \mathcal{D}^-(C_{Λ,G_{F,S}}) \rightarrow \mathcal{D}^-(\text{Mod}_Λ).$$

\[ \text{We write an exact triangle } A \rightarrow B \rightarrow C \rightarrow A[1] \text{ more compactly as } A \rightarrow B \rightarrow C \text{ throughout.} \]
The analogous result to Proposition \[4.1.3\] then holds by the original argument (in the case that (1) holds and \(Y\) is bounded above). That the upper morphism exists and is an isomorphism follows immediately as in Theorem \[3.1.8\]. The next proposition shows in particular that if \(\hat{\Gamma}(\mathbb{L}), S_f\) then holds with “bounded above” removed if we suppose that the kernel of \(\Gamma \rightarrow \Gamma'\) has no elements of order \(p\). This follows quickly if \(p\) is odd or \(F\) has no real places, but it requires some work in the remaining case that \(F_{\infty}^p\) has no real places but \(D\) does. We omit this for purposes of brevity.

The analogous result to Proposition \[4.1.3\] then holds by the original argument (in the case that (1) holds and \(Y\) is bounded above). That the upper morphism exists and is an isomorphism follows immediately as in Theorem \[3.1.8\]. The analogous result to Proposition \[3.1.3\] then holds by the original argument (in the case that (1) holds and \(Y\) is bounded above). That the upper morphism exists and is an isomorphism follows immediately as in Theorem \[3.1.8\]. For a real place \(v\) of \(F\), the functor \(\Gamma(\mathbb{L}, -)\) is well-defined only on the bounded derived category. However, if \(v\) becomes complex in \(F_{\infty}^p\), then the relevant hypercohomology spectral sequence implies that the composite functor \(\Pi(\mathbb{L}, \mathbb{F})\) is both well-defined and zero on \(D(\mathbb{L})\). So, the \(v\)-summand of the lower horizontal morphism is trivially an isomorphism. If \(v\) splits completely in \(F_{\infty}^p\), then the modules \(\Lambda\) and \(\chi\Lambda\) have trivial \(G_v\)-actions, so we have isomorphisms \(\mathbb{F}(T) \cong \Lambda \otimes_R T\) and \(\mathbb{F}(T)^* \cong \Lambda \otimes_R T^*\) of complexes in \(C_{\Lambda, G_v}\) and \(C_{\Lambda', G_v}\), respectively. Since \(G_v\) is finite, the terms of \(\mathbb{C}(\mathbb{L}, \mathbb{M})\) for a \(G_v\)-module \(M\) are each naturally isomorphic to a finite direct sum of copies of \(M\). With these identifications, the canonical map

\[
\Lambda \otimes_R \mathbb{C}(\mathbb{L}) \rightarrow \mathbb{C}(\mathbb{L}, \Lambda \otimes_R T)
\]

agrees with the identity map, so is an isomorphism. Of course, we have the corresponding result for \(\Lambda\), and the isomorphism

\[
\Lambda' \otimes_R (\Lambda \otimes_R \mathbb{C}(\mathbb{L})) \rightarrow \Lambda' \otimes_R \mathbb{C}(\mathbb{L})
\]

in \(D(\mathbb{M})\) provides the \(v\)-summand of the lower isomorphism. □

**Remark 4.1.2.** Proposition \[4.1.1\] holds with “bounded above” removed if we suppose that the kernel of \(\Gamma \rightarrow \Gamma'\) has no elements of order \(p\). This follows quickly if \(p\) is odd or \(F\) has no real places, but it requires some work in the remaining case that \(F_{\infty}^p\) has no real places but \(D\) does. We omit this for purposes of brevity.

The next proposition shows in particular that if \(T\) is a bounded complex of objects of \(C_{R, G_{\infty}}\-\mathbb{R}\), then the global, local, and compactly supported cohomology groups of \(\mathbb{F}(T)\) are finitely generated \(\Lambda\)-modules. (Here, we implicitly identify cochain complexes with their quasi-isomorphic truncations in the derived category.)

**Proposition 4.1.3.** Let \(T\) be a complex of objects of \(C_{R, G_{\infty}}\-\mathbb{R}\).

(a) The complex \(\mathbb{R}\Gamma(G, \mathbb{F}(\mathbb{S}))\) lies in \(D_{\mathbb{L}}(\mathbb{M})\) if \(F_{\infty}^p\) has no real places or \(p\) is odd and in \(D_{\mathbb{L}}(\mathbb{M})\) if \(T\) is bounded above.

(b) The complex \(\mathbb{R}\Gamma(G, \mathbb{F}(\mathbb{S}))\) for \(v \in S_f\) lies in \(D_{\mathbb{L}}(\mathbb{M})\) if \(F_{\infty}^p\) has no real places or \(p\) is odd and in \(D_{\mathbb{L}}(\mathbb{M})\) if \(T\) is bounded below.

(c) If \(T\) is bounded and \(\mathbb{R}\Gamma(G, \mathbb{F}(\mathbb{S}))\) lie in \(D_{\mathbb{L}}(\mathbb{M})\) if \(T\) is bounded above.

\(\mathbb{R}\Gamma(G, \mathbb{F}(\mathbb{S}))\) and \(\mathbb{R}\Gamma(G, \mathbb{F}(\mathbb{S}))\) lie in \(D_{\mathbb{L}}(\mathbb{M})\).
(d) For $v \in S_f$, the complex $R\Gamma(G_v, \mathcal{F}_T(T))$ lies in $D_{\Lambda,-}(\text{Mod}_\Lambda)$ and in $D^b_{\Lambda,-}(\text{Mod}_\Lambda)$ if $T$ is bounded.

(e) The complex $R\Gamma(G_v, \mathcal{F}_T(T))$ for $v \in S_R$ lies in $D_{\Lambda,-}(\text{Mod}_\Lambda)$ if $T$ is bounded.

Proof. For real $v$, any $i \in \mathbb{Z}$ and $T$ concentrated in degree 0, the Tate cohomology group $\check{H}^i(G_v, \mathcal{F}_T(T))$ is a 2-torsion subquotient of $\mathcal{F}_T(T)$, as $G_v$ has order 2. Hence, it is finitely generated over $\Lambda$ as $\mathcal{F}_T(T)$ is. The hypercohomology spectral sequence allows one to pass to the case of a bounded complex $T$, and therefore $R\Gamma(G_v, \mathcal{F}_T(T))$ lies in $D_{\Lambda,-}(\text{Mod}_\Lambda)$, hence (e). Recall also that $R\Gamma(G_v, \mathcal{F}_T(T))$ is a zero object for all complexes $T$ if $v$ extends to a complex place of $F_\infty$.

If $v \in S$ is nonarchimedean, then $G_v$ is $p$-cohomologically finite by our above remarks, and hence Theorem 3.2.4 implies that $R\Gamma(G_v, \mathcal{F}_T(T))$ lies in $D_{\Lambda,-}(\text{Mod}_\Lambda)$. In the case that $p$ is odd or $F_\infty$ has no real places, Theorem 3.2.4 again implies that $R\Gamma(G_v, \mathcal{F}_T(T))$ lies in $D_{\Lambda,-}(\text{Mod}_\Lambda)$. (For this, note that if $p = 2$ and $F$ has a real place that becomes complex in $F_\infty$, it will already have become complex in any extension with Galois group $\Gamma/\Gamma_0$, where $\Gamma_0$ is an open uniform pro-$p$ subgroup of $\Gamma$.) In this case, it follows from the above-mentioned exact triangle that $R\Gamma(G_v, \mathcal{F}_T(T))$ is in $D_{\Lambda,-}(\text{Mod}_\Lambda)$.

Finally, if $T$ is bounded, then clearly all of the above complexes will additionally lie in the bounded derived category. In particular, we have (c) and (d) and part of each of (a) and (b).

The analogue of Theorem 3.2.4 for compactly supported cohomology holds for bounded above $T$ since $H^i(G_{F,S}, \mathcal{F}_T(T))$ vanishes for sufficiently large $i$. The proof is essentially identical but uses the semilocal version of Shapiro's lemma [Nek 8.5.3.2] in the first step and the relevant hypercohomology spectral sequence in the last. Thus we have (a).

Finally, if $T$ is concentrated in degree 0, the exact triangle tells us that $H^i(G_{F,S}, \mathcal{F}_T(T))$ is finitely generated over $\mathcal{F}_T(T)$ for sufficiently large $i$. Thus, we are still able to perform the inductive step in the proof of Theorem 3.2.4 to obtain that $R\Gamma(G_{F,S}, \mathcal{F}_T(T))$ sits in $D^+_{\Lambda,-}(\text{Mod}_\Lambda)$ for such $T$, and then for bounded below $T$ via the hypercohomology spectral sequence. Thus, we have (b).

Remark 4.1.4. Part (d) of Proposition 4.1.3 makes sense and holds more generally for any complex $T$ in $C^{R,-1}_{\Lambda,\text{Mod}_\Lambda}$, as $G_v$-action through the composite with the canonical map $G_v \to G_{F,S}$.

Remark 4.1.5. We may also consider the setting in which we take $F$ itself to be a nonarchimedean local field of characteristic not equal to $p$. We then let $G_F$ be its absolute Galois group, let $\Gamma$ denote the Galois group of a $p$-adic Lie extension of $F$, and as before, set $\Lambda = \mathbb{F}_p[\Gamma]$. In this case, we obtain immediately from Theorem 3.2.4 that the cohomology groups $H^j(G_F, \mathcal{F}_T(T))$ are finitely generated $\Lambda$-modules for all $j$ and any complex of objects of $T$ of

Documenta Mathematica 18 (2013) 621–678
for any complex $T$ of objects in $\mathcal{C}_{R,G_F}^{R\text{-ft}}$.

4.2 Duality over local fields

In this subsection, we will state a version of Tate duality for $\Gamma$-induced modules with $\Lambda \otimes R \omega_R$ for a dualizing complex $\omega_R$ replacing $\mathbb{Q}_p/\mathbb{Z}_p$. Fix a nonarchimedean prime $v \in S$. We continue to suppose that $\Gamma$ is a compact $p$-adic Lie group that is a quotient of $G_{F,S}$ defining an extension $F_\infty$, though as we remark later, we could just as well assume it to be a quotient of $G_v$. Let $T$ be a bounded complex of objects in $\mathcal{C}_{R,G_F}^{R\text{-ft}}$. As before, we let $J_R$ denote a complex of injective $R$-modules that represents $\omega_R$, and we let $T^*$ be a quasi-isomorphic subcomplex of $\text{Hom}_R(T,J_R)$ consisting of objects of $\mathcal{C}_{R,G_F}^{R\text{-ft}}$.

The cup product of Lemma 4.3.9 yields a map

$$C(G_v, \mathcal{F}_T(T)) \otimes_R C(G_v, \mathcal{F}_T(T^*)^i(1)) \longrightarrow \tau_{\geq 2}^{I_I} C(G_v, \Lambda \otimes_R J_R(1))$$

of $\Lambda \otimes_R \Lambda^\circ$-modules. Taking adjoints, we have the following maps of complexes of $\Lambda$-modules and $\Lambda^\circ$-modules, respectively:

$$C(G_v, \mathcal{F}_T(T)) \longrightarrow \text{Hom}_\Lambda \left( C(G_v, \mathcal{F}_T(T^*)^i(1)), \tau_{\geq 2}^{I_I} C(G_v, \Lambda \otimes_R J_R(1)) \right),$$

$$C(G_v, \mathcal{F}_T(T^*)^i(1)) \longrightarrow \text{Hom}_\Lambda \left( C(G_v, \mathcal{F}_T(T)), \tau_{\geq 2}^{I_I} C(G_v, \Lambda \otimes_R J_R(1)) \right).$$

From now on, we use $M^\circ$ to denote the Pontryagin dual of a locally compact abelian group $M$. We have the following analogue of [Nek] (5.2.1).

**Lemma 4.2.1.** Let $A$ be a bounded complex in $\mathcal{C}_{\Lambda,\Lambda}^{\Lambda^\circ -$ft with terms that are flat as $R$-modules. Then there exists a quasi-isomorphism

$$q_A: (A \otimes_R J_R)[-2] \longrightarrow \tau_{\geq 2}^{I_I} C(G_v, A \otimes_R J_R(1)),$$

natural in $A$, of chain complexes of $\Lambda \otimes_R \Lambda^\circ$-modules.

**Proof.** We first note that if $M$ is any finitely generated $R$-module with a trivial action of $G_v$, then Tate local duality as in [Lim2] Theorem 4.1.2 yields isomorphisms

$$H^2(G_v, A \otimes_R M(1)) \cong H^0(G_v, (A \otimes_R M)^\circ)^\circ = A \otimes_R M,$$

of $\Lambda \otimes_R \Lambda^\circ$-modules. Now suppose that $M$ is any (ind-admissible) $R[G_v]$-module with trivial $G_v$-action, and write $M = \bigcup M_i$, where the $M_i$ are finitely generated $R$-submodules of $M$. Since the terms of $A$ are $R$-flat, $A^i \otimes_R M$ is the union of the $A^i \otimes_R M_i$ for any $i \in \mathbb{Z}$, so

$$H^2(G_v, A \otimes_R M(1)) \cong \lim_{\longrightarrow} H^2(G_v, A \otimes_R M_i(1)) \cong \lim_{\longrightarrow} A \otimes_R M_i \cong A \otimes_R M.$$
As $G_v$ is of $p$-cohomological dimension 2, we therefore have a quasi-isomorphism

$$A \otimes_R M[-2] \to \tau_{\geq 2} \mathcal{C}(G_v, A \otimes_R M(1)),$$

of complexes of $\Lambda \otimes_R \Lambda^\circ$-modules. The case of a bounded complex $\mathcal{M}$ of ind-admissible $R$-modules, e.g. $M = J_R$, then follows easily. Naturality is immediate from the construction.

Combining Lemma 4.2.1 for $A = \Lambda$ with the morphisms constructed above and passing to the derived category, we obtain morphisms as in the following theorem.

**Theorem 4.2.2.** Let $T$ be a bounded complex in $\mathcal{C}_{R,G_v}$. Then the morphisms

$$\mathcal{R}\Gamma(G_v, \mathcal{F}_T(T)) \to \mathcal{R}\text{Hom}_\Lambda\left(\mathcal{R}\Gamma(G_v, \mathcal{F}_T(T^\ast)(1)), \Lambda \otimes^I_R \omega_R\right)[-2]
\mathcal{R}\Gamma(G_v, \mathcal{F}_T(T^\ast)(1)) \to \mathcal{R}\text{Hom}_\Lambda\left(\mathcal{R}\Gamma(G_v, \mathcal{F}_T(T)), \Lambda \otimes^I_R \omega_R\right)[-2]$$

in $\mathcal{D}_{\Lambda-R}(\text{Mod}_\Lambda)$ and $\mathcal{D}_{\Lambda-R}(\text{Mod}^\ast_{\Lambda})$, respectively, are isomorphisms.

Over the course of the next two subsections, we will show that the first of the morphisms of Theorem 4.2.2 is an isomorphism. The proof that the second is an isomorphism is completely analogous. By an argument similar to that in [Nek, Lemma 5.2.5], it suffices to prove the theorem for a particular translate of the dualizing complex. In view of this, we will assume that our choice of the dualizing complex satisfies [Nek, (2.5)(i)] throughout the next two subsections.

**Remark 4.2.3.** In the setting that $F$ is a nonarchimedean local field of characteristic not equal to $p$, that $F_\infty$ is any $p$-adic Lie extension of $F$, and that $T$ is a bounded complex of objects in $\mathcal{C}_{R,G_F}$, the argument we are about to describe also carries over as in Remark 4.1.5 to prove the direct analogue of Theorem 4.2.2 with $G_v$ replaced by $G_F$.

### 4.3 Change of rings

Recall that $R$ is a complete commutative local Noetherian ring with maximal ideal $m$ and finite residue field $k$. In this subsection, we shall show that it suffices to prove Theorem 4.2.2 for any complete commutative local Noetherian ring $S$ that has $R$ as a quotient. (In this subsection only, $S$ denotes such a ring, rather than the set of primes chosen above, which is used only implicitly.)

We suppose given a surjection $\psi: S \to R$, which necessarily induces an isomorphism on residue fields. We use $m_S$ to denote the maximal ideal of $S$, and we set

$$d = \dim_k m_S/m_S^2 - \dim_k m/m^2.$$

Note that if $A$ is any complex of $S$-modules, then $\text{Hom}_S(R, A)$ is isomorphic to the subcomplex of $A$ with terms the torsion submodules under $\ker\psi$. In
particular, if $B$ is a complex of $R$-modules, then the resulting inclusion map induces an isomorphism

$$\text{Hom}_R(B, \text{Hom}_S(R, A)) \xrightarrow{\sim} \text{Hom}_S(B, A),$$

as is easy enough to see by the usual adjointness principle. In particular, we have

$$\text{Hom}_R(B, R^\vee) \xrightarrow{\sim} \text{Hom}_S(B, S^\vee).$$

With this comparison of Matlis duals with respect to $R$ and $S$ in hand, we now compare Grothendieck duals with respect to these rings (see also [Har2]). For this, we choose particular dualizing complexes $J_R$ and $J_S$ of injectives as follows. Let $\bar{x}_1, \ldots, \bar{x}_r \in \mathfrak{m}$ with images forming a $k$-basis of $\mathfrak{m}/\mathfrak{m}^2$. Recall (cf. [Nek, Section 0.4]) that we may take $J_R$ to be the Matlis dual of $C_R[r]$, where $C_R$ is defined to be the complex

$$[R \to \bigoplus_i R_{\bar{x}_i} \to \bigoplus_{i<j} R_{\bar{x}_i \bar{x}_j} \to \cdots \to R_{\bar{x}_1 \cdots \bar{x}_r}]$$

in degrees $[0, r]$, with the usual Čech differentials, which is to say that

$$J_R = \text{Hom}_R(C_R[r], R^\vee).$$

Note that $J_R$ is a complex of $R$-injectives by the $R$-flatness of the terms of $C_R$ and the $R$-injectivity of $R^\vee$. We lift $\bar{x}_1, \ldots, \bar{x}_r$ to elements $x_1, \ldots, x_r$ of $\mathfrak{m}_S$ and extend to a sequence $x_1, \ldots, x_s$ such that the images of $x_1, \ldots, x_s$ form a basis of $\mathfrak{m}_S/\mathfrak{m}_S^2$ and the elements $x_{r+1}, \ldots, x_s$ map trivially to $\mathfrak{m}/\mathfrak{m}^2$. Modifying each $x_i$ with $i > r$ by an element of $\mathfrak{m}_S^2$ if necessary, we may choose these elements so that they in fact map trivially to $\mathfrak{m}$. We use this sequence to define $C_S$, and we set $J_S = \text{Hom}_S(C_S[s], S^\vee)$.

**Lemma 4.3.1.** Let $T$ be a bounded complex in $C_{R,G}^{0}$, which we view also as a complex in $C_{S,G}^{-r}$ via $\psi$. Then $\psi$ induces a natural map $J_R \to J_S[d]$ and in turn an isomorphism

$$\text{Hom}_R(T, J_R) \xrightarrow{\sim} \text{Hom}_S(T, J_S)[d]$$

of complexes in $\mathcal{A}_{S,G}$. 

**Proof.** The natural map $C_S \to C_R$ factors through an isomorphism $R \otimes_S C_S \xrightarrow{\sim} C_R$. This induces an isomorphism

$$J_R \xrightarrow{\sim} \text{Hom}_S(R, J_S)[d],$$

which is given by the following composition of isomorphisms

$$\text{Hom}_R(C_R[r], R^\vee) \xrightarrow{\sim} \text{Hom}_S(C_R[r], S^\vee) \xrightarrow{\sim} \text{Hom}_S(R \otimes_S C_S[r], S^\vee)$$

$$\xrightarrow{\sim} \text{Hom}_S(R, \text{Hom}_S(C_S[r], S^\vee)) \xrightarrow{\sim} \text{Hom}_S(R, \text{Hom}_S(C_S[s], S^\vee))[d],$$

\[\text{Documenta Mathematica} 18 (2013) 621–678\]
where the latter natural map is defined as in [Nek (1.2.15)] (noting [Nek
(1.2.5)]). The result then follows from the isomorphisms

\[ \text{Hom}_R(T, J_R) \sim \text{Hom}_R(T, \text{Hom}_S(R, J_S))[d] \sim \text{Hom}_S(T, J_S)[d]. \]

We now proceed to the reductive step.

**Proposition 4.3.2.** Let \( T \) be a bounded complex in \( \mathcal{C}^{R-\text{ft}}_{R, G_v} \). Setting \( \Omega = S[\Gamma] \), there is a commutative diagram of natural morphisms

\[
\begin{array}{ccc}
\mathbf{R}\Gamma(G_v, \mathcal{F}(T)) & \longrightarrow & \mathbf{R}\text{Hom}_{\Lambda^c}(\mathbf{R}\Gamma(G_v, \mathcal{F}(T)^{\ast}(1)), \Lambda \otimes_R \omega_R)[-2] \\
\downarrow \iota & & \downarrow \iota \\
\mathbf{R}\Gamma(G_v, \Omega \otimes_S T) & \longrightarrow & \mathbf{R}\text{Hom}_{\Omega^c}(\mathbf{R}\Gamma(G_v, \Omega \otimes_S T)^{\ast}(1), \Omega \otimes_S \omega_S)[d] [-2]
\end{array}
\]

in which the horizontal morphisms are as in Theorem 4.2.2 and the vertical arrows are isomorphisms in \( \mathbf{D}(\text{Mod}_\Omega) \). In particular, Theorem 4.2.2 holds for \( R \) if it holds for \( S \).

**Proof.** Note that we have

\( \Omega \otimes_S T \cong \lambda \otimes_R T \) (resp., \( \Omega \otimes_S T^\ast \cong \lambda \otimes_R T^\ast \))

so \( \mathbf{R}\Gamma(G_v, \mathcal{F}(T)) \) (resp., \( \mathbf{R}\Gamma(G_v, \mathcal{F}(T)^{\ast}(1)) \)) is the same complex for \( R \) and for \( S \). By Lemma 4.3.1 and employing the \( S \)-flatness of \( \Omega \) in applying Lemma 2.1.4, we have canonical isomorphisms

\[ \lambda \otimes_R J_R \sim \Omega \otimes_S J_R \sim \Omega \otimes_S \text{Hom}_S(R, J_S)[d] \sim \text{Hom}_S(R, \Omega \otimes_S J_S)[d], \]

of complexes of \( \Omega^c \otimes_R R \cong \mathcal{A}^c \)-modules, and the composition of the composite isomorphism with the natural inclusion

\[ \text{Hom}_S(R, \Omega \otimes_S J_S)[d] \longrightarrow \Omega \otimes_S J_S[d] \]

induces the right-hand vertical map in the proposition. That the diagram commutes then follows directly from the definition of the cup product in Lemma 3.3.3.

Let us fix a quasi-isomorphism \( \iota: \Omega \otimes_S J_S \rightarrow K \), where \( K \) is a bounded below complex of injective \( \Omega^c \)-modules. We check that the map

\[ \iota_R: \text{Hom}_S(R, \Omega \otimes_S J_S) \longrightarrow \text{Hom}_S(R, K) \]

induced by \( \iota \) is a quasi-isomorphism, which implies that \( \text{Hom}_S(R, \Omega \otimes_S J_S) \) represents \( \mathbf{R}\text{Hom}_S(R, \Omega \otimes_S \omega_S) \) in \( \mathbf{D}(\text{Mod}_{\Lambda^c}) \). Let \( \varepsilon: P \rightarrow R \) be a resolution of
R by a complex $P$ of finitely generated free $S$-modules. We have a commutative diagram

$$
\begin{array}{cccccc}
\Omega \otimes_S \text{Hom}_S(R, J) & \overset{\phi_R}{\longrightarrow} & \text{Hom}_S(R, \Omega \otimes_S J) & \overset{\psi_R}{\longrightarrow} & \text{Hom}_\Omega^\circ(\Omega \otimes_S R, K) \\
\downarrow \epsilon \otimes_S \iota & & \downarrow \iota & & \downarrow (\iota \otimes_S) K \\
\Omega \otimes_S \text{Hom}_S(P, J) & \overset{\phi_P}{\longrightarrow} & \text{Hom}_S(P, \Omega \otimes_S J) & \overset{\psi_P}{\longrightarrow} & \text{Hom}_\Omega^\circ(\Omega \otimes_S P, K)
\end{array}
$$

in which the vertical maps are all induced by $\epsilon$. Moreover, note that the upper horizontal morphisms are of complexes of $\Lambda^\circ$-modules and the others are of complexes of $\Omega^\circ$-modules. The maps $\phi_P$ and $\phi_R$ are isomorphisms, and the map $\iota$ is a quasi-isomorphism by the $\Lambda^\circ$-injectivity of $J$ and the $\Lambda^\circ$-flatness of $\Omega$, so $\epsilon_{\Omega \otimes_S, P}$ is also a quasi-isomorphism. The maps $\psi_R$ and $\psi_P$ are isomorphisms by the usual adjointness of $\text{Hom}$ and the tensor product, and the map $(\iota \otimes_S) K$ is a quasi-isomorphism by the $\Omega^\circ$-injectivity of $K$, so $\epsilon_K$ is a quasi-isomorphism as well. Finally, the map $\iota$ is a quasi-isomorphism by the $\Lambda^\circ$-projectivity of $P$, and it follows that $\iota_R$ is a quasi-isomorphism.

To finish the proof, we need only show that the morphism

$$\text{RHom}_{\Lambda^\circ}(X, \text{RHom}_S(R, \Omega \otimes_S \omega)) \longrightarrow \text{RHom}_{\Omega^\circ}(X, \Omega \otimes_S \omega_S)$$

is an isomorphism for $X = C(G_v, \mathcal{F}_T(T^*)^!(1))$. It is easy to see that $\text{Hom}_S(R, K)$ is a complex of injective $\Lambda^\circ$-modules. Moreover, every $\Omega^\circ$-homomorphism from the complex $X$ of $\Lambda^\circ$-modules to $K$ must factor through $\text{Hom}_\Omega^\circ(\Lambda, K) \cong \text{Hom}_\Omega^\circ(\Omega \otimes_S R, K) \cong \text{Hom}_S(R, K)$ of $K$, so the map

$$\text{Hom}_{\Lambda^\circ}(X, \text{Hom}_S(R, K)) \longrightarrow \text{Hom}_{\Omega^\circ}(X, K)$$

induced by inclusion is an isomorphism, as desired.

4.4 Duality over flat $\mathbb{Z}_p$-algebras

In this subsection, we will prove Theorem 4.2.2. As remarked in the proof of Proposition 4.3.1, every complete commutative Noetherian local ring with finite residue field of characteristic $p$ is a quotient of a power series ring in finitely many variables over an unramified extension of $\mathbb{Z}_p$. Proposition 4.3.2 then allows us to reduce Theorem 4.2.2 to the case of such power series rings. We therefore can and do assume that $R$ is $\mathbb{Z}_p$-flat throughout this subsection.

We will require a bit more general of a derived adjoint map than the one we wish to prove is an isomorphism. The construction is found in the following easy lemma.

**Lemma 4.4.1.** Let $A$ be a bounded complex of $R$-flat objects in $\mathcal{C}^{\Lambda^\circ\text{-}\otimes_R}_{\Lambda\text{-}}$. Then we have a morphism

$$\text{RHom}(G_v, A \otimes_\Lambda \mathcal{F}_T(T)) \longrightarrow \text{RHom}_{\Lambda^\circ}(\text{RHom}(G_v, \mathcal{F}_T(T^*)^!(1)), A \otimes_R \omega_R)[{-2}]$$
in $\mathbf{D}(\text{Mod}_\Lambda)$ that is natural in the complex $A$.

Proof. This is simply the derived adjoint of the composition of the cup product in Lemma 3.3.3 with the map to the truncation $\tau_{\geq 2}^1 C(G_v, A \otimes_R J_R(1))$, which is quasi-isomorphic to $(A \otimes_R J_R)[-2]$ by Lemma 4.2.1. Naturality is immediate. □

We will mostly be interested in complexes of length 2, so we introduce the following notation. Suppose that $B$ is an object in $C_{\Lambda^0, \Lambda}$ and that $A$ is a subobject of $B$, which is to say that it is a closed $\Lambda \hat{\otimes}_R \Lambda^0$-submodule with the subspace topology. Then for any bounded complex $T$ of objects in $C_{R, G_v}$, we define a complex $F_{B/A}(T) = [A \rightarrow B] \otimes_{\Lambda} F_T(T)$, of objects in $C_{\Lambda, G_v}$, where $A$ and $B$ are in degree -1 and 0 respectively.

Let $I = I(\Gamma)$ denote the augmentation ideal of $\Lambda$. We then have the following lemmas. Recall for the first that we assume that $R$ is $\mathbb{Z}_p$-flat in this subsection.

Lemma 4.4.2. The following statements hold for any $n \geq 0$.

(a) The ideal $I^n$ is a flat $R$-module.

(b) The module $I^n/I^{n+1}$ is finitely generated and of finite projective dimension over $R$.

Proof. (a) Suppose first that $\Gamma$ is finite, and let $I$ denote the augmentation ideal in $\mathbb{Z}_p[\Gamma]$. As $\mathbb{Z}_p[\Gamma]$ is finitely generated and free over $\mathbb{Z}_p$, so is $I^n$. Since $R$ is $\mathbb{Z}_p$-flat, the natural surjection $R \otimes_{\mathbb{Z}_p} I^n \rightarrow I^n$ is an isomorphism, and therefore $I^n$ is free over $R$.

In the general case, $\Gamma \cong \lim_{\leftarrow} \Gamma'$, where $\Gamma'$ runs over the Galois groups of the finite Galois extensions of $F$ in $F_\infty$, and $I^n$ is the inverse limit of the $n$th powers of the augmentation ideals $I(\Gamma')$ of the $R[\Gamma']$. As $I(\Gamma')^n \cong I^n \otimes_R R[\Gamma']$, an application of Lemma 2.4.2 yields an isomorphism

$$I^n \otimes_R B \xrightarrow{\sim} \lim_{\Gamma'} (I(\Gamma')^n \otimes_R B)$$

for any ideal $B$ of $R$. The left exactness of the inverse limit and the $R$-flatness of $I(\Gamma')^n$ then imply that the canonical map $I^n \otimes_R B \rightarrow I^n$ is an injection, proving the flatness of $I^n$.

(b) Let $I$ denote the augmentation ideal in $\mathbb{Z}_p[\Gamma]$. For each $n$, the composition

$$R \otimes_{\mathbb{Z}_p} I^n \rightarrow R \otimes_{\mathbb{Z}_p} \mathbb{Z}_p[\Gamma] \rightarrow R[\Gamma]$$

induces a surjection $R \otimes_{\mathbb{Z}_p} I^n \rightarrow I^n$ that fits into the following commutative diagram with exact rows:

$$\begin{array}{ccc}
R \otimes_{\mathbb{Z}_p} I^{n+1} & \rightarrow & R \otimes_{\mathbb{Z}_p} I^n \rightarrow R \otimes_{\mathbb{Z}_p} (I^n/I^{n+1}) \rightarrow 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & I^{n+1} & \rightarrow & I^n & \rightarrow & I^n/I^{n+1} & \rightarrow & 0.
\end{array}$$

Documenta Mathematica 18 (2013) 621–678
Since the two vertical maps on the left are surjections, so is the one on the right. Note that $I^n/I^{n+1}$ is a quotient of $\mathbb{Z}_p$-module. Therefore, the existence of the above surjection implies that $I^n/I^{n+1}$ is finitely generated over $R$. To see that the last assertion holds, we note that it follows from (a) that $I^n/I^{n+1}$ has finite flat dimension. Since flat dimension coincides with projective dimension for every finitely generated module over a Noetherian ring (see [Wei, Proposition 4.1.5]), we have our assertion.

**Lemma 4.4.3.** Let $T$ be a bounded complex of objects in $\mathcal{C}_{R,G_\Lambda}^{\mathbb{N}-f}$. Then we have a quasi-isomorphism

$$\text{Cone}\left(\mathcal{F}_{I^n/I^{n+1}}(T) \longrightarrow \mathcal{F}_{\Lambda/I^{n+1}}(T)\right) \sim \mathcal{F}_{\Lambda/I^n}(T)$$

of complexes in $\mathcal{C}_{\Lambda,G_\Lambda}^{\mathbb{N}-f}$. Moreover, we have an exact triangle

$$I^n/I^{n+1} \otimes_R \omega_R \longrightarrow \Lambda/I^n \otimes_R \omega_R \longrightarrow \Lambda/I^n \otimes \Lambda$$

in $D^b(\text{Mod}_{\Lambda \otimes_R \Lambda})$.

**Proof.** Since the powers of $I$ are $R$-flat by Lemma 4.4.2(a), it suffices in both cases to show that there is a quasi-isomorphism

$$\text{Cone}\left([I^{n+1} \rightarrow I^n] \longrightarrow [I^{n+1} \rightarrow \Lambda]\right) \sim [I^n \rightarrow \Lambda].$$

Note that the latter cone is precisely the complex

$$I^{n+1} \xrightarrow{f} I^{n+1} \oplus I^n \xrightarrow{g} \Lambda,$$

where $f(x) = (x, -x)$ and $g(x, y) = x + y$ for $x \in I^{n+1}$ and $y \in I^n$. One can now easily check that the diagram

$$\begin{array}{c}
I^{n+1} \xrightarrow{f} I^{n+1} \oplus I^n \xrightarrow{g} \Lambda \\
\downarrow \quad \downarrow \nu \quad \downarrow \nu \\
0 \xrightarrow{} I^n \xrightarrow{} \Lambda
\end{array}$$

commutes, where $\nu$ is given by $\nu(x, y) = x + y$ for $x \in I^{n+1}$ and $y \in I^n$, and the vertical maps induce isomorphisms on cohomology. We are now able to prove the following proposition, which is an important ingredient in the proof of Theorem 4.2.2.
Lemma 4.4.4. Let $T$ be a bounded complex of objects in $\mathcal{C}_{\Lambda,G}$. Then we have the following isomorphisms

\[
\begin{array}{c}
\text{Proof.}\quad \text{By Lemma 4.4.2(a), we see that} \quad I^n/I^{n+1} \otimes_R \omega_R \text{ and } \Lambda/I^n \otimes_R \omega_R \text{ are represented by } [I^{n+1} \to I^n] \otimes_R J_R \text{ and } [I^n \to \Lambda] \otimes_R J_R \text{ respectively. Therefore, the commutativity of the diagram in the proposition follows from the naturality in Lemma 4.4.1. By Lemma 4.4.3 both columns are exact triangles.}
\end{array}
\]

We now describe the idea of the proof of Theorem 4.2.2. We shall first prove that the morphism

\[
\text{Proposition 4.4.4 is a quasi-isomorphism, so is the third one. Therefore, by an inductive argument, we are reduced to showing that the morphism}
\]

\[
\begin{array}{c}
\text{is an isomorphism for all } n. \text{ Then, Theorem 4.2.2 will follow from this by a limit argument. To show that above morphism is an isomorphism, we will utilize Proposition 4.4.4. Note that if any two of the horizontal morphisms in Proposition 4.4.4 is a quasi-isomorphism, so is the third one. Therefore, by an inductive argument, we are reduced to showing that the morphism}
\end{array}
\]

\[
\begin{array}{c}
\text{is an isomorphism for all } n \geq 0. \text{ Note that } \Gamma \text{ acts trivially on } I^n/I^{n+1}. \text{ Therefore, one may view } I^n/I^{n+1} \text{ as a } \Lambda^0\text{-module via the augmentation map } \Lambda \to R. \text{ We now have the following lemma.}
\end{array}
\]

Lemma 4.4.5. Let $T$ be a bounded complex of objects in $\mathcal{C}_{\Lambda,G}$. Then we have the following isomorphisms

\[
\begin{array}{c}
\text{in } \mathbf{D}(\mathcal{C}_{\Lambda,G}). \text{ Therefore, we have an isomorphism}
\end{array}
\]

\[
\text{in } \mathbf{D}^b(\mathcal{C}_{\Lambda,G}).
\]
Proof. Let $P$ be a resolution of $I^n/I^{n+1}$ consisting of projective objects in $\mathcal{C}_{\Lambda^{-\Lambda}}$. Then there is a quasi-isomorphism $P \to [I^{n+1} \to I^n]$ of complexes in $\mathcal{C}_{\Lambda^{-\Lambda}}$ which lifts the identity map on $I^n/I^{n+1}$. By Lemmas 2.4.3 and 4.4.2(a) this induces a quasi-isomorphism

$$P \otimes \Lambda T \to [I^{n+1} \to I^n] \otimes \Lambda T$$

of bounded above complexes in $\mathcal{C}_{\Lambda,G_v}$, proving the first isomorphism. The second isomorphism is a special case of Lemma 3.1.6 with $N = I^n/I^{n+1}$ and $\Gamma'$ trivial. Note that both quasi-isomorphisms of complexes factor through a quasi-isomorphic truncation of $P \otimes \Lambda T$, so they may be seen in the bounded derived category.

**Lemma 4.4.6.** For each $n$, there is a commutative diagram

$$\begin{array}{cccc}
I^n/I^{n+1} \otimes_R \mathbf{R}\Gamma(G_v, T) & \longrightarrow & I^n/I^{n+1} \otimes_R \mathbf{R}\mathrm{Hom}_R\left(\mathbf{R}\Gamma(G_v, T^*(1)), \omega_R\right)[-2] \\
\downarrow & & \downarrow \\
\mathbf{R}\Gamma(G_v, I^n/I^{n+1} \otimes_R T) & \longrightarrow & \mathbf{R}\mathrm{Hom}_R\left(\mathbf{R}\Gamma(G_v, T^*(1)), I^n/I^{n+1} \otimes_R \omega_R\right)[-2] \\
\downarrow & & \downarrow \\
\mathbf{R}\mathrm{Hom}_R\left(\mathbf{R}\Gamma(G_v, \mathcal{F}_T(T^*(1)) \otimes_R J_R(1)), I^n/I^{n+1} \otimes_R \omega_R\right)[-2] & & \mathbf{R}\mathrm{Hom}_{\Lambda} \left(\mathbf{R}\Gamma(G_v, \mathcal{F}_T(T^*(1))), I^n/I^{n+1} \otimes_R \omega_R\right)[-2],
\end{array}$$

where the vertical morphisms are isomorphisms in $\mathbf{D}(\text{Mod}_R)$.

**Proof.** By Lemma 4.4.2(b), we may choose a bounded resolution $Q$ of $I^n/I^{n+1}$ by finitely generated projective $R$-modules. By [Nek] Proposition 3.4.4], we have an isomorphism of complexes

$$\alpha : Q \otimes R C(G_v, T) \simto C(G_v, Q \otimes R T)$$

that fits into the commutative diagram

$$\begin{array}{cccc}
Q \otimes R C(G_v, T) \otimes R C(G_v, T^*(1)) & \longrightarrow & Q \otimes R C(G_v, J_R(1)) \\
\alpha \otimes \text{id} & & \alpha' \\
C(G_v, Q \otimes R T) \otimes R C(G_v, T^*(1)) & \longrightarrow & C(G_v, Q \otimes R J_R(1)),
\end{array}$$

where $\alpha'$ is defined analogously to $\alpha$ and is also an isomorphism. Since $J_R$ is a bounded complex of $R$-injectives, we may find homotopy inverses to the quasi-
isomorphisms $q_R$ and $q_Q$ of Lemma 4.2.1 that fit in a commutative diagram

\[
\begin{array}{ccc}
Q \otimes_R C(G_v, J_R(1)) & \xrightarrow{\alpha'} & Q \otimes_R \tau^{II}_{\geq 2}C(G_v, J_R(1)) \\
\downarrow & & \downarrow \\
C(G_v, Q \otimes_R J_R(1)) & \xrightarrow{\tau^{II}_{\geq 2}} & Q \otimes_R J_R[2].
\end{array}
\]

We obtain the top commutative square in the lemma and the fact that the vertical morphisms therein are isomorphisms, the one on the right by Lemma 2.1.8 and [Nek, Proposition 4.2.3].

Let $P$ be a resolution of $I_n/I_{n+1}$ consisting of finitely generated projective $\Lambda$-modules. We may view $Q$ as a resolution of $\Lambda^\circ$-modules via the augmentation map $\Lambda \rightarrow R$. Then, by Proposition 2.4.6, the map

\[
P \otimes \Lambda F(T) = P \otimes \Lambda^\circ T \rightarrow Q \otimes \Lambda^\circ T \cong Q \otimes_R T
\]

is a quasi-isomorphism of complexes of objects in $C_{R, G}$, and we let $f$ denote its induced map on cochains. Let $L$ be a resolution of $R$ consisting of finitely generated projective $\Lambda$-modules. Then, by an opposite version of Theorem 3.1.8, we have a quasi-isomorphism

\[
g: C(G_v, F_T(T^\ast)(1)) \otimes_A L \rightarrow C(G_v, T^\ast(1))
\]

of complexes of $R$-modules. Noting Lemma 5.3.3 we have a commutative diagram

\[
\begin{array}{ccc}
C(G_v, P \otimes_A F_T(T)) \otimes_R C(G_v, F_T(T^\ast)(1)) \otimes_A L & \xrightarrow{f \otimes \varepsilon} & C(G_v, P \otimes_R J_R(1)) \otimes_A L \\
\downarrow & & \downarrow \\
C(G_v, Q \otimes_R T) \otimes_R C(G_v, T^\ast(1)) & \xrightarrow{\varepsilon} & C(G_v, Q \otimes_R J_R(1)),
\end{array}
\]

where $\varepsilon$ is induced by the augmentation $L \rightarrow R$ and the map $P \rightarrow Q$. Taking adjoints and applying the homotopy inverse to $q_Q$ as above, we obtain the commutative diagram

\[
\begin{array}{ccc}
C(G_v, Q \otimes_R T) & \xrightarrow{\text{Hom}_R} & \text{Hom}_R\left(C(G_v, T^\ast(1)), Q \otimes_R J_R\right)[-2] \\
\downarrow & & \downarrow \\
C(G_v, P \otimes_A F_T(T)) & \xrightarrow{\text{Hom}_R} & \text{Hom}_R\left(C(G_v, F_T(T^\ast)(1)) \otimes_A L, Q \otimes_R J_R\right)[-2] \\
\downarrow & & \downarrow \\
C(G_v, P \otimes_A F_T(T)) & \xrightarrow{\text{Hom}_A} & \text{Hom}_R\left(C(G_v, F_T(T^\ast)(1)), \text{Hom}_R(L, Q \otimes_R J_R)\right)[-2],
\end{array}
\]

which yields upon passage to the derived category the lower part of the diagram in the statement of the lemma, the vertical morphisms therein being isomorphisms by Theorem 3.1.8, Lemma 4.4.5 and Lemma 2.1.6.
**Lemma 4.4.7.** The morphisms

\[ R\Gamma(G_v, \mathcal{F}_{I^n/I^{n+1}}(T)) \to R\text{Hom}_{\Lambda^c}\left(R\Gamma(G_v, \mathcal{F}_T(T^*)^!(1)), I^n/I^{n+1} \otimes_R \omega_R\right)[-2] \]

in \( D(\text{Mod}_\Lambda) \) are isomorphisms for every \( n \geq 0 \).

**Proof.** By Corollary 2.1.3 it suffices to show that the above morphism is an isomorphism in \( D(\text{Mod}_R) \). The morphism

\[ R\Gamma(G_v, T) \to R\text{Hom}_R\left(R\Gamma(G_v, T^*(1)), \omega_R\right)[-2] \]

in \( D(\text{Mod}_R) \) is an isomorphism by [Nek, Proposition 5.2.4(ii)], and so the top morphism of the diagram in Lemma 4.4.6 is an isomorphism. Since all the vertical morphisms in the diagram are isomorphisms, it follows that the bottom morphism is also an isomorphism, as required.

**Proposition 4.4.8.** The morphisms

\[ R\Gamma(G_v, \mathcal{F}_{A/I^n}(T)) \to R\text{Hom}_{\Lambda^c}\left(R\Gamma(G_v, \mathcal{F}_T(T^*)^!(1)), \Lambda/I^n \otimes_R \omega_R\right)[-2] \]

in \( D(\text{Mod}_\Lambda) \) are isomorphisms for every \( n \geq 1 \).

**Proof.** As seen in the above discussion, the preceding lemma allows us to perform an inductive argument using the morphism of exact triangles in Proposition 4.4.4 to obtain the required conclusion.

We finish the proof of Theorem 4.2.2 by passing to the inverse limit.

**Proof of Theorem 4.2.2.** By Remark 4.1.4 there exists a quasi-isomorphism

\[ W \to C(G_v, \mathcal{F}_T(T^*)^!(1)) \]

with \( W \) a bounded above complex of finitely generated projective \( \Lambda^c \)-modules. Since \( J_R \) has cohomology groups which are finitely generated over \( R \), Lemma 2.3.1 implies the existence of a subcomplex \( C \) of \( J_R \) such that \( C \) is a complex of finitely generated \( R \)-modules and the inclusion \( i: C \hookrightarrow J_R \) is a quasi-isomorphism. We fix such a \( C \) and write \( X_n \) for \([I^n \to \Lambda]\). The complex \( \text{Hom}_{\Lambda^c}(W, X_n \otimes_R C) \) represents

\[ R\text{Hom}_{\Lambda^c}\left(R\Gamma(G_v, \mathcal{F}_T(T^*)^!(1)), \Lambda/I^n \otimes_R \omega_R\right) \]

and \( \text{Hom}_{\Lambda^c}(W, \Lambda \otimes_R C) \) represents

\[ R\text{Hom}_{\Lambda^c}\left(R\Gamma(G_v, \mathcal{F}_T(T^*)^!(1)), \Lambda \otimes_R \omega_R\right) \].
since $X_n$ is a complex of flat $R$-modules by Lemma 4.4.2(a). Now, for each $n$, we have a commutative diagram

$$
\begin{array}{cccc}
\text{R}^\Gamma(G_v, \mathcal{F}_T(T)) & \longrightarrow & \text{RHom}_{\Lambda^e} \left( \text{R}^\Gamma(G_v, \mathcal{F}_T(T^*)^i(1)), \Lambda \otimes_R \omega_R \right)[-2] \\
\downarrow & & \downarrow \\
\text{R}^\Gamma(G_v, \mathcal{F}_{\Lambda/I^n}(T)) & \longrightarrow & \text{RHom}_{\Lambda^e} \left( \text{R}^\Gamma(G_v, \mathcal{F}_T(T^*)^i(1)), \Lambda/I^n \otimes_R \omega_R \right)[-2]
\end{array}
$$

which induces a commutative diagram

$$
\begin{array}{cc}
H^i(G_v, \mathcal{F}_T(T)) & \longrightarrow H^{2-i}(\text{Hom}_{\Lambda^e}(W, \Lambda \otimes R C)) \\
\downarrow & \downarrow \\
H^i(G_v, \mathcal{F}_{\Lambda/I^n}(T)) & \longrightarrow H^{2-i}(\text{Hom}_{\Lambda^e}(W, X_n \otimes R C))
\end{array}
$$

of cohomology groups. Since the maps in this diagram are compatible as we vary $n$, we obtain the commutative diagram

$$
\begin{array}{ccc}
\lim H^i(G_v, \mathcal{F}_T(T)) & \longrightarrow & H^{2-i}(\text{Hom}_{\Lambda^e}(W, \Lambda \otimes R C)) \\
\downarrow & & \downarrow \\
\lim H^i(G_v, \mathcal{F}_{\Lambda/I^n}(T)) & \longrightarrow & \lim H^{2-i}(\text{Hom}_{\Lambda^e}(W, X_n \otimes R C)).
\end{array}
$$

It remains to show that the upper horizontal map in the latter diagram is an isomorphism. By Proposition 4.4.3, we know that the lower horizontal map is one. Noting that the maps $X_{n+1} \otimes R C \rightarrow X_n \otimes R C$ are injections of complexes with intersection $\Lambda \otimes R C$ over all $n$, we have an isomorphism

$$
\lim H^i(G_v, \mathcal{F}_{\Lambda/I^n}(T)) \cong H^i(G_v, \mathcal{F}_T(T))
$$

of complexes of finitely generated $\Lambda$-modules. Since inverse limits are exact for finitely generated $\Lambda$-modules (being that they are compact), after taking cohomology groups, we have that the vertical map on the right is an isomorphism. On the other hand, we also have an isomorphism

$$
\lim (X_n \otimes_\Lambda \mathcal{F}_T(T)) \cong \mathcal{F}_T(T)
$$

of complexes of objects in $\mathcal{C}_{\Lambda^e}^{\Lambda^e}$ and hence an isomorphism

$$
\lim C(G_v, X_n \otimes_\Lambda \mathcal{F}_T(T)) \cong C(G_v, \mathcal{F}_T(T)).
$$
where \( \bar{\xi} \) have an isomorphism \( S \) in which are given by the formulas

\[
\otimes_{\Lambda} (\text{ complexes of } \Lambda)
\]

map is an isomorphism, as required. Therefore, the vertical map on the left is also an isomorphism. Hence, the top map is an isomorphism, as required. 

\[\square\]

4.5 Duality over global fields

We end this paper by describing the global analog of Theorem 4.2.2 that is our main result. Let \( T \) be a bounded complex of objects in \( \mathcal{C}^{R,G}_{R,G,F,S} \) and we choose \( T^* \) in \( \mathcal{C}^{R-G}_{R,G,F,S} \) as in Section 3.3. As in [Nek, (5.3.3)], we define two morphisms of complexes of \( \Lambda \otimes_R \Lambda^\omega \)-modules

\[
\cup: C_c(G,F,S, \mathcal{F}_T(T)) \otimes_R C(G,F,S, \mathcal{F}_T(T^*)^!(1)) \to C_c(G,F,S, \Lambda \otimes_R J_R(1))
\]

\[
\cup_c: C(G,F,S, \mathcal{F}_T(T)) \otimes_R C_c(G,F,S, \mathcal{F}_T(T^*)^!(1)) \to C_c(G,F,S, \Lambda \otimes_R J_R(1))
\]

which are given by the formulas

\[
(a, a_S) \cup b = (a \cup b, a_S \cup_S \res_S(b))
\]

\[
a \cup_c (b, b_S) = (a \cup b, (-1)^a \res_S(a) \cup_S b_S),
\]

where \( \bar{\alpha} \) denotes the degree of \( a \), the direct sum of the restrictions to the primes in \( S \) is denoted \( \res_S \), the symbol \( \cup \) is the total cup product

\[
C(G,F,S, \mathcal{F}_T(T)) \otimes_R C(G,F,S, \mathcal{F}_T(T^*)^!(1)) \to C(G,F,S, \Lambda \otimes_R J_R(1))
\]

of Lemma 3.3.3 and \( \cup_S \) is the direct sum of the corresponding local cup products. Much as in Lemma 4.2.1 (but now analogously to [Nek, Lemma 5.7.3]), we have a quasi-isomorphism

\[
\Lambda \otimes_R J_R \to \tau_{R,F}^{-1} C_{(\mathcal{F}_T(T^*)^!(1), \Lambda \otimes_R \omega_R)}[1]
\]

of complexes of \( \Lambda \otimes_R \Lambda^\omega \)-modules, which allows us to use adjoints to define the morphisms in the following theorem.

**Theorem 4.5.1.** Let \( T \) be a bounded complex of objects in \( \mathcal{C}^{R-G}_{R,G,F,S} \). Then we have an isomorphism

\[
\otimes_{\Lambda} (\text{ complexes of } \Lambda)
\]

\[
\begin{array}{cccc}
\mathbf{R} \Gamma_{(\mathcal{F}_T(T^*)^!(1), \Lambda \otimes_R \omega_R)} & \longrightarrow & \mathbf{R} \Hom_{\Lambda^*} \left( \mathbf{R} \Gamma_{(\mathcal{F}_T(T^*)^!(1), \Lambda \otimes_R \omega_R)}[-3] \right) \\

\end{array}
\]

of exact triangles in \( \mathbf{D}_{\Lambda - R}(\text{Mod}_\Lambda) \).
Proof. The morphism of exact triangles can be constructed as in \cite[Theorem 4.2.6]{Lim2}. We remark that it suffices to prove that any two of the three horizontal morphisms is an isomorphism, and we focus on the second and third. By an analogous result to Proposition 4.3.2, we may assume that $R$ is regular and $\mathbb{Z}_p$-flat. That the second of the morphisms is an isomorphism follows as in proof of Theorem 4.2.2. In fact, aside from the obvious changes of notation for cochains and other objects, there are no significant changes to the proof.

As for the third, note that for a nonarchimedean prime $v$ in $\mathcal{S}$, the map\[
\tau_{\geq 2}^{I_1} C(G_v, \Lambda \otimes_R J_R(1)) \longrightarrow \tau_{\geq 2}^{I_1} \left(C(\mathcal{O}(G_{F,S}), \Lambda \otimes_R J_R(1))[1]\right)
\]
is a quasi-isomorphism that induces the identity maps on the cohomology groups of each complex. Under this identification, the map on the $v$-summand in the lower horizontal morphism in the statement is exactly the first isomorphism of Theorem 4.2.2.

It remains to prove that, for a real place $v$, the morphisms\[
R \Gamma(G_v, \mathcal{F}_T(T)) \longrightarrow R \text{Hom}_{\Lambda^\circ} \left(R \Gamma(G_v, \mathcal{F}_T(T^*)^\vee(1)), \Lambda \otimes_R \omega_R\right)[-2]
\]
are isomorphisms in $D_{\Lambda^\circ-\text{R-Mod}}$. There are two cases: either $v$ extends to a complex place or splits completely in $F_\infty$. However, if $v$ becomes complex, then both $\mathcal{C}(G_v, \mathcal{F}_T(T))$ and $\mathcal{C}(G_v, \mathcal{F}_T(T^*)^\vee(1))$ are acyclic, and there is nothing to prove.

If $v$ splits completely in $F_\infty$, then the adjoint map of interest is identified (as in the proof of Proposition 4.1.1) with\[
\Lambda \otimes_R \mathcal{C}(G_v, T) \longrightarrow \text{Hom}_{\Lambda^\circ} \left(\Lambda \otimes_R \mathcal{C}(G_v, T^*(1)), \Lambda \otimes_R J_R\right)[-2],
\]
where\[
\cup : \mathcal{C}(G_v, T) \otimes_R \mathcal{C}(G_v, T^*(1)) \longrightarrow J_R[-2]
\]
is given by cup product followed by the maps\[
\mathcal{C}(G_v, J_R(1)) \longrightarrow \tau_{\geq 2}^{I_1} \mathcal{C}(G_v, J_R(1)) \longrightarrow \tau_{\geq 2}^{I_1} \left(C(\mathcal{O}(G_{F,S}), J_R(1))[1]\right) \longrightarrow J_R[-2],
\]
the latter being a homotopy inverse to the inclusion of complexes.

Suppose now that we have a quasi-isomorphism $D \rightarrow \mathcal{C}(G_v, T^*(1))$ with $D$ a $g$-projective complex of finitely generated $R$-modules. In the commutative
of canonical maps, the lower right vertical map is an isomorphism by Lemma 2.1.7 (the terms of $D$ being finitely generated over $R$), and the lower horizontal morphism is a quasi-isomorphism by the $R$-injectivity of the terms of $J_R$ and the $R$-flatness of $\Lambda$. It follows that the derived adjoint morphism is represented by a morphism

\[ \Lambda \otimes_R \tilde{C}(G_v, T^*(1)) \longrightarrow \Lambda \otimes_R \text{Hom}_R(\tilde{C}(G_v, T^*(1)), J_R)[{-2}] \]

that by construction takes $\lambda \otimes f$ to $\lambda \otimes (g \mapsto f \cup g)$, which is the tensor product of the identity map with the derived adjoint that is already known to be a quasi-isomorphism by [Nek, (5.7.5)].

We are left to construct $D$, the existence of which is not so obvious as $\tilde{C}(G_v, T^*(1))$ need not have bounded cohomology. However, as is seen in [Spa, Lemma 3.3] (see also [Kel, Appendix]), such a complex may be constructed as a direct limit $\lim \rightarrow \lim D_n$ using maps $\alpha_n : D_n \to D_{n+1}$ that are split injective in each degree, and where

\[ D_0 \longrightarrow \tau_{\leq 0} \tilde{C}(G_v, T^*(1)) \]

is a quasi-isomorphism from a bounded above complex of finitely generated $R$-projectives and $E_n = D_n/\alpha_{n-1}(D_{n-1})$ for $n \geq 1$ is chosen to be quasi-isomorphic to

\[ \text{Cone} \left( \tau_{\leq n-1} \tilde{C}(G_v, T^*(1)) \longrightarrow \tau_{\leq n} \tilde{C}(G_v, T^*(1)) \right), \]

which has bounded, $R$-finitely generated cohomology. Since $R$ has finite global dimension, we may choose the $E_n$ as bounded complexes of finitely generated projective $R$-modules such that, for each $k$, only finitely many $E^n_k$ are nonzero, which is what was needed.

We end with a straightforward remark.

**Remark 4.5.2.** There is also an analogous diagram and isomorphisms for the other adjoint, with morphisms as in the second map in Theorem 4.2.2, and this follows, for instance, by a nearly identical argument.

Abstract. Let $X$ be a minuscule homogeneous space, an odd-dimensional quadric, or an adjoint homogeneous space of type different from $A$ and $G_2$. Let $C$ be an elliptic curve. In this paper, we prove that for $d$ large enough, the scheme of degree $d$ morphisms from $C$ to $X$ is irreducible, giving an explicit lower bound for $d$ which is optimal in many cases.

2010 Mathematics Subject Classification: 14M15, 14N35

Keywords and Phrases: Elliptic curves, minuscule homogeneous spaces, adjoint homogeneous spaces.

Introduction

In this paper we study the scheme $\text{Hom}_d(C, X)$ of degree $d$ morphisms from an elliptic curve $C$ to a rational homogeneous space $X$. Specifically we will assume that $X$ is either a minuscule homogeneous space or an adjoint homogeneous space. Minuscule homogeneous spaces\(^1\) are a natural generalisation of Grassmann varieties (see Table 1). Adjoint homogeneous spaces are also called quasi-minuscule and are obtained as the unique closed orbits in $\mathbb{P}g$ under the adjoint action. These varieties are also called minimal nilpotent orbits (see Table 2).

We prove that the scheme $\text{Hom}_d(C, X)$ is irreducible as soon as $d$ is large enough and we give an explicit bound $d(X)$ for $d$ (see Tables 1 and 2).

---

\(^1\)A homogeneous space $X$ is minuscule if the minimal representation $V$ defining an embedding $X \subset \mathbb{P}(V)$, also called the Plücker embedding, is a minuscule representation i.e. a representation of highest weight $\varpi$ with $|\langle \alpha^\vee, \varpi \rangle| \leq 1$ for all roots $\alpha$. The space $X$ is cominuscule if the above highest weight $\varpi$ is fundamental and its associated fundamental coweight is minuscule.
**Theorem 0.1** Let $C$ be a smooth elliptic curve and let $X$ be a minuscule or an adjoint homogeneous space. If $X$ is of adjoint type, assume furthermore that the group $G$ is not of type $A$ or $G_2$. For $d \geq d(X)$, the scheme of morphisms $\text{Hom}_d(C,X)$ is irreducible of dimension $c_1(X)d$.

In many cases, we also prove that the bound $d(X)$ is optimal in the following sense: for $d < d(X)$, the scheme $\text{Hom}_d(C,X)$ has dimension strictly bigger than the expected dimension $c_1(X)d$. Note that it may happen that for $d < d(X)$ the scheme $\text{Hom}_d(C,X)$ is irreducible. This is the case for all $d$ when $X$ is isomorphic to the maximal isotropic Grassmann variety $G_Q(n,2n)$ (see Table 1 and Corollary 3.9).

**Remark 0.2** (ı) Note that B. Kim and R. Pandharipande proved the connectedness of the moduli space of stable maps $\overline{M}_{d,g}(X)$ to any homogeneous space and for any genus. However, this space is almost never irreducible since there will be irreducible components of unexpected dimension (see Proposition 4.2).

(ii) Note also that for $d = 2$, the scheme of morphisms $\text{Hom}_d(C,X)$ to any homogeneous space with Picard rank 1 is irreducible of dimension $c_1(X) + \dim X + 1$. Indeed, any degree 2 morphism factors through a line.

Minuscule and adjoint homogeneous spaces are of the form $G/P$ for a semisimple algebraic group $G$. Except for the adjoint homogeneous space of type $A$, the parabolic subgroup $P$ is a maximal parabolic subgroup. This is the reason why we will assume that if $X$ is of adjoint type the group $G$ is not of type $A$. Recall that the Dynkin diagram of the group $G$ has vertices indexed by simple roots. In the following tables, we give the list of all minuscule homogeneous spaces. Note that we also include odd dimensional quadrics which are not minuscule but cominuscule. The above statement is still true for odd dimensional quadrics.

In Table 1, we give the list of all adjoint homogeneous spaces for a group of type different from $A$. In this table we also include the adjoint variety of type $G_2$ even though we have no result for this variety.

In these tables, we followed the notation of [Bou54, Tables] and we depicted the set $\Delta(P)$ of simple roots not in $P$ with plain vertices. The minuscule and adjoint varieties $X = G/P$ are described in the second column. By convention we denote by $G(k,n)$ (resp. $G_Q(k,n)$) the Grassmann variety of $k$-dimensional subspaces in $\mathbb{C}^n$ (resp. isotropic $k$-dimensional subspaces in $\mathbb{C}^n$ for a non-degenerate quadratic form $Q$ in $\mathbb{C}^n$). For $G_Q(n,2n)$ we only consider one of the two connected components of the above Grassmann variety. We denoted by $Q_m$ any smooth $m$-dimensional quadric. The varieties $\mathbb{O}P^2 = E_6/P_1$ and $E_7/P_7$ are the Cayley plane and the Freudenthal variety. Recall that the index of $X = G/P$ is the integer $c_1(X)$ such that the anticanonical divisor $-K_X$ equals $c_1(X)H$ where $H$ is an ample generator of the Picard group. The last column gives the bound $d(X)$ of our main theorem.

**Remark 0.3** Note that the above statement was already known for Grassmann varieties by results of A. Bruguieres [Bru87] and for quadrics by results of E.

Ballico [Bal89]. Note also that for orthogonal Grassmann varieties, the above result was obtained by another technique by the second author in the paper [Per12]. This case was the very first motivation for our study. It answered a question of D. Markushevitch and has been used in [IM07].

Remark 0.4 Note that the choice of minuscule and adjoint varieties for studying elliptic curves is not a random one. Indeed, already in the study of rational curves and their associated enumerative properties encoded in quantum cohomology, these variety have very special properties, see for example [Buc03, BKT03, BM11, BCMP10, CMP08, CMP07, CMP10] for minuscule homogeneous spaces and [CP11b] for adjoint varieties.

Let us briefly describe the content of the paper. The strategy of the proof relies on a description given in [Per02] of a big open cell $U$ in any homogeneous space $X$ as a tower of affine bundles $\phi : U \to Y$ (see Definition 1.2) where $Y$ is again homogeneous under a smaller group. In section 1 we explain how to restrict the study of the irreducibility of $\text{Hom}_d(C, X)$ to the one of $\text{Hom}_d(C, U)$ and we explain, under some conditions on the fibration $\phi : U \to Y$, how to deduce the irreducibility of $\text{Hom}_d(C, U)$ from the irreducibility of $\text{Hom}_d(C, Y)$. In section 1.3, we recall the construction of $U$ and of the the fibration $\phi : U \to Y$ and describe the tower of affine fibrations. In section 2, we prove some results on the cohomology of the restriction to elliptic curves of equivariant locally free sheaves on projective spaces quadrics. In section 3, we gather all these results to prove Theorem 0.1. In section 4, we include some remarks on the moduli space of stable maps to minuscule or adjoint homogeneous spaces with source an elliptic curve. Finally, in an appendix we deal with the quadric of dimension 3, which we cannot approach by the same method as all other homogeneous spaces.

Acknowledgments. The second author would like to thank Christian Peskine for enlightening discussions on the paper [GLP83] and Piotr Achinger for useful comments on spinor bundles. Part of this work was done while both authors were supported by Hausdorff Center for Mathematics in Bonn. We thank the HCM for perfect working conditions.

A THE QUADRIC OF DIMENSION 3 700

1 REDUCTION OF THE THEOREM 700

1.1 Restriction to an open subset

Let $C$ be a smooth curve, let $X$ be a homogeneous space with Picard number 1 and let $\alpha \in A_1(X)$. The strategy of the proof will be similar to the one in [Per02]. We prove that there exists an open subset $U$ of $X$ whose complement is of codimension at least 2 and such that $U$ can be realised as a tower of affine bundles $\phi : U \to Y$ (see Definition 1.2 below) over a homogeneous space $Y$ of smaller dimension. The next result from [Per02, Proposition 2] proves that the irreducibility of $\text{Hom}_i(\alpha, U)$ is equivalent to the irreducibility of $\text{Hom}_i(\alpha, C)$ (where $i : U \to X$ is the inclusion morphism). This result is an easy application of Kleiman-Bertini Theorem [Kle74].

PROPOSITION 1.1 Let $C$ be a smooth curve and let $X$ be a homogeneous space under a group $G$. Assume that $U$ be an open subset of $X$ such that $\text{Codim}_X(X \setminus U) \geq 2$ and let $i : U \to X$ be the inclusion morphism. For $\alpha \in A_1(X)$, if $\text{Hom}_{i\ast \alpha}(C, U)$ is irreducible, then so is $\text{Hom}_{i\ast \alpha}(C, X)$.

We then need to study the open subset $U$. It will be the open orbit of the action of some parabolic subgroup of $G$ on $X$. The second author proved in [Per02] that $U$ can be realised as a tower $\phi : U \to Y$ of affine bundles (see Definition 1.2) over a homogeneous space $Y$ of smaller dimension. However, if this was enough to study rational curves, we need to be more precise if we want to study higher genus curves. If $\phi : U \to Y$ is an affine bundle associated to a vector bundle $E$, we explain in the next subsection how a good understanding of the restriction of $E$ to higher genus curves in $Y$ enables us to proceed by induction on the dimension.
1.2 Passing through towers of affine bundles

Let us fix some notation. In this section \( X \) is a homogeneous space of Picard number 1, we denote by \( U \) an open subset whose complement \( Z \) is of codimension 2 and we assume that \( U \) can be realised as a tower of affine bundles \( \phi : U \to Y \) over a homogeneous space \( Y \) of smaller dimension in the following sense.

**Definition 1.2** Let \( n \) be a non negative integer and for all \( i \in [1, n-1] \), let \( \phi_i : X_i \to X_{i+1} \) be an affine bundle. Let \( U = X_1 \) and \( Y = X_n \). The composition morphism \( \phi : U \to Y \) is called a tower of affine bundles over \( Y \).

Note that because of the inequality \( \text{Codim}_X Z \geq 2 \), we have \( \text{Pic}(U) = \text{Pic}(X) \). Furthermore since \( \phi : U \to Y \) is a tower of affine bundles, then we also have \( \text{Pic}(U) = \text{Pic}(Y) \). For \( f : C \to U \) a morphism, we may define a linear form \([f]\) on \( \text{Pic}(X) \) by \( \mathcal{L} \mapsto \deg(f^* \mathcal{L}) \). We shall say that for \( \alpha \in \text{Pic}(X)^\vee \) a curve \( f : C \to U \) is of class \( \alpha \) if \([f] = \alpha \). We shall write \( \langle \alpha, \mathcal{L} \rangle \) for the evaluation of \( \alpha \) at \( \mathcal{L} \in \text{Pic}(X) \). For such a class \( \alpha \) in \( \text{Pic}(X)^\vee \), we denote by \( \text{Hom}_\alpha(C, U) \) resp. \( \text{Hom}_\alpha(C, Y) \) the scheme of morphisms from \( f : C \to X \) resp. \( f : C \to U, f : C \to Y \) such that \([f] = \alpha \). Note that for \( X \) (or for \( Y \)) we have identifications \( A_1(X) \simeq \text{Pic}(X)^\vee \) and \( A_1(Y) \simeq \text{Pic}(Y)^\vee \) and that these schemes of morphisms are the classical schemes of morphisms as defined in [Gro61].

We now prove a general result on the scheme of morphisms to an affine bundle. For this we introduce the following notation. Let \( \phi : U \to Y \) be an affine bundle with direction vector bundle \( E \) on \( Y \) and let \( \alpha \in \text{Pic}(U)^\vee \). We denote by \( H_b \) the locally closed subset of \( \text{Hom}_{\phi, \alpha}(C, Y) \) defined by

\[
H_b = \{ f \in \text{Hom}_{\phi, \alpha}(C, Y) \mid \dim H^1(C, f^* E) = b \}.
\]

**Proposition 1.3** Let \( \phi : U \to Y \) be an affine bundle over a variety \( Y \) with direction vector bundle \( E \). Let \( \alpha \in \text{Pic}(U)^\vee \) and let \( C \) be a smooth curve such that the scheme \( \text{Hom}_{\phi, \alpha}(C, Y) \) is irreducible of dimension \( \langle \phi, \alpha, c_1(T_Y) \rangle \).

(i) Assume that there exists \( f \in \text{Hom}_{\phi, \alpha}(C, Y) \) satisfying the vanishing \( H^1(C, f^* E) = 0 \). If for all integer \( b > 0 \) we have the inequality \( \text{Codim} H_b > b \), then \( \text{Hom}_{\alpha}(C, U) \) is irreducible of dimension \( \langle \alpha, c_1(T_U) \rangle \).

(ii) Assume that \( \phi \) is a vector bundle and let \( a \) be the smallest integer such that there exists an element \( f \in \text{Hom}_{\phi, \alpha}(C, Y) \) with \( \dim H^1(C, f^* E) = a \). If there exists an integer \( b > a \) satisfying the inequality \( \text{Codim} H_b \leq b - a \), then the scheme \( \text{Hom}_{\alpha}(C, U) \) is reducible.

**Proof.** (i) Let us consider the natural morphism \( \text{Hom}_{\alpha}(C, U) \to \text{Hom}_{\phi, \alpha}(C, Y) \). As explained in [Per02] for rational curves, the fiber of this map over an element \( f \in \text{Hom}_{\phi, \alpha}(C, Y) \) is given by the sections \( s \in H^0(C, f^* E) \). In particular, such a section exists if and only if the affine bundle \( C \times Y U \to C \) obtained by pull-back to \( C \) is a vector bundle. For a
general element \( f \in \text{Hom}_{\Phi,\alpha}(C,Y) \) this is the case thanks to the vanishing \( H^1(C,f^*E) = 0 \).

For \( b > 0 \) the fibers over the locally closed subset \( H_b \) are either empty (if the pull-back is not a vector bundle) or of dimension \( \dim H^b(C,f^*E) = \chi(C,f^*E) + \dim H^1(C,f^*E) + \langle \phi_\alpha, c_1(E) \rangle + b \). The dimension of the inverse image of \( H_b \) in \( \text{Hom}_{\alpha}(C,U) \) is therefore strictly less than \( \langle \phi_\alpha, c_1(T_Y) + c_1(E) \rangle = \langle \alpha, c_1(T_Y) \rangle \), which is the expected dimension of \( \text{Hom}_{\alpha}(C,U) \). As any irreducible component is at least of this expected dimension (cf. [Mor79]), these locally closed subsets do not form irreducible components. Therefore the inverse image of the open subset \( H_0 \) is dense in \( \text{Hom}_{\alpha}(C,U) \). As explained in [Per02] for rational curves, this inverse image is an affine bundle over the base and is thus irreducible of dimension \( \langle \phi_\alpha, c_1(T_Y) + c_1(E) \rangle = \langle \alpha, c_1(T_Y) \rangle \).

(1) In this case, the inverse image of the locally closed subset \( H_b \) is of dimension \( \langle \alpha, c_1(T_Y) \rangle + a \) while the inverse image of the locally closed subset \( H_b \) is of dimension at least \( \langle \alpha, c_1(T_Y) \rangle + a \). This second locally closed subset is therefore not contained in the closure of the first one, thus they have to be contained in two different irreducible components.

\[ \square \]

1.3 Decomposition of \( X \)

The aim of this subsection is to describe a big open cell \( U \) in the homogeneous space \( X \) and to realise it as a fibration \( \phi : U \to Y \) over a space \( Y \) homogeneous under a group of smaller rank. This fibration can be decomposed in general as a tower of affine bundles (see [Per02, Proposition 5]). Let us recall this result. Let \( T \) be a maximal torus in \( G \) and let \( B \) be a Borel subgroup of \( G \) containing \( T \). Denote by \( w_0 \) the longest element of the Weyl group \( W \) of \((G,T)\). For any subgroup \( H \) of \( G \), we set \( H^{w_0} := w_0 H w_0^{-1} \) and for any parabolic subgroup \( P \) of \( G \) containing \( B \), we denote by \( L_P \) the Levi subgroup of \( P \) containing \( T \) and by \( U_P \) the unipotent radical of \( P \). We also denote by \( \{1\} = U_P^0 \subset U_P^1 \subset \cdots \subset U_P^r \) the upper central series of the group \( U_P \). For any parabolic subgroup \( P \) containing \( B \), we denote by \( \Sigma(P) \) the set of simple roots which are not roots of \( P \). Finally, for a simple root \( \alpha \), we denote by \( \iota(\alpha) \) its image via the Weyl involution \( i.e. \, \iota(\alpha) = -w_0(\alpha) \).

**Lemma 1.4 (Proposition 5 and 6, [Per02])** Let \( P \) and \( Q \) be two parabolic subgroups of \( G \) containing \( B \) and assume that \( \iota(\Sigma(P)) \cap \Sigma(Q) = \emptyset \). Set \( U := Q^{w_0} P / P \). Then \( U \) is an open subset of \( G / P \) with complement in codimension at least 2 and admits an \( L_{Q^{w_0}} \) equivariant fibration \( \phi : U \to Y \) over the flag variety \( Y = L_{Q^{w_0}} / (L_{Q^{w_0}} \cap P) \). Moreover this fibration decomposes in a tower of affine bundles

\[
U = X_1 \xrightarrow{\phi_1} X_2 \xrightarrow{\phi_2} \cdots \xrightarrow{\phi_{r-2}} X_{r-1} \xrightarrow{\phi_{r-1}} X_r = Y
\]

\( ^2\)Recall that the upper central series \( (Z^k(G))_{k \geq 0} \) of a group \( G \) is defined by induction by \( Z^0(G) = \{1\}, \, Z^1(G) = Z(G) \) the center of \( G \) and \( Z^{k+1}(G) \) is the (normal) subgroup of \( G \) containing \( Z^k(G) \) such that \( Z^{k+1}(G) / Z^k(G) = Z(G/Z^k(G)) \).
such that the vector bundle associated to the affine bundle \( \phi_i : X_i \rightarrow X_{i+1} \) is obtained by pull-back from \( Y \) of the \( L_{Q^0} \)-equivariant vector bundles associated to the \( L_{Q^0} \cap P \) representations \( U_{Q^0} / U_{Q^0} \cdot (U_{Q^0} \cap P) \).

**Remark 1.5** Note that it is easy to determine the weights of \( T \) on the representation \( U_{Q^0} / U_{Q^0} \cdot (U_{Q^0} \cap P) \) defining the vector bundle. For example for maximal parabolic subgroups \( P \) and \( Q \) with \( \Sigma(P) = \{ \alpha_P \} \) and \( \Sigma(Q) = \{ \alpha_Q \} \), the weights of the above representation are the negative roots \( \alpha \) such that the coefficient of \( \alpha \) on \( \alpha_P \) is negative and the coefficient of \( \alpha \) on \( \alpha_Q \) is exactly \(-i\). Keeping the previous notation we deduce the existence of the following fibrations. In the next result we will use the description of simple roots given in [Bou54, Tables]

**Corollary 1.6** We have the following fibrations.

1. If \( G \) is of type \( A_n \), if \( \Sigma(P) = \{ \alpha_i \} \) with \( 2 \leq i \leq n \) and if \( \Sigma(Q) = \{ \iota(\alpha_{i-1}) \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{n-i+1} \) and \( \phi : U \rightarrow Y \) is the vector \((T_{P_{n-i}}(-1))(\mathbb{P}^{n-i+1}) \oplus (\Omega_{P_{n-i}}^1(n-i+1))^{\oplus i-1} \).

2. If \( G \) is of type \( B_n \), if \( \Sigma(P) = \{ \alpha_1 \} \) and if \( \Sigma(Q) = \{ \alpha_n \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{n-1} \) and \( \phi : U \rightarrow Y \) is a tower of affine fibrations whose direction vector bundles are pull-backs of \( \mathcal{Q}_{\mathbb{P}^{n-1}}(1) \) and \( \Omega_{\mathbb{P}^{n-1}}^1(2) \).

3. If \( G \) is of type \( D_n \), if \( \Sigma(P) = \{ \alpha_2 \} \) and if \( \Sigma(Q) = \{ \alpha_1 \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{2n-3} \) and \( \phi : U \rightarrow Y \) is the vector bundle \((\mathcal{Q}_{\mathbb{P}^{2n-3}}(1))^\perp \) i.e. the restriction of the tautological quotient bundle on \( \mathbb{P}^{2n-3} \) to \( \mathbb{Q}_{2n-4} \).

4. If \( G \) is of type \( D_n \), if \( \Sigma(P) = \{ \alpha_1 \} \) and if \( \Sigma(Q) = \{ \alpha_n \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{n-2} \) and \( \phi : U \rightarrow Y \) is the vector bundle \( \Omega_{\mathbb{P}^{n-2}}^1(2) \).

5. If \( G \) is of type \( D_n \), if \( \Sigma(P) = \{ \alpha_2 \} \) and if \( \Sigma(Q) = \{ \alpha_1 \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{2n-4} \) and \( \phi : U \rightarrow Y \) is the vector bundle \((\mathcal{Q}_{\mathbb{P}^{2n-4}}(1))^\perp \) i.e. the restriction of the tautological quotient bundle on \( \mathbb{P}^{2n-3} \) to \( \mathbb{Q}_{2n-4} \).

6. If \( G \) is of type \( D_n \), if \( \Sigma(P) = \{ \alpha_n \} \) and if \( \Sigma(Q) = \{ \iota(\alpha_{n-1}) \} \), then \( Y \) is isomorphic to \( \mathbb{P}^{n-1} \) and \( \phi : U \rightarrow Y \) is the vector bundle \( \Omega_{\mathbb{P}^{n-2}}^1(n-2) \).

7. If \( G \) is of type \( E_6 \), if \( \Sigma(P) = \{ \alpha_1 \} \) and if \( \Sigma(Q) = \{ \iota(\alpha_6) \} = \{ \alpha_1 \} \), then \( Y \) is isomorphic to \( \mathbb{Q}_8 \) and \( \phi : U \rightarrow Y \) is one of the two spinor bundles on \( \mathbb{Q}_8 \).

8. If \( G \) is of type \( E_6 \), if \( \Sigma(P) = \{ \alpha_2 \} \) and if \( \Sigma(Q) = \{ \alpha_1, \alpha_6 \} \), then \( Y \) is isomorphic to \( \mathbb{Q}_6 \) and \( \phi : U \rightarrow Y \) is a tower of affine bundles whose direction vector bundles are pull-backs of \( E = (\mathcal{Q}_{\mathbb{Q}_6}(1))^\perp \) and \( E' = S \oplus S' \) where \( E \) is the restriction of the tautological quotient bundle of \( \mathbb{P}^7 \) to \( \mathbb{Q}_6 \) and \( S \) and \( S' \) are the two spinor bundles on \( \mathbb{Q}_6 \).
Elliptic Curves on Some Homogeneous Spaces

9. If $G$ is of type $E_7$, if $\Sigma(P) = \{\alpha_7\}$ and if $\Sigma(Q) = \{\alpha_2\}$, then $Y$ is isomorphic to $\mathbb{P}^6$ and $\phi : U \to Y$ is a tower of affine bundles whose direction vector bundles are pull-backs of $E = \Omega^2_{\mathbb{P}^6}(6)$ and $E' = \Omega^2_{\mathbb{P}^6}(3)$.

10. If $G$ is of type $E_7$, if $\Sigma(P) = \{\alpha_2\}$ and if $\Sigma(Q) = \{\alpha_6\}$, then $Y$ is isomorphic to $\mathbb{P}^6$ and $\phi : U \to Y$ is a tower of affine bundles whose direction vector bundles are pull-backs of $E = (\mathcal{O}_{\mathbb{P}^6}(1))^\perp$ and $E' = S^2$ where $E$ is the restriction of the tautological quotient bundle of $\mathbb{P}^6$ to $\mathbb{P}^6$ and $S$ is one of the two spinor bundles on $\mathbb{P}^6$.

11. If $G$ is of type $E_8$, if $\Sigma(P) = \{\alpha_8\}$ and if $\Sigma(Q) = \{\alpha_1\}$, then $Y$ is isomorphic to $\mathbb{P}^{12}$ and $\phi : U \to Y$ is a tower of affine bundles whose direction vector bundles are pull-backs of $E = (\mathcal{O}_{\mathbb{P}^{12}}(1))^\perp$ and $E' = S$ where $E$ is the restriction of the tautological quotient bundle of $\mathbb{P}^{13}$ to $\mathbb{P}^{12}$ and $S$ is one of the two spinor bundles on $\mathbb{P}^{12}$.

12. If $G$ is of type $F_4$, if $\Sigma(P) = \{\alpha_1\}$ and if $\Sigma(Q) = \{\alpha_4\}$, then $Y$ is isomorphic to $\mathbb{P}^5$ and $\phi : U \to Y$ is a tower of affine bundles whose direction vector bundles are pull-backs of $E = (\mathcal{O}_{\mathbb{P}^5}(1))^\perp$ and $E' = S$ where $E$ is the restriction of the tautological quotient bundle of $\mathbb{P}^{10}$ to $\mathbb{P}^5$ and $S$ is the spinor bundle on $\mathbb{P}^5$.

Proof. According to the previous Lemma, we only need to identify in each case the direction vector bundles of the affine bundles and to notice (see [Per02] proof of Proposition 5) that the first affine bundle over $Y$ is always a vector bundle.

To identify the vector bundles, we only have to identify the corresponding representations. Indeed, recall from [Per02, Proposition 5] that the direction vector bundles are equivariant and correspond to the $L_{\mathbb{P}^n} \cap P$-representations $U_{\mathbb{P}^n}^i \cap U_{\mathbb{P}^n}^{i-1}$, $(U_{\mathbb{P}^n}^i \cap P)$. We therefore only have to compute their highest weight which is an easy check using [Bou54, Tables]. Note that the representation corresponding to the sheaf $(\mathcal{O}_{\mathbb{P}^5}(1))^\perp$ on an $n$-dimensional quadric is not irreducible as a representation of the semisimple part of $L_{\mathbb{P}^n} \cap P$ but is an irreducible non simple representation of $L_{\mathbb{P}^n} \cap P$. Note also that the above description of vector bundles for the adjoint varieties were given in [CP11]. $\Box$

2 Restriction of some homogeneous vector bundles to curves

In this section we gather some known results and some new ones on the geometry of curves in the projective space and in smooth quadrics. As explained in the previous sections, all the affine bundles $\phi : U \to Y$ we have to consider are homogeneous vector bundles over these varieties. Therefore the main aim of the section is to control the cohomology of the pull-back to curves of some equivariant vector bundles. Even if we only need these results for elliptic curves, we state them for any curve of genus $g$.
2.1 Projective spaces

In this subsection we recall some results on secants to a curve. The following result can be found in [Har77, Proposition IV.3.8 and Theorem IV.3.9].

**Proposition 2.1** Let $C$ be a reduced and irreducible curve in $\mathbb{P}^r$ such that any secant line to $C$ is a multisecant, then $C$ is a line.

We will use this statement via the following corollary.

**Corollary 2.2** Let $C$ be a reduced and irreducible curve in $\mathbb{P}^r$ which is not a line, then there exists a point $x$ in $C$ such that the projection from $x$ is birational from $C$ onto its image.

Let $C$ be a smooth curve of genus $g$ and let $f : C \to \mathbb{P}^r$ be a morphism such that $f^*\mathcal{O}_{\mathbb{P}^r}(1)$ is of degree $d$. We want to prove that the pull back of the homogeneous bundles $\Omega^k_{\mathbb{P}^r}(k)$ through $f$ admits nice filtrations. The following lemma can be found in [GLP83, Remark (2) page 498].

**Lemma 2.3** Assume that $f$ is locally injective and that $f(C)$ is non degenerate i.e. not contained in an hyperplane. Then, for almost all choices of $r-1$ points $(x_i)_{i \in [1,r-1]}$ in $C$, there exists a filtration

$$0 = F^{r+1} \subset F^r \subset \cdots \subset F^1 = f^*\Omega^1_{\mathbb{P}^r}(1)$$

such that $F^i/F^{i+1} = \mathcal{O}_C(-x_i)$ for $i \in [1,r-1]$ and $F^r/F^{r+1} = f^*\mathcal{O}_{\mathbb{P}^r}(-1) \otimes \mathcal{O}_C(\sum_{i} x_i)$.

**Proof.** Let us set $M = f^*\Omega^1_{\mathbb{P}^r}(1)$ and $L = f^*\mathcal{O}_{\mathbb{P}^r}(1)$. Let us also denote by $V^\vee$ the vector space $H^0(\mathbb{P}^r, \mathcal{O}_{\mathbb{P}^r}(1))$. Because $f(C)$ is non degenerate, we may consider $V^\vee$ as a subspace of $H^0(C,L)$. We have an exact sequence $0 \to M \to V^\vee \otimes \mathcal{O}_C \to L \to 0$.

We proceed by induction on $r$. Let us choose a point $x_1$ on $C$. Let us denote by $W^\vee$ the intersection $V^\vee \cap H^0(C, L(-x_1))$ in the vector space $H^0(C,L)$. If $f(x_1)$ is smooth, the map $W^\vee \otimes \mathcal{O}_C \to L(-x_1)$ is surjective and we have the commutative diagram:

$$
\begin{array}{cccccc}
W^\vee \otimes \mathcal{O}_C & \to & L(-x_1) \\
0 & \to & M & \to & V^\vee \otimes \mathcal{O}_C & \to & L & \to & 0 \\
0 & \to & \mathcal{O}_C(-x_1) & \to & \mathcal{O}_C & \to & \mathcal{O}_{x_1} & \to & 0.
\end{array}
$$

The snake lemma implies that the left most vertical map is surjective and we get the term $F^2$ of the filtration by taking the kernel of this map which is also
the kernel of the map $W^\vee \otimes \mathcal{O}_C \to L(-x_1)$. Replacing $V$ by $W$ and $L$ by $L(-x_1)$, we get a morphism $f_2$ from $C$ to $\mathbb{P}^{r-1}$ and $F^2 = f_2^* \mathcal{O}_{\mathbb{P}^{r-1}}$. The morphism $f_2$ is the composition of $f$ with the projection with center $x_1$ and because, in characteristic zero, general secants are not multisecant (see Corollary 2.2), $f_2$ is also generically injective for $x_1$ general. We may apply then the induction hypothesis. For $r = 1$, the result is true. □

**Remark 2.4** Note that in the above filtration, all the vector bundles $E^i$ are constructed as tautological subbundles, therefore their dual are globally generated.

**Corollary 2.5** Assume that $f(C)$ is non degenerate, then for almost all choices of $r - 1$ points $(x_i)_{i \in [1, r-1]}$ in $C$, there exists a filtration

$$0 = G^{s+1} \subset G^s \subset \cdots \subset G^1 = f^* \Omega_{\mathbb{P}^r}^1(k)$$

such that $G^i/G^{i+1} = \mathcal{O}_C(-(x_{i_1} + \cdots + x_{i_k}))$ with $\{i_1, \cdots, i_k\} \subset [1, r-1]$ or $G^i/G^{i+1} = f^* \mathcal{O}_{\mathbb{P}^r}(-1) \otimes \mathcal{O}_C(x_{i_1} + \cdots + x_{i_{r-k}})$ with $\{i_1, \cdots, i_{r-k}\} \subset [1, r-1]$.

**Proof.** We simply take the $k$-th exterior product of the previous filtration. □

**Corollary 2.6** Assume that $f(C)$ is non degenerate. Let $g$ be the genus of $C$ and $d$ the degree of $f^* \mathcal{O}_{\mathbb{P}^r}(-1)$. If $g \leq r - k$, then we have the vanishing $H^1(C, f^* \Omega_{\mathbb{P}^r}^1(k+1)) = 0$.

**Proof.** Indeed, for $g \leq r - k$ and for general points $(x_i)_{i \in [1, r-1]}$ on $C$, we have the vanishing $H^1(C, \mathcal{O}_C(x_{i_1} + \cdots + x_{i_{r-k}})) = 0$. Note that because $f(C)$ is non degenerate, we must have the inequality $g \leq d - r \leq d - k$ and this condition implies the following vanishing $H^1(C, f^* \mathcal{O}_{\mathbb{P}^r}(-1) \otimes \mathcal{O}_C(-(x_{i_1} + \cdots + x_{i_k}))) = 0$. □

Let us assume that $C$ is elliptic. Then even if $f(C)$ is degenerate we may obtain results. Indeed, if $f(C)$ is degenerate, there is a minimal linear space $H$ in $\mathbb{P}^r$ of codimension say $a$ containing $f(C)$ and such that $f(C)$ is non degenerate in $H$. Furthermore we have the exact sequence $0 \to \mathcal{O}_C \to f^* \Omega_{\mathbb{P}^r}^1 \to f^* \Omega_{\mathbb{P}^r}^1(k+1) \to 0$ from which we deduce a filtration of $f^* \Omega_{\mathbb{P}^r}^1(1)$. In particular we get the following result.

**Proposition 2.7** Assume that $C$ is elliptic. If $f(C)$ is non degenerate in a linear subspace of codimension $a$, then we have the equality $\dim H^1(C, f^* \Omega_{\mathbb{P}^r}^1(k+1)) = \binom{a}{r-a}$. (with $\binom{a}{r} = 0$ if $a < r - k$).

In particular, if we have the inequality $\dim H^1(C, f^* \Omega_{\mathbb{P}^r}^1(k+1)) > 0$, then there exists an integer $a \geq r - k$ such that $\dim H^1(C, f^* \Omega_{\mathbb{P}^r}^1(k+1)) = \binom{a}{r-a}$ and $f(C)$ in non degenerate in a linear subspace of codimension $a$. 

Documenta Mathematica 18 (2013) 679–706
**Proof.** Taking the k-th exterior power of the exact sequence 0 → \( \mathcal{O}_C^n \) → \( f^*\Omega_{P^r}^n(1) \) → 0 and tensoring it by \( f^*\mathcal{O}_P(1) \), we get a filtration of \( f^*\Omega_{P^r}^n(k + 1) \) by the vector bundles \( \Lambda^u(\mathcal{O}_C^n) \otimes f^*\Omega_H^v(1) \) for \( u + v = k \) and \( u, v \) non negative. By Corollary 2.6, the first cohomology groups of these bundles vanish except maybe for \( v = 0 \) or \( v = r - a \). For \( v = 0 \) we have \( \Lambda^a(\mathcal{O}_C^n) \otimes f^*\Omega_H^v(1) = \Lambda^k(\mathcal{O}_C^n) \otimes f^*\mathcal{O}_P(1) \) and for \( v = r - a \) we have \( \Lambda^a(\mathcal{O}_C^n) \otimes f^*\Omega_H^v(1) = \Lambda^{k+a-r}(\mathcal{O}_C^n) \). The first cohomology group in the first case vanishes while the first cohomology group in the second case has dimension \( \binom{n-a}{r-k} \). We thus have an inequality \( \dim H^1(C, f^*\Omega_{P^r}^n(k + 1)) \leq \binom{n-a}{r-k} \).

For \( a < r - k \), we are done. If \( a \geq r - k \), let us consider the identification \( \Omega_{P^r}^n(k + 1) = (\Omega_{P^r}^{r-k}(r - k))^\vee \). By the above exact sequence, we have a trivial subbundle of rank \( a \) of \( f^*\Omega_{P^r}^{r-k}(1) \) therefore we have a trivial subbundle of rank \( \binom{n-a}{r-k} \) in \( f^*\Omega_{P^r}^{r-k}(r - k) \) (take the \( r - k \) exterior power). By duality, there is a trivial quotient bundle of rank \( \binom{n-a}{r-k} \) of \( f^*\Omega_{P^r}^n(k + 1) \).

**Lemma 2.8** Let \( E \) be a globally generated vector bundle on \( C \) such that \( E \) has a trivial quotient of rank \( n \), then \( \dim H^1(C, E) \geq n \).

**Proof.** By Serre duality we have an isomorphism \( H^1(C, E) \cong H^0(C, E^\vee)^\vee \). We therefore need to prove that \( \dim H^0(C, E^\vee) \geq n \). But we have a surjection \( E \to \mathcal{O}_C^n \), giving rise to an injection \( \mathcal{O}_C^n \to E^\vee \) and the result follows. \( \square \)

We conclude using the previous lemma and because \( \Omega_{P^r}^n(k + 1) \) is globally generated. \( \square \)

### 2.2 Spinor bundles on quadrics

In this section we consider the spinor bundles on quadrics and their restriction to elliptic curves.

**Proposition 2.9** Let \( Q_n \) be a smooth \( n \)-dimensional quadric and let \( E \) be a spinor bundle on \( Q_n \). Let \( f : C \to Q_n \) be a morphism from a smooth irreducible curve to \( Q_n \). Then the pull-back \( f^*E \) is isomorphic to a direct sum \( \mathcal{O}_C^{2^h} \oplus F \) where \( F \) has no trivial factor if and only if \( f \) factors through an isotropic subspace of (linear) dimension \( [n/2] + 1 - \alpha \) with

\[
\alpha = \begin{cases} 
\beta & \text{for } n \text{ odd}, \\
\beta + 1 & \text{for } n \text{ even and } \beta > 0, \\
0 & \text{for } n \text{ even and } \beta = 0
\end{cases}
\]

and in the last case, the maximal isotropic subspace has to be an element of a fixed component of the two connected components of maximal isotropic subspaces.

**Proof.** We shall here use the results of G. Ottaviani [Ott88] on the spinor bundles. Let us write \( h = [n/2] - 1 \) and \( p = [n/2] + 1 \). There is an embedding \( \varphi : Q_n \to G(2^h, 2^{h+1}) \) such that \( E = \varphi^*K \) with \( K \) the tautological subbundle in the Grassmann variety \( G(2^h, 2^{h+1}) \) of \( 2^h \) dimensional subspaces in \( \mathbb{C}^{2^{h+1}} \).
Lemma 2.10 Let $x$ and $y$ be points on $Q_n$, then we have the equality $C^{2h+1} = K_{\varphi(x)} \oplus K_{\varphi(y)}$ if and only if $x$ and $y$ are not orthogonal.

Proof. We shall consider the dual assertion: the map $C^{2h+1} \to K^\vee_{\varphi(x)} \oplus K^\vee_{\varphi(y)}$ is an isomorphism if and only if $x$ and $y$ are not orthogonal. To test this assertion, we can restrict the bundle $K$ to some subvariety containing both $x$ and $y$. If $x$ and $y$ are not orthogonal, then we may choose a smooth conic $c : \mathbb{P}^1 \to Q_n \to G(2^h, 2h+1)$ passing through $x$ and $y$. By [Ott88, Theorem 1.4], the pull back $c^*K^\vee$ is isomorphic to $O_{\mathbb{P}^1}(1)$. The surjectivity condition holds.

Conversely, if $x$ and $y$ are orthogonal, then there exists a maximal isotropic subspace $V_p$ (if $n$ is even we can choose $V_p$ to be in any of the two connected components of maximal isotropic subspaces) such that $x$ and $y$ are contained in $P(V_p)$. By [Ott88, Theorems 2.5 and 2.6] the restriction of $K$ to $P(V_p)$ contains a trivial factor (if $n$ is even this is true only for $V_p$ in one of the two connected components). Therefore the surjectivity condition does not hold. □

Let us return to the proof of the proposition. Remark that $f^*E$ has a trivial factor if and only if for all $x \in C$ the subspaces $K_{\varphi(x)}$ have a common intersection in $C^{2h+1}$. This occurs only if for all $x$ and $y$ in $C$, the points $f(x)$ and $f(y)$ are orthogonal. In particular the linear subspace spanned by $f(C)$ has to be isotropic. Therefore if the curve $f(C)$ is not contained in an isotropic subspaces then $f^*E$ has no trivial factor.

Let us assume that $f^*E$ has a trivial factor. Then $f$ factors through an isotropic subspace $V_p$. Furthermore by [Ott88, Theorems 2.5 and 2.6], we know that the restriction $E_{\mathbb{P}(V_p)}$ is isomorphic to one of the following direct sums (the first case occurs for $n$ odd while the other two cases occur for $n$ even):

$$\bigoplus_{k=0}^p \Omega^k_{\mathbb{P}(V_p)}(k), \bigoplus_{k=0, k \text{ odd}}^p \Omega^k_{\mathbb{P}(V_p)}(k) \text{ or } \bigoplus_{k=0, k \text{ even}}^p \Omega^k_{\mathbb{P}(V_p)}(k).$$

By the previous results on the projective space, we conclude that if $f(C)$ factors through a linear subspace of linear dimension $p - \alpha$ and if there is a unique such factor then $V_p$ is in the connected component of $G_{Q}(p, 2p)$ corresponding to the last decomposition above. The number of trivial factors in $f^*E$ is then $2^\beta$ with $\beta$ and $\alpha$ as above. □

For elliptic curves, applying the same techniques as in the case of the projective space, we obtain the following result.

Corollary 2.11 Let $Q_n$ be a smooth $n$-dimensional quadric and let $E$ be a spinor bundle on $Q_n$. Let $f : C \to Q_n$ be a morphism from a smooth irreducible elliptic curve to $Q_n$. Then we have the equality $\dim H^1(C, f^*E) = 2^\beta$ if and only if $f$ factors through an isotropic subspace of (linear) dimension $[n/2] + 1 - \alpha$. 

Documenta Mathematica 18 (2013) 679–706
with
\[
\alpha = \begin{cases} 
\beta & \text{for } n \text{ odd,} \\
\beta + 1 & \text{for } n \text{ even and } \beta > 0, \\
0 & \text{for } n \text{ even and } \beta = 0
\end{cases}
\]
and in the last case, the maximal isotropic subspace has to be an element of a fixed component of the two connected components of maximal isotropic subspaces.

3 Irreducibility

We are now in position to prove our main result. Let \( C \) be a smooth elliptic curve. We proceed via a case-by-case analysis to finish the proof of Theorem 0.1.

3.1 Projective space

Our proof is based on the fact that the irreducibility of the scheme of morphisms to a projective space is well known. Let us first recall this fact. Let \( X = \mathbb{P}(V) \) with \( V \) of dimension \( n \).

**Fact 3.1** Let \( d \geq 2 \) be an integer, the scheme \( \text{Hom}_d(C, X) \) is irreducible of dimension \( dn \).

**Proof.** The scheme of morphisms is described by simple Brill-Noether data: a line bundle \( \mathcal{L} \) on \( C \) of degree \( d \) and a linear map from \( V^\vee \) to \( H^0(C, \mathcal{L}) \). But for \( d \) positive, we have \( H^1(C, \mathcal{L}) = 0 \) therefore \( H^0(C, \mathcal{L}) \) is of constant dimension \( d \) for all \( \mathcal{L} \) and the result follows from the fact that \( \text{Jac}^d(C) \), the Jacobian of degree \( d \) line bundles on \( C \), is irreducible: the variety \( \text{Hom}_d(C, \mathbb{P}(V)) \) is a locally trivial bundle over \( \text{Jac}^d(C) \) with fiber \( \mathbb{P}(V \otimes H^0(C, \mathcal{L})) \) over \( \mathcal{L} \). \( \square \)

3.2 Grassmann varieties

We now deal with Grassmann varieties. Note that in this case the result was proved by A. Bruguères [Bru87]. We include here a proof that will serve as a model for the other cases. Let \( X \) be the Grassmann variety \( G(p, n) \) of \( p \)-dimensional vector spaces in a vector space of dimension \( n \).

**Proposition 3.2** The scheme \( \text{Hom}_d(C, X) \) is irreducible of dimension \( nd \) for \( d \geq n \).

**Proof.** Consider the open subset \( U \) given by Theorem 1.6. We have a morphism \( \phi : U \to Y \) with \( Y \simeq \mathbb{P}^{n-p} \) which is the vector bundle
\[
E = T_{\mathbb{P}^{n-p}}(-1) \otimes \mathcal{O}_{\mathbb{P}^{n-p}}^{p-1} = (\Omega_{\mathbb{P}^{n-p}}^{n-p-1}(n-p))^{p-1}.
\]
By Proposition 1.1, we only need to prove the irreducibility of the scheme \( \text{Hom}_d(C, U) \). For this we study the map \( \phi \). Let us denote by \( H_a \) the locally
closed subset of $\text{Hom}_d(C,Y)$ of maps whose image is contained in a linear subspace of codimension $a$ and not in a smaller linear subspace. The dimension of this locally closed subset is $a(n - p + 1 - a) + d(n - p + 1 - a)$. Indeed, there is a morphism $H_a \to G(n - p + 1 - a, n - p + 1)$ sending to a morphism the unique linear subspace of codimension $a$ containing its image. The fibers are isomorphic to $\text{Hom}_d(C, \mathbb{P}^{n-p-a})$.

Now the inverse image under the map $\Phi : \text{Hom}_d(C,U) \to \text{Hom}_d(C,Y)$ induced by $\phi$ of $H_a$ is irreducible of dimension $\dim H_a + \dim H^0(C, f^*E)$ for $f \in H_a$. By Proposition 2.7 we have $\dim H^0(C, f^*E) = (d \deg(E) + a)(p-1) = d(p-1) + a(p-1)$. In particular for $d \geq n$, the dimension of $\Phi^{-1}(H_a)$ is $(d + a)(n - a) = dn - a(d - n) - a^2 < dn$ for $a > 0$. The locally closed subsets $\Phi^{-1}(H_a)$ for $a > 0$ are therefore of dimension smaller than the dimensions (at least $dn$) of irreducible components of $\text{Hom}_d(C, U)$ thus the irreducible components of $\text{Hom}_d(\mathbb{P}^1, U)$ are those of $\Phi^{-1}(H_0)$ which is irreducible of dimension $dn$.

**Remark 3.3** For smaller degrees, the scheme $\text{Hom}_d(C,X)$ is not irreducible (except in degree 2). Its irreducible components were described in [Bru87].

### 3.3 Quadrics

We shall now deal with smooth quadrics. Note that in this case the irreducibility of the scheme of morphisms was proved by E. Ballico [Bal89] for quadrics of dimension $n \geq 6$ for curves of genus $g$ with $g \leq \lfloor \frac{n-1}{2} \rfloor$ and for the degree $d \geq 2g - 1$. Let $X$ be a smooth quadric of dimension $n$.

**Proposition 3.4** Assume that $\dim X \neq 3$, then the scheme $\text{Hom}_d(C,X)$ is irreducible of dimension $nd$ for $d \geq 3$.

**Proof.** We proceed as for the Grassmann variety and consider the open subset $U$ given by Theorem 1.6. We have a tower of affine bundles $\phi : U \to Y$ where $Y \simeq \mathbb{P}^r$ with $r = \lfloor n/2 \rfloor$ and the direction vector bundles are the pullbacks of $E = \Omega_{\mathbb{P}^r}^1(2)$ for $n$ even (here $\phi$ is a vector bundle) and to $E = \Omega_{\mathbb{P}^r}^1(2)$ and $E' = \mathcal{O}_{\mathbb{P}^r}(1)$ for $n$ odd.

By Proposition 2.7 the vector bundle $E$ satisfies $H^1(C, f^*E) = 0$ for any map $f : C \to Y$ of degree $d \geq 3$ as soon as $f$ does not factor through a line. In this latter case we have $\dim H^1(C, f^*E) = 1$ and we conclude by Proposition 1.3.

**Remark 3.5** (i) Note that if $\dim X \leq 2$, then $X$ is a product of projective lines and the result follows from that case. However, if $\dim X = 3$, then in the above proof we get $r = 1$ and $\Omega_{\mathbb{P}^2}^1(2) = \mathcal{O}_{\mathbb{P}^2}$, and we do not get the vanishing condition.

(ii) Note that for $d = 2$ the scheme $\text{Hom}_d(C,X)$ is also irreducible but not of the expected dimension since any degree 2 morphism factors through a line. The dimension is $2n + 1$. 

*Documenta Mathematica* 18 (2013) 679–706
Even if we cannot prove, with our method, Proposition 3.4 when $X$ is 3-dimensional, the result is still true.

**Proposition 3.6** Let $X = \mathbb{Q}^3$ be a smooth quadric of dimension 3, then the scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $3d$ for $d \geq 3$.

We give a proof of this result for $d \geq 4$ in the appendix, using a different method. The case where $d = 3$ is given by the following remark.

**Remark 3.7** Any morphism of degree 2 or 3 from an elliptic curve to $\mathbb{Q}^3$ has to factor through a line. This is clear for degree 2, and for degree 3 the morphism factors through a plane. But as $\mathbb{Q}^3$ contains no plane, the image is contained in the intersection of $\mathbb{Q}^3$ with a plane. It has to be a line for degree reasons. In particular the scheme of morphisms $\text{Hom}_d(C, X)$ is irreducible of dimension $3 + 2d$ for $d = 2$ or $d = 3$.

### 3.4 Maximal orthogonal Grassmann varieties

Let $X$ be a maximal orthogonal Grassmann variety $G_{\mathbb{Q}}(n, 2n)$. The following result already appeared in the work of the second author [Per12] where it was proved by a different method.

**Proposition 3.8** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $2(n - 1)d$ for $d \geq n - 1$.

**Proof.** The map $\phi : U \to Y$ is the vector bundle $E = \Lambda^2(T_{\mathbb{P}^{n-1}}(-1)) = \mathcal{O}_{\mathbb{P}^{n-1}}^{n-3}(n - 2)$ over $Y \simeq \mathbb{P}^{n-1}$. By Proposition 2.7, the fibers of $\Phi : \text{Hom}_d(C, U) \to \text{Hom}_d(C, Y)$ over the locally closed subset $H_a$ of morphisms whose image is non-degenerate in a linear subspace of codimension $a$ are of dimension $d(n - 2) + \binom{n}{2}$. Therefore we have $\dim p^{-1}(H_a) = 2d(n - 1) + a(n - a) + \binom{n}{2} - ad$. This dimension is strictly smaller than the expected dimension $2d(n - 1)$ for $a > 0$ and $d \geq n - 1$. The result follows. □

**Corollary 3.9** For $d \in [2, n]$, the scheme $\text{Hom}_d(C, X)$ is irreducible of dimension

$$2(n - 1)d + \frac{1}{2}(n - d)(n - d - 1).$$

**Proof.** Let $f : C \to X$ be a morphism of degree $d$, then the kernel $\ker(f)$ of $f$ i.e. the intersection of all subspaces $f(x)$ for $x \in C$ is of dimension at least $n - d$ (see [Buc03] for other applications of this definition). Indeed, consider the tautological exact sequence

$$0 \to K \to \mathcal{O}_X^{2n} \to Q \to 0$$

on $X$ where $K$ and $Q$ are the tautological subbundle and quotient bundle. On $X$ we have the identification $Q \simeq K^\vee$. Pulling back this sequence to $C$ via $f$ we get an exact sequence on the curve. Taking cohomology we obtain:

$$0 \to H^0(C, K) \to \mathcal{C}^{2n} \to H^1(C, K) \to H^1(C, K) \to \mathcal{C}^{2n} \to H^0(C, K) \to 0.$$
Let us denote by $h^0$ and $h^1$ the dimensions of $H^0(C, K)$ and $H^1(C, K)$. Since the map $f$ is of degree $d$ in $X$, the degree of $K$ is $-2d$ and we have the equality $h^0 = h^1 - 2d$. We deduce the inequality $h^0 \geq n - d$. This implies that $\ker(f)$ is of dimension at least $n - d$. Note also that for a general curve the kernel is of dimension exactly $n - d$.

Let us consider the following incidence variety $I = \{(f, V_{n-d}) \in \text{Hom}_d(C, X) \times \mathcal{G}_Q(n - d, 2n) / \text{ for all } x \in C \text{ we have } V_{n-d} \subset f(x) \subset V_{n-d}^\perp\}$. Here $\mathcal{G}_Q(n - d, 2n)$ is the Grassmann variety of isotropic subspaces of $\mathbb{C}^{2n}$ of dimension $n - d$. The above condition on $f$ simply translates in $V_{n-d} \subset \ker(f)$. Note that the second inclusion is implied by the first one since we have $f(x) = f(x)^\perp$. The projection $p : I \to \text{Hom}_d(C, X)$ is surjective and birational (because for a general curve the kernel is of dimension $n - d$) while the map $q : I \to \mathcal{G}_Q(n - d, 2n)$ is an equivariant locally trivial fibration with fibers $\text{Hom}_d(C, Y)$ with $Y \simeq \mathcal{G}_Q(d, 2d)$. By the previous proposition these fibers are irreducible of dimension $2d(d - 1)$. The result follows. □

3.5 Adjoint varieties of type B and D

Let us consider the variety $X = \mathcal{G}_Q(2, n)$ of isotropic planes in a vector space of dimension $n$ endowed with a non-degenerate bilinear form.

**Proposition 3.10** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $(n - 3)d$ for $d \geq n - 1$.

**Proof.** The map $\phi : U \to Y$ is the vector bundle $E = (\mathcal{O}_{\mathbb{P}^{n-4}}(1))^\perp$ over $Y \simeq \mathbb{Q}_{n-4}$, where $\mathcal{O}_{\mathbb{P}^{n-4}}(-1)$ is the tautological subbundle on $\mathbb{Q}_{n-4}$.

Here we have to compute the dimension of the scheme of morphisms from an elliptic curve to a cone (the intersection of $\mathbb{Q}_{n-4}$ with a linear subspace of $\mathbb{P}^{n-3}$ in our case). Let $\mathfrak{C}$ be a cone in $\mathbb{P}^{k+r-1}$ associated to a quadratic form of rank $r$ (and therefore with kernel $K$ of dimension $k$).

**Lemma 3.11** Consider the open subset in the scheme of degree $d$ morphisms from an elliptic curve $C$ to $\mathfrak{C}$ consisting of morphisms whose image is non-degenerate. Then this open subset is of dimension at most $d(k + r - 2)$.

Remark that, if $k = 0$, the cone $\mathfrak{C}$ is a smooth quadric of dimension $(k + r - 2)$ and we already know the result with equality.

**Proof.** Consider the incidence variety $I = \{(V_1, V_{k+1}) \in \mathfrak{C} \times \mathcal{G}_Q(k + 1, k + r) / V_1 \subset V_{k+1} \supset K\}$. There is a diagram

$$
\begin{array}{ccc}
I & \xrightarrow{p} & \mathcal{G}_{r-2} \\
\downarrow q & & \\
\mathfrak{C} & \end{array}
$$

**Documenta Mathematica 18 (2013) 679–706**
The map $q$ is simply the blow-up of the vertex of the cone. If $f : C \to \mathcal{C}$ has a non degenerate image then its image is not contained in the vertex $\mathbb{P}(K)$ of the cone and we may consider the composition of $f$ with the projection from $K$. This defines a morphism $f' : C \to \mathbb{Q}_{r-2}$ which can be obtained by lifting $f$ to $f_I : C \to I$ and composing with $p$. The degree of this morphism is $d - x$ where $x$ is the multiplicity of the intersection of $f(C)$ with the vertex of the cone.

To compute the dimension of our open set, we consider the map defined by $f \mapsto f'$. Its image is contained in $\text{Hom}_{d-a}(\mathcal{C}, \mathbb{Q}_{r-2})$ which is of dimension $(d - x)(r - 2)$. The fiber is given by the morphisms $\mathcal{L} \to f''V_{k+1}$ where $\mathcal{L}$ is of degree $d$ and $V_{k+1}$ is the tautological subbundle in $\mathbb{Q}_{r-2} \simeq \{V_{k+1} \in \mathcal{G}_Q(k+1,k+r) / K \subset V_{k+1}\}$. Because the projection by $K$ gives a curve of degree $d - x > 0$ we have an extension $0 \to K \otimes \mathcal{O}_C \to f''V_{k+1} \to \mathcal{L}' \to 0$ with $\mathcal{L}'$ of degree $d - x$. This extension has to split, thus the fibers of the map are given by $\text{Pic}(\mathcal{L}, K \otimes \mathcal{O}_C \oplus \mathcal{L}')$ which is of dimension $kd + x$. The dimension is therefore at most $d(k + r - 2) - x(r - 3)$ proving the result for $r \geq 3$. But if $r \leq 2$, then the cone is a union of hyperplanes, thus the curve is degenerate.

By Proposition 2.7, since $E$ is the restriction to $\mathbb{Q}_{n-4}$ of $\Omega_{\mathbb{P}^{n-3}}^n(n-3)$, the fibers of $\Phi : \text{Hom}_d(\mathcal{C}, U) \to \text{Hom}_d(\mathcal{C}, Y)$ over the locally closed subset $H_a$ of morphisms whose image is non-degenerate in a linear subspace of codimension $a$ are of dimension $d + a$. Therefore the dimension of $\Phi^{-1}(H_a)$ is at most the sum of $d + a$, the dimension of the Grassmann variety $\mathcal{G}(n - 2 - a, n - 2)$ and the dimension of the scheme of degree $d$ morphisms from an elliptic curve $C$ to a cone $\mathcal{C}$ in $\mathbb{P}^{n-3-a}$, so that $\dim \Phi^{-1}(H_a) \leq d(n - a - 3) + a(n - 2 - a) + a$. This dimension is strictly smaller than the expected dimension $(n - 4)d$ for $a > 0$ and $d \geq n - 1$. The result follows.

Remark 3.12 The above argument shows that for $d = n - 2$, the scheme of morphisms has 2 irreducible components of the expected dimension.

3.6 Type $E_6$

3.6.1 Cayley plane

Let $X$ be isomorphic to $E_6/P_1$.

Proposition 3.13 The scheme $\text{Hom}_d(\mathcal{C}, X)$ is irreducible of dimension $12d$ for $d \geq 3$.

Proof. The map $\phi : U \to Y$ is one of the two spinor bundles $S$ over $Y \simeq \mathbb{Q}_8$. By Corollary 2.11, the fibers of $p : \text{Hom}_d(\mathcal{C}, U) \to \text{Hom}_d(\mathcal{C}, Y)$ over the locally closed subset $H_a$ of morphisms whose image is non degenerate in an isotropic linear subspace of codimension $a$ are of dimension $4d + 2^{\text{max}(0,a-6)}$ with $a \geq 5$. Therefore we have the equality $\dim \Phi^{-1}(H_a) = 12d + a(10 - a) - \frac{(10-a)(11-a)}{2} + 2^{\text{max}(0,a-6)} - ad$. This dimension is strictly smaller than the expected dimension $12d$ for $a > 0$ and $d \geq 3$. The result follows.
3.6.2 Adjoint variety

Let $X$ be isomorphic to $E_8/P_2$.

**Proposition 3.14** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $11d$ for $d \geq 9$.

**Proof.** The map $\phi : U \to Y$ is a tower of affine bundles over $Y \simeq \mathbb{Q}_6$ with direction vector bundles $E = (\mathcal{O}_{\mathbb{Q}_6}(1))^\perp$ (where $\mathcal{O}_{\mathbb{Q}_6}(-1)$ is the tautological subbundle on $\mathbb{Q}_6$) and $E' = S \oplus S'$ where $S$ and $S'$ are the two spinor bundles on $\mathbb{Q}_6$. Note that the bundle $E$ is the restriction of the tautological quotient bundle of $P_7$ to $\mathbb{Q}_6$. By Proposition 2.7 and Corollary 2.11, the fibers of $\Phi : \text{Hom}_d(C, U) \to \text{Hom}_d(C, Y)$ over the locally closed subset $H_a$ of morphisms whose image is non degenerate in a linear subspace of codimension $a$ are of dimension at most $5d + a$ for $a \leq 3$ or $a \geq 4$ and the subspace containing the curve is non isotropic and $5d + a + 2^{\max(0, a-4)}$ for $a \geq 4$ and the subspace containing the curve is isotropic. Therefore we have the equality $\dim \Phi^{-1}(H_a) = d(11 - a) + a(8 - a) + a$ for $a \leq 3$ or $a \geq 4$ and the subspace containing the curve is non isotropic and $d(13 - a) + a(8 - a) - \frac{(5-a)(a-6)}{2} + a + 2^{\max(0, a-4)}$ for $a \geq 4$ and the subspace containing the curve is isotropic. This dimension is strictly smaller than the expected dimension $11d$ for $a > 0$ and $d \geq 9$. The result follows. □

3.7 Type $E_7$

3.7.1 Freudenthal variety

Let $X$ be isomorphic to $E_7/P_7$.

**Proposition 3.15** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $18d$ for $d \geq 8$.

**Proof.** The map $\phi : U \to Y$ is a tower of affine bundles with direction vector bundles $E = \Omega^6_{\mathbb{P}_6}(6)$ and $E' = \Omega^3_{\mathbb{P}_6}(3)$. By Proposition 2.7, the fibers of $\Phi : \text{Hom}_d(C, U) \to \text{Hom}_d(C, Y)$ over the locally closed subset $H_a$ of morphisms whose image is non degenerate in a linear subspace of codimension $a$ are of dimension at most $11d + a + \left(\begin{smallmatrix}a \\ 2\end{smallmatrix}\right)$. Therefore we have $\dim \Phi^{-1}(H_a) = 18d + a(7 - a) + a + \left(\begin{smallmatrix}a \\ 3\end{smallmatrix}\right) - ad$. This dimension is strictly smaller than the expected dimension $18d$ for $a > 0$ and $d \geq 8$. The result follows. □

3.7.2 Adjoint variety

Let $X$ be isomorphic to $E_7/P_1$.

**Proposition 3.16** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $17d$ for $d \geq 11$. 

*Documenta Mathematica 18 (2013) 679–706*
Proposition 3.17 The scheme $\text{Hom}_d(C, U) \rightarrow \text{Hom}_d(C, Y)$ over the locally closed subset $H_d$ of morphisms whose image is non degenerate in a linear subspace of codimension $a$ are of dimension at most $9d + a$ for $a \leq 4$ or $a \geq 5$ and the subspace containing the curve is non isotropic and $9d + a + 2^{\max(0, a - 6)}$ for $a \geq 5$ and the subspace containing the curve is isotropic. Therefore we have the equality $\dim \Phi(H_d) = d(17 - a) + a(10 - a) + a$ for $a \leq 4$ or $a \geq 5$ and the subspace containing the curve is non isotropic and $d(19 - a) + a(10 - a) - \frac{(10 - a)(11 - a)}{2} + a + 2^{\max(0, a - 6)}$ for $a \geq 5$ and the subspace containing the curve is isotropic. This dimension is strictly smaller than the expected dimension $17d$ for $a > 0$ and $d \geq 11$. The result follows.

3.8 Adjoint variety of type $E_8$

Let $X$ be isomorphic to $E_8/P_8$.

**Proposition 3.17** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $29d$ for $d \geq 15$.

Proof. The map $\phi : U \rightarrow Y$ is a tower of affine bundles over $Y \simeq \mathbb{Q}_8$ with direction vector bundles $E = (\mathcal{O}_{\mathbb{Q}_8}(1))^\perp$ where $\mathcal{O}_{\mathbb{Q}_8}(-1)$ is the tautological subbundle on $\mathbb{Q}_8$ and $E' = S^2$ where $S$ is one of the two spinor bundles on $\mathbb{Q}_8$. By Proposition 2.7 and Corollary 2.11, the fibers of $\Phi : \text{Hom}_d(C, U) \rightarrow \text{Hom}_d(C, Y)$ over the locally closed subset $H_d$ of morphisms whose image is irreducible of dimension $29d$ for $d \geq 15$.

3.9 Adjoint variety of type $F_4$

Let $X$ be isomorphic to $F_4/P_1$.

**Proposition 3.18** The scheme $\text{Hom}_d(C, X)$ is irreducible of dimension $11d$ for $d \geq 8$.

Proof. The map $\phi : U \rightarrow Y$ is a tower of affine bundles over $Y \simeq \mathbb{Q}_8$ with direction vector bundles $E = (\mathcal{O}_{\mathbb{Q}_8}(1))^\perp$ where $\mathcal{O}_{\mathbb{Q}_8}(-1)$ is the tautological subbundle on $\mathbb{Q}_8$ and $E' = S$ where $S$ is the spinor bundle on $\mathbb{Q}_8$. By Proposition 2.7 and Corollary 2.11, the fibers of $\Phi : \text{Hom}_d(C, U) \rightarrow \text{Hom}_d(C, Y)$
over the locally closed subset $H_a$ of morphisms whose image is non degenerate in a linear subspace of codimension $a$ are of dimension at most $6d + a$ for $a \leq 3$ or $a \geq 4$ and the subspace containing the curve is non isotropic and $6d + a + 2\max(0, a - 5)$ for $a \geq 4$ and the subspace containing the curve is isotropic. Therefore we have the equality $\dim \Phi^{-1}(H_a) = d(11 - a) + a(7 - a) + a$ for $a \leq 3$ or $a \geq 4$ and the subspace containing the curve is non isotropic and $d(13 - a) + a(7 - a) - \frac{(7 - a)(8 - a)}{2} + a + 2\max(0, a - 5)$ for $a \geq 4$ and the subspace containing the curve is isotropic. This dimension is strictly smaller than the expected dimension $11d$ for $a > 0$ and $d \geq 8$. The result follows.

**Remark 3.19** Note that, in Propositions 3.14, 3.15, 3.16, 3.17 and 3.18, it is possible that one can improve the bound on the dimension of $\Phi^{-1}(H_a)$. Indeed if the affine bundle restricted to a curve in $H_a$ is not a vector bundle then this bound will be strictly smaller. We therefore expect a better bound $d(X)$ in these situations.

4 Stable maps

Let us consider the moduli space $\overline{M}_{1,d}(X)$ of stable maps with source an elliptic curve. Recall the following general result obtained in [KP01].

**Theorem 4.1** ([KP01]) The moduli space $\overline{M}_{1,d}(X)$ is connected for any rational homogeneous space $X$ and any degree $d$.

Note, in contrast, that for any $X$ in the tables of the introduction, we have the proposition.

**Proposition 4.2** For $d \geq d(X)$, the moduli space $\overline{M}_{1,d}(X)$ is never irreducible.

**Proof.** Indeed, consider the locally closed subset of $\overline{M}_{1,d}(X)$ where the degree on the unique elliptic irreducible component of the source of the map is 2. The dimension of this locally closed subset is $dc_1(X) + \dim X$ which is always strictly bigger than the expected dimension $dc_1(X)$ which is the dimension of the component containing irreducible curves for $d \geq d(X)$. □

However, there is a natural decomposition of this space into locally closed subsets $M^\tau_{1,d_\tau}(X)$ parametrised by their combinatorial graph $\tau$ and combinatorial degree $d_\tau$ (see [KM94] or also [KP01]). Note that for stable maps of genus one, at most one irreducible component of the source map is an elliptic curve. We call this component (if it exists) the elliptic component of $\tau$. As a consequence of our results we obtain the following proposition.

**Proposition 4.3** If the degree $d_\tau$ is bigger that $d(X)$ on the elliptic component of $\tau$, then $M^\tau_{1,d_\tau}(X)$ is irreducible.
Proof. If there is no elliptic component, then the result follows from the fact (see [BCMP10]) that the moduli space of stable maps of genus 0 passing through at most 2 fixed points is irreducible for any homogeneous space $X$.

If there is an elliptic component, then we claim that the natural forgetful map to the moduli space of elliptic curves is flat with irreducible fibers. Indeed, the fiber over $C$ is isomorphic to the product of $\text{Hom}_d(C, X)$ with some moduli spaces of rational stable maps passing through at most 2 fixed points. These last moduli spaces are irreducible of the expected dimension by [BCMP10, Corollary 3.3]. Now by dimension count, any irreducible component of $M^\tau_d(X)$ has to dominate the moduli space of elliptic curves (the fibers have constant dimension 1 less than the expected dimension) thus the map is flat. The result follows by [Gro65, Corollaire 2.3.5.(ıı)].

□

A The quadric of dimension 3

In this section, we prove Proposition 3.6 for $d \geq 4$ using Bott-Samelson resolutions (the reader could see [Dem74] for more details on Bott-Samelson resolutions). This method was already used by the second author in [Per12] to study elliptic curves in spinorial varieties.

First we introduce some notation. Let $V$ be a 5-dimensional vector space endowed with a non degenerate quadratic form $Q$. Then $X$ is the subvariety of $P(V)$ consisting of isotropic lines in $V$.

For any isotropic flag $W_\bullet = (W_1, W_2)$ of $V$, we define a Bott-Samelson resolution $\pi : \tilde{X} \rightarrow X$ by

$$\tilde{X} = \tilde{X}_{W_\bullet} = \{(V'_1, V_2, V_1) \in \mathbb{Q}_3 \times \mathbb{G}_Q(2, 5) \times \mathbb{Q}_3 \mid V'_1 \subset W_2, V'_1 \subset V_2, V_1 \subset V_2\},$$

and $\pi(V'_1, V_2, V_1) = V_1$. The map $\pi$ is birational, in particular it is an isomorphism over the open $B$-orbit of $X$, where $B$ is the Borel subgroup of $\text{SO}(5)$ associated to $W_\bullet$. Moreover if we define $X_0 = \{\text{pt}\}$, $X_1 = \{V'_1 \in \mathbb{Q}_3 \mid V'_1 \subset W_2\}$ $X_2 = \{(V'_1, V_2) \in \mathbb{Q}_3 \times \mathbb{G}_Q(2, 5) \mid V_2 \supset V'_1 \subset W_2\}$ and $X_3 = \tilde{X}$, there is sequence of $\mathbb{P}^1$-bundles

$$\tilde{X} = X_3 \rightarrow X_2 \rightarrow X_1 \rightarrow X_0 = \{\text{pt}\}.$$ 

The proof of Proposition 3.6 uses the 3 following facts.

Fact 1 Under some conditions $(*)_d$ on the class $\tilde{\alpha}$ of 1-cycles in $\tilde{X}$ (see Definition A.4), the scheme $\text{Hom}_d(C, \tilde{X})$ of morphisms from $C$ to $\tilde{X}$ of class $\tilde{\alpha}$ is irreducible of dimension at most $3d - 1$ with equality for a unique class $\tilde{\alpha}$.

Fact 2 For all $f \in \text{Hom}_d(C, X)$ such that $f(C)$ is not contained in an isotropic projective line of $P(V)$, we can choose a flag $W_\bullet$ such that $f$ lifts into a unique $\tilde{f} : C \rightarrow \tilde{X}_{W_\bullet}$, such that $\tilde{\alpha} := [\tilde{f}_*(C)]$ satisfies the conditions $(*)_d$. And, for each such $f$, the set of flags that we can choose is a subvariety (not closed) of $\text{SO}(5)/B$ of dimension 3.
Fact 3 For $d \geq 4$ we prove that the scheme of morphisms from $C$ to $X$ of degree $d$ such that $f(C)$ is contained in an isotropic projective line of $\mathbb{P}(V)$ cannot be an irreducible component of $\text{Hom}_d(C, X)$. Assuming these facts for the moment, let us prove Proposition 3.6. Let $I$ be the set of couples $(W_\bullet, f) \in \text{SO}(5)/B \times \text{Hom}_n(C, \tilde{X}_{W_\bullet})$ where $\text{Hom}_n(C, \tilde{X}_{W_\bullet})$ is the scheme of morphisms $\tilde{f}$ from $C$ to $\tilde{X}_{W_\bullet}$ such that $[\tilde{f}_*(C)]$ satisfies $(*)_{d}$. Call $p$ and $q$ the natural projections from $I$ to $\text{Hom}_d(C, X)$ and to $\text{SO}(5)/B$ respectively. Then, by the second and third facts, $p$ is dominant as soon as $d \geq 4$ and general fibers of $p$ have dimension 3. Now, for any flag $W_\bullet$, the fiber $q^{-1}(W_\bullet)$ is the disjoint union, over the $\tilde{\alpha}$ satisfying conditions $(*)_d$, of the schemes $\text{Hom}_d(C, \tilde{X}_{W_\bullet})$ of morphisms $\tilde{f}$ from $C$ to $\tilde{X}_{W_\bullet}$ such that $[\tilde{f}_*(C)] = \tilde{\alpha}$. By the first fact, exactly one of these latter schemes has maximal dimension $3d - 1$ and moreover this scheme is irreducible, so that the fiber $q^{-1}(W_\bullet)$ is irreducible. Thus $I$ is a union of irreducible connected components of dimension at most $3d - 1 + 3d + 3$ with equality for a unique component. The images in $\text{Hom}_d(C, X)$ of these components are irreducible of dimension at most $3d + 3 - 3 = 3d$ which is the expected dimension. Therefore all these images are contained in the closure of the image of the maximal one proving the irreducibility. Moreover the dimension of $\text{Hom}_d(C, X)$ is therefore $4 + (3d - 1) - 3 = 3d$.

Let us prove the three facts one by one. We begin with a general lemma.

**Lemma A.1** Let $\phi : X \to Y$ be a $\mathbb{P}^1$-fibration with a section $\sigma$. Let $\tilde{\alpha}$ be a class of 1-cycles in $X$. Denote by $T_\phi$ the relative tangent bundle and by $\xi$ the divisor $\sigma(Y)$. Suppose that $\tilde{\alpha} \cdot \xi \geq 0$ and that $\tilde{\alpha} \cdot (T_\phi - \xi) > 0$. Then, if $\text{Hom}_{\tilde{\alpha}, \phi}(C, Y)$ is irreducible, $\text{Hom}_{\tilde{\alpha}}(C, X)$ is also irreducible, and

$$\dim(\text{Hom}_{\tilde{\alpha}}(C, X)) = \dim(\text{Hom}_{\tilde{\alpha}, \phi}(C, Y)) + \tilde{\alpha} \cdot T_\phi.$$ 

**Proof.** Let $E$ be a rank two vector bundle on $Y$ such that $X = \mathbb{P}_Y(E)$. The section $\sigma$ is given by a surjection $E \to L$ where $L$ is an invertible sheaf on $Y$. Let $N$ be the kernel of this map. We first study the fiber of the map $\text{Hom}_{\tilde{\alpha}}(C, X) \to \text{Hom}_{\tilde{\alpha}, \phi}(C, Y)$ given by composition of morphisms over a morphism $f : C \to Y$. An element in this fiber is given by a lift of $f$ i.e. a surjective map $f^* E \to M$ of vector bundles on $C$ where $M$ is an invertible sheaf with $2 \deg(M) - \deg(f^* E) = \tilde{\alpha} \cdot T_\phi$. An element in the fiber is therefore given by an invertible sheaf $M$ on $C$ with degree $d = \frac{1}{2}(\deg(f^* E) + \tilde{\alpha} \cdot T_\phi)$ and a surjective map in $\mathbb{P}(\text{Hom}(f^* E, M))$. Note that we have the equalities $\tilde{\alpha} \cdot \xi = \deg(M) - \deg(f^* N)$ and $\tilde{\alpha} \cdot (T_\phi - \xi) = \deg(M) - \deg(f^* L)$. We discuss two cases.

If $\tilde{\alpha} \cdot \xi > 0$ then $\text{Hom}(f^* E, M)$ is isomorphic to $\text{Hom}(f^* N, M) \oplus \text{Hom}(f^* L, M)$ and its dimension $\tilde{\alpha} \cdot T_\phi$ does not depend on $f$. For any invertible sheaf $M$, there exist surjections $f^* E \to M$ and they form an open subset of $\text{PHom}(f^* E, M) \times \text{Pic}_d(C)$. Doing this construction in family as in [Per02, Proposition 4] we get...
a smooth fibration or relative dimension $\alpha \cdot T_0$ over $\text{Hom}_{E,M}(C,Y)$ and the result follows.

If $\alpha \cdot \xi = 0$, then if $M \not= f^*N$ we have $\text{Hom}(f^*N, M) = 0$ and any map $f^*E \to M$ factors through $f^*L$ and is never surjective because $\text{deg}(M) - \text{deg}(f^*L) = \alpha \cdot (T_0 - \xi) > 0$. Therefore any pair $(M, p : f^*E \to M)$ of the fiber satisfies $M \simeq f^*N$. In that case, because of the equality $\text{deg}(M) - \text{deg}(f^*L) = \alpha \cdot (T_0 - \xi) > 0$, the sheaf $f^*E$ is isomorphic to $M \oplus f^*L$ and we have an isomorphism $\text{Hom}(f^*E, M) \simeq \text{Hom}(f^*N, M) \oplus \text{Hom}(f^*L, M)$. The dimension of $\text{Hom}(f^*E, M)$ is $\alpha \cdot T_0 + 1$ and does not depend on $f$. The fiber is therefore a non empty open subset of $\text{FHom}(f^*E, M)$. We therefore again get a smooth fibration of relative dimension $\alpha \cdot T_0$ over $\text{Hom}_{E,M}(C,Y)$. 

Applying this lemma to the $\mathbb{P}^1$-fibrations $\phi_i : X_i \to X_{i-1}$ for $i \in \{1, 2, 3\}$ given above by a Bott-Samelson resolution $\tilde{X}$ of $\mathcal{Q}_3$, we obtain the following corollary. We denote by $T_i$ the relative tangent space of $\phi_i$, we define three divisors $\xi_1$, $\xi_2$, $\xi_3$ of $\tilde{X}$, which are given by natural sections of the $\phi_i$, by

$$\xi_1 = \{(V'_1, V_2, V_1) \in \tilde{X} \mid V'_1 = W_1\}$$
$$\xi_2 = \{(V'_1, V_2, V_1) \in \tilde{X} \mid V_2 = W_2\}$$
$$\xi_3 = \{(V'_1, V_2, V_1) \in \tilde{X} \mid V_1 = V'_1\}.$$

We will again denote by $T_i$ the pull-back of $T_i$ under the morphisms $\phi_j$ for $j > i$.

**Corollary A.2** Let $\alpha$ be a class of 1-cycles in $\tilde{X}$ satisfying for all $i \in \{1, 2, 3\}$, $\alpha \cdot \xi_i \geq 0$ and $\alpha \cdot (T_i - \xi_i) > 0$.

Then $\text{Hom}_{\tilde{X}}(C, \tilde{X})$ is irreducible of dimension $\alpha \cdot (T_1 + T_2 + T_3)$.

To obtain the first fact, we use the following result that can be deduced from [Per05, Corollary 3.8 and Fact 3.7] by a short computation.

**Proposition A.3** (i) The relative tangent bundles $T_i$ are expressed in terms of the $\xi_i$ as follows:

$$T_1 = 2\xi_1, \quad T_2 = 2\xi_2 + \xi_1 \quad \text{and} \quad T_3 = 2\xi_3 + 2\xi_2.$$

In particular, we have $\alpha \cdot \xi_i \geq 0$ and $\alpha \cdot (T_i - \xi_i) > 0$ for all $i \in \{1, 2, 3\}$ as soon as $\alpha \cdot \xi_1 > 0$, $\alpha \cdot \xi_2 > 0$ and $\alpha \cdot \xi_3 \geq 0$, or $\alpha \cdot \xi_1 > 0$, $\alpha \cdot \xi_2 \geq 0$ and $\alpha \cdot \xi_3 > 0$.

(ii) The pull-back $\pi^*\mathcal{Q}_3(1)$ of the ample generator of the Picard group of $\mathcal{Q}_3$ equals $\xi_1 + 2\xi_2 + \xi_3$. In particular, if $\alpha = \pi^*(\alpha)$ where $\alpha$ is the class of 1-cycles of degree $d$ in $\mathcal{Q}_3$, we have $d = \alpha \cdot (\xi_1 + 2\xi_2 + \xi_3)$.

**Definition A.4** We say that $\alpha$ satisfies conditions $(\ast)_d$ if

- $\alpha \cdot \xi_1 > 0$, $\alpha \cdot \xi_2 > 0$ and $\alpha \cdot \xi_3 \geq 0$, or $\alpha \cdot \xi_1 > 0$, $\alpha \cdot \xi_2 \geq 0$ and $\alpha \cdot \xi_3 > 0$;
- $d = \alpha \cdot (\xi_1 + 2\xi_2 + \xi_3)$. 

Documenta Mathematica 18 (2013) 679–706
Remark that, under conditions (\(\ast\))\(_d\), we have \(\hat{\alpha} \cdot (T_1 + T_2 + T_3) = 3d - \hat{\alpha} \cdot (2\xi_2 + \xi_3)\) and then the dimension of the scheme \(\text{Hom}_d(C, \bar{X})\) is at most \(3d - 1\) with equality if an only if \(\hat{\alpha} \cdot \xi_1 = d - 1\), \(\hat{\alpha} \cdot \xi_2 = 0\) and \(\hat{\alpha} \cdot \xi_3 = 1\). We deduce the first fact from above results.

To prove the second fact, fix a curve \(f \in \text{Hom}_d(C, \mathbb{Q}_3)\) such that \(f(C)\) is not contained in an isotropic projective line of \(\mathbb{P}(V)\). We begin by proving the following lemma. If \(E\) is a vector subspace of \(V\), we denote by \(E^\perp\) the orthogonal subspace to \(E\) in \(V\) (with respect to \(Q\)). For any point \(x\) in \(\mathbb{P}(V)\), we denote by \(\pi\) the corresponding line in \(V\).

**Lemma A.5** There exist 3 points \(x_0, x_1, x_2\) of \((f(C)\) and an isotropic flag \(W_* = (W_1, W_2)\) such that \(\pi_0\) is not contained in \(W_1^\perp\), \(\pi_1\) is contained in \(W_1^\perp\) but not in \(W_2\), and \(\pi_2\) is contained in \(W_2\).

**Proof.** First remark that, because \(f(C) \subset \mathbb{Q}_3\), the condition saying that \(f(C)\) is not contained in an isotropic projective line of \(\mathbb{P}(V)\) means that \(f(C)\) is not contained in a projective line of \(\mathbb{P}(V)\).

Then there exist 3 non-collinear points \(x_0, x_1, x_2\) in \(f(C)\). Let \(E := \pi_1^\perp \oplus \pi_2^\perp\) and \(F := \pi_1^\perp \oplus \pi_2\). We can assume that \(Q|_F\) is non-degenerate, in particular \(V = F \oplus F^\perp\) and \(Q\) is non-degenerate on \(F^\perp\). Then there exists an isotropic line \(W_1\) in \(F^\perp\setminus E^\perp\). And we can define \(W_2 = W_1 \oplus \pi_2\), because \(\pi_2 \subset F^\perp\).

It is obvious that \(\pi_2\) is contained in \(W_2\). And we can also easily check that \(\pi_0\) is not contained in \(W_1^\perp\) and that \(\pi_1\) is contained in \(W_1^\perp\) but not in \(W_2\). \(\square\)

**Corollary A.6** There exists a flag \(W_*\) such that \(f\) lifts into a unique \(\tilde{f} : C \to \tilde{X}_{W_*}\), and \([\tilde{f}_*(C)]\) satisfies the conditions (\(\ast\))\(_d\).

**Proof.** Let \(W_*\) be an isotropic flag and \((x_0, x_1, x_2) \in f(C)^3\) as in Lemma A.5. Denote by \(B\) the Borel subgroup of \(\text{SO}(5)\) corresponding to \(W_*\). Then the open \(B\)-orbit \(\Omega\) in \(\mathbb{Q}_3\) is the set of points \(x\) such that \(\pi\) is not contained in \(W_1^\perp\).

Recall that, over \(\Omega\), the morphism \(\pi : \tilde{X}_{W_*} \to \mathbb{Q}_3\) is an isomorphism. Thus, since \(C\) is smooth and \(f(C)\) intersects \(\Omega\) (at least in \(x_0\)), \(f\) lifts into a unique \(\tilde{f} : C \to \tilde{X}_{W_*}\).

Moreover, we can compute that \(\pi(\xi_1) = \{ x \in \mathbb{Q}_3 \mid \pi \subset W_1^\perp \}\) and \(\pi(\xi_2) = \pi(\xi_3) = \{ x \in \mathbb{Q}_3 \mid \pi \subset W_2 \}\). So, for any \(i \in \{1, 2, 3\}\), \(\pi^{-1}(\Omega)\) does not intersect \(\xi_i\) so that \([\tilde{f}_*(C)] \cdot \xi_i \geq 0\). Also, the existence of \(x_1\) implies that \([\tilde{f}_*(C)] \cdot \xi_1 > 0\) and the existence of \(x_2\) implies that \([\tilde{f}_*(C)] \cdot \xi_2 > 0\) or \([\tilde{f}_*(C)] \cdot \xi_3 > 0\). \(\square\)

Let us now explain why the set of flags that we can choose is of dimension 3. In the proof of Lemma A.5, we can note that, when \(x_0, x_1, x_2\) are fixed in \(f(C)^3\), we choose \(W_1\) in a quadric of dimension 1 and \(W_2\) is uniquely determined. Moreover, if \(W_*\) is fixed, then we have finitely many choices for \(x_1\) and \(x_2\) whereas the set of possible \(x_0\) is one-dimensional. At the end, the dimension we are looking for is \(3 + 1 - 1 = 3\).
Finally, let us prove the third fact. Let $J$ be the scheme of morphisms from $C$ to $X$ of degree $d$ such that $f(C)$ is contained in an isotropic projective line of $\mathbb{P}(V)$. We have a natural projection from $J$ to the variety $G_Q(2,5)$ of isotropic projective lines in $\mathbb{P}(V)$, which is of dimension 3. The fibers are isomorphic to the scheme $\text{Hom}_d(C, \mathbb{P}^1)$ of morphisms of degree $d$ from $C$ to $\mathbb{P}^1$ and are of dimension $2d$. The dimension of $J$ is therefore $2d + 3$. If $d \geq 4$, we have $2d + 3 < 3d$ and then $J$ cannot be an irreducible component of $\text{Hom}_d(C,X)$.

Quillen Homology for Operads via Gröbner Bases

Vladimir Dotsenko and Anton Khoroshkin

Received: March 23, 2012
Revised: December 23, 2012
Communicated by Stefan Schwede

Abstract. The main goal of this paper is to present a way to compute Quillen homology of operads. The key idea is to use the notion of a shuffle operad we introduced earlier; this allows to compute, for a symmetric operad, the homology classes and the shape of the differential in its minimal model, although does not give an insight on the symmetric groups action on the homology. Our approach goes in several steps. First, we regard our symmetric operad as a shuffle operad, which allows to compute its Gröbner basis. Next, we define a combinatorial resolution for the “monomial replacement” of each shuffle operad (provided by the Gröbner bases theory). Finally, we explain how to “deform” the differential to handle every operad with a Gröbner basis, and find explicit representatives of Quillen homology classes for a large class of operads. We also present various applications, including a new proof of Hoffbeck’s PBW criterion, a proof of Koszulness for a class of operads coming from commutative algebras, and a homology computation for the operads of Batalin–Vilkovisky algebras and of Rota–Baxter algebras.

INTRODUCTION

CONTEXT AND THE MAIN GOAL OF THE PAPER

Quillen’s philosophy of homotopical algebra [53, 54] suggests to study invariants of associative algebras (and their variants in various monoidal categories) within the homotopical category obtained from the usual category of (differential graded) algebras via the localisation inverting all quasi-isomorphisms. One of the key invariants of that sort is what is now called Quillen homology, the left derived functor of the functor of indecomposables $A \mapsto A^{ab} := A/A^2$ (this functor is also somewhat informally called “abelianisation”). Since we work in the homotopical category, studying an algebra is the same as studying its cofibrant replacement, which in many known model categories (associative algebras, operads etc.) is given by a (quasi-)free resolution. One such resolution, given by the cobar-bar construction, is readily available, however, sometimes it is preferable (and possible) to have a smaller resolution. The so called minimal resolution (if it exists) has Quillen homology of the algebra as its space of generators. In general, given an algebra $A$ and a free resolution $(F_\bullet, d)$ of $A$, Quillen homology $H^Q(A)$ is isomorphic to the homology of the differential induced on the space of indecomposable elements of $F_\bullet$, i.e., on the space of generators of our resolution. As a vector space, it can also be identified with the homology of the differential induced on the space of generators of a resolution of the trivial $A$-module by free right $A$-modules, that is the appropriate Tor groups, also called syzygies of the given algebra. One general way of computing the space of syzygies is a step-by-step procedure which is usually referred to as the Koszul–Tate method [36, 60]. However, in some cases it is possible to visualise the whole space of syzygies “in one go”, like the Koszul duality theory [27, 51] suggests. A question raised by Jean-Louis Loday in [42, Question 7] is to compare the computations via the Koszul duality theory (when available) with those by the Koszul–Tate approach. In this paper, we give a method that brings those two approaches together, applying the machinery of Gröbner bases and thus understanding the intrinsic structure of relations between relations in the spirit of Koszul duality.

One of most important practical results provided (in many different frameworks) by Gröbner bases is that when dealing with various linear algebra information (bases, dimensions etc.) one can replace an algebra with complicated relations by an algebra with monomial relations without losing any information of that sort. When it comes to questions of homological algebra, things become more subtle, since homology may “jump up” for a monomial replacement of an algebra. However, the idea of applying Gröbner bases to problems of homological algebra is far from hopeless. It turns out that for monoids with monomial relations it is often possible to construct very neat resolutions that can be used for various computations; furthermore, the data computed by these resolutions can be used to obtain results in the general...
Proposed methods

Operads that usually arise naturally in various topics are symmetric operads; they encode intrinsic properties of operations with several arguments acting on certain algebraic or geometric objects, and as such are equipped with the action of symmetric groups. The presence of such an action instantly implies that there is no meaningful notion of a monomial operad: any notion of that sort is not rich enough for every operad to have a monomial replacement. A way to deal with this problem proposed in [13] is to include symmetric operads in a larger universe of shuffle operads, where every object has a monomial replacement. On shuffle operads, no symmetries are allowed to act directly: the only way symmetries enter the game is through the formulae for compositions of operations. In that category, it is possible to make the Gr"obner bases machinery work, and hence there is hope that it can be applied to questions of homological algebra. It is indeed possible, along the following lines.

We begin with a resolution which generally not minimal even in the monomial case, but has the advantage of being purely combinatorial and not using much information about the underlying monoidal category. It is based on the inclusion–exclusion principle, and is in a sense a version of the cluster method of enumerative combinatorics due to Goulden and Jackson [26]. The resolution obtained is not always minimal, and we also discuss how to use it to compute the Quillen homology as a vector space, using algebraic Morse theory. This is followed, by an explanation of how to “deform” the differential of our resolution to incorporate lower terms of relations and handle arbitrary algebras with known Gr"obner bases. Note that the Quillen homology of a symmetric operad is, as a homotopy shuffle co-operad, isomorphic to the Quillen homology of that operad considered in the shuffle category. Since our results allow to compute the homotopy co-operad structure on the Quillen homology via the homotopy transfer theorem for homotopy co-operads [17], in principle we recover most of the information on Quillen homology in the symmetric category (and of course the shape the differential in the minimal model). The reader will see that in some of the examples we discuss.

As we mentioned earlier, our approach generalises the Koszul duality theory for defining relations of arbitrary degrees. In the case of a Koszul operad, one is able to write down a formula for its minimal resolution right away: such a resolution has the Koszul dual co-operad as its space of generators. Most known examples of Koszul algebras and operads actually satisfy the PBW condition [31, 51], or equivalently have a quadratic Gr"obner basis [13, 50]. In that case, the minimal resolution provided by the Koszul duality theory coincides with that obtained by our methods. Generally, Gr"obner bases allow to choose a “good” system of relations that captures the structure of relations between relations (higher syzygies).
Related results

In the case of usual associative algebras and right modules, the approach we discuss has been known since the celebrated paper of Anick [1] where for a monomial algebra a minimal right module resolution of the trivial module was computed, and an explicit way to deform the differential was presented to handle the general case. Later, Anick’s resolution was generalised to the case of categories by Malbos [44] who also asked whether this work could be extended to the case of operads. Results of this paper give such an extension, and suggest a way to handle associative algebras presented via generators and relations in many different monoidal categories (e.g. commutative associative algebras, associative dialgebras, (shuffle) coloured operads, dioperads, 4PROP’s) in a uniform way. If, in addition, we assume that our algebras are linear spans of algebras in sets, our constructions are closely related to those of free polygraphic resolutions for (∞, 1)-categories obtained by methods of rewriting theory [49]; this relationship is currently investigated by the first author in a joint work with Yves Guiraud and Philippe Malbos, and will be discussed elsewhere.

Overview of applications

There are various applications of our approach; some of them are presented in this paper. Two interesting theoretical applications are a new short proof of Hoffbeck’s PBW criterion for operads [31], and an upper bound on the homology for operads obtained from commutative algebras; in particular, we prove that an operad obtained from a Koszul commutative algebra is Koszul. Some interesting concrete examples where all steps of our construction can be completed are the case of the operad $RB$ of Rota–Baxter algebras, its noncommutative analogue $ncRB$, and, the last but not the least, the operad $BV$ of Batalin–Vilkovisky algebras. Using our methods, we were able to compute Quillen homology of the operad $BV$ and relate it to the gravity operad of Getzler [25]. After completing the first version of this paper in 2009 [12], we learned that these (and other) results concerning the operad $BV$ were also obtained independently by Drummond-Cole and Vallette [17]. Our methods appear to be completely different; we also believe that our approach to the operad $BV$ is of independent interest as an illustration of a rather general method to compute Quillen homology. It also shows how to use information coming “from the symmetric world” to partly understand the shape of trees that appear in the formula for the differential of the minimal model. This idea (to move to the universe of shuffle operads, compute the vector space structure there, and then to use known information on our operad to obtain results about the symmetries of homology) also belongs to the core of the shuffle operad approach.
Plan of the paper

This paper is organised as follows. 
In Section 1, we recall necessary background information on shuffle operads, and provide references for definitions and results that are relevant for the paper but are not discussed in detail. 
In Section 2, we present an “inclusion-exclusion” resolution for an arbitrary shuffle operad with monomial relations, which we then use in the subsequent sections. 
In Section 3, we use algebraic Morse theory to construct representatives for Quillen homology classes under a minor assumption on the combinatorics of defining relations. This section includes brief recollections of algebraic Morse theory, as well as full proofs of existence of Morse matchings; whereas results of that section are important for some of our examples, a reader primarily interested in applications may skip the proofs without any disadvantages for understanding the rest of the paper. 
In Section 4, we use a version of homological perturbation to obtain a resolution for a general shuffle operad with a Gröbner basis. 
In Section 5, we exhibit applications of our results outlined above. Those are a new proof of the PBW criterion, homology estimates for operads coming from commutative algebras, and a computation of Quillen homology for the operads $RB$, $ncRB$, and $BV$. 

Acknowledgments

Work on this paper ended up being spread over several years, and we benefited a lot from discussing preliminary versions of this paper with our colleagues. We thank Frédéric Chapoton, Yves Guiraud, Eric Hoffbeck, Muriel Livernet, Jean–Louis Loday, Philippe Malbos and Dmitri Piontkovski for useful discussions, remarks and references to literature. Special thanks are due to Li Guo for drawing our attention to Rota–Baxter algebras as an example to which our methods could be applied, and especially to Bruno Vallette for many stimulating discussions and in particular for explaining the approach to the operad $BV$ used in his joint work with Gabriel Drummond-Cole. The first author gratefully acknowledges the hospitality of the University Lyon 1 during the final stage of working on this paper. The second author wishes to thank Dublin Institute for Advanced Studies and the University of Luxembourg, where parts of this paper were completed, for invitations to visit and excellent working conditions. 

1 Recollections

All vector spaces and (co)chain complexes throughout this work are defined over an arbitrary field $k$. To handle suspensions, we introduce a formal symbol $s$ of degree 1, and define, for a graded vector space $V$, its suspension $sV$. 
Vladimir Dotsenko and Anton Khoroshkin

as \( k \Sigma \otimes V \). All algebras and operads are assumed non-unital; to adapt our results for unital algebras, one has to restrict the setup to augmented algebras, and consider the abelianisation \( A^\phi = A_+/A_+^2 \), where \( A_+ \) is the augmentation ideal.

The main thing about shuffle operads that is crucial for our constructions is the relevant combinatorics of trees. Hence, in this section we pay most attention in explaining that combinatorics in detail. We also discuss the precise relationship between homological/homotopical results obtained in the symmetric and in the shuffle category, since most of the applications we have in mind concern symmetric operads. For information on operads in general, we refer the reader to the book [40], for information on shuffle operads and Gröbner bases for operads in not necessarily quadratic case — to our paper [13]. Throughout this paper by an operad, unless otherwise specified, we mean a shuffle operad: there is no machinery of Gröbner bases available in the symmetric case, so we have to sacrifice the symmetric groups action. Of course, in some cases we deal with non-symmetric operads, and in that case there is nothing to sacrifice, and in fact the story is somewhat richer since one can include constants (operations of arity 0) in the picture and avail of Gröbner bases at no additional cost. For details on that, see [16]. For the sake of brevity, in this paper we shall discuss shuffle operads in detail, while non-symmetric operads will only appear in some examples.

1.1 Shuffle operads, bar construction and homology

Let us denote by \( \text{Ord} \) the category whose objects are non-empty finite ordered sets (with order-preserving bijections as morphisms). Also, we denote by \( \text{Vect} \) the category of vector spaces (with linear operators as morphisms). It is usually enough to assume vector spaces to be finite-dimensional, though sometimes more generality is needed, and one assumes, for instance, that they are graded with finite-dimensional homogeneous components.

**Definition 1.1.** A (non-symmetric) collection is a contravariant functor from the category \( \text{Ord} \) to the category \( \text{Vect} \). Because of functoriality, a nonsymmetric collection \( \mathcal{P} \) is completely determined by its components \( \mathcal{P}(n) := \mathcal{P}([1, \ldots, n]), \ n \geq 1 \).

For two nonsymmetric collections \( \mathcal{P} \) and \( \mathcal{D} \), the shuffle composition product of \( \mathcal{P} \) and \( \mathcal{D} \) is the non-symmetric collection \( \mathcal{P} \circ_{sh} \mathcal{D} \) defined by the formula

\[
(\mathcal{P} \circ_{sh} \mathcal{D})(l) := \bigoplus_{k \geq 1} \mathcal{P}(k) \otimes \left( \bigoplus_{\phi: [1] \rightarrow [k]} \mathcal{D}(\phi^{-1}(1)) \otimes \cdots \otimes \mathcal{D}(\phi^{-1}(k)) \right),
\]

where the sum is taken over all shuffling surjections \( f \), that is surjections for which \( \min \phi^{-1}(i) < \min \phi^{-1}(j) \) whenever \( i < j \).

**Proposition 1.2** ([13]). The shuffle composition product equips the category of non-symmetric collections with a structure of a monoidal category.
Definition 1.3. A **shuffle operad** is a monoid in the category of non-symmetric collections equipped with the shuffle composition product.

For the monoidal category of shuffle operads, it is possible to define the bar complex of an operad $O$. The bar complex $B^\ast(O)$ is a dg co-operad freely generated by the suspension $sO$; the differential comes from operadic compositions in $O$. Similarly, for a co-operad $Q$, it is possible to define the cobar complex $\Omega^\ast(Q)$, which is a dg operad freely generated by $s^{-1}Q$, with the appropriate differential. The bar-cobar construction $\Omega^\ast(B^\ast(O))$ gives a free resolution of $O$. This can be proved in a rather standard way, similarly to known proofs in the case of operads, properads etc. \[21, 27, 62\]. The general homotopical algebra philosophy mentioned in the introduction is applicable in the case of operads as well; various checks and justifications needed to ensure that are quite standard and similar to the ones available in the literature; we refer the reader to \[6, 22, 30, 47, 55, 59\] where symmetric operads are handled. Thus, the Quillen homology of an operad can be computed as homology of its bar complex (since the abelianisation of the bar-cobar construction is the bar complex), though sometimes this complex is too big to handle, so it is important to seek more economic free resolutions. Our approach allows to build free resolutions for shuffle operads with known Gröbner bases, thus giving an alternative way to compute Quillen homology.

1.2 Symmetric vs shuffle

Let us explain precisely what information on Quillen homology for symmetric operads “survives” in the shuffle world, and what is lost. Of course, the information on the symmetric group actions does get lost. However, we argue that all other relevant structures on the homology do survive. Recall that the forgetful functor $\mathcal{P} \rightarrow \mathcal{P}'$ from the category of symmetric collections to the category of nonsymmetric collections (with the shuffle product) is monoidal \[13, Prop. 3\]. This easily implies the following

**Proposition 1.4.** For a symmetric operad $\mathcal{P}$, we have

$$B^\ast(\mathcal{P}') \cong B^\ast(\mathcal{P}),$$

that is the (symmetric) bar complex of $\mathcal{P}$ is isomorphic, as a shuffle dg co-operad, to the (shuffle) bar complex of $\mathcal{P}'$.

Appropriate homotopy transfer for homotopy co-operads \[17\] (together with the observation that homotopy co-operad maps on the Quillen homology are up to suspension equal to components of the differential in the minimal model) implies

**Corollary 1.5.** For a symmetric operad $\mathcal{P}$, we have

$$H^Q(\mathcal{P}') \cong H^Q(\mathcal{P}),$$
that is the (symmetric) Quillen homology $P$ is isomorphic, as a shuffle homotopy co-operad, to the (shuffle) Quillen homology of $P^f$. Also, if $\mathcal{R}_P$ denotes the minimal model of an operad $\mathcal{O}$ in the appropriate category (symmetric or shuffle), we have

$$(\mathcal{R}_P)^f \cong \mathcal{R}_{P^f}$$

as shuffle dg operads.

In particular, this means that on the minimal model in the shuffle category it is in principle possible to introduce a symmetric groups action compatible with the differential so that it becomes precisely the minimal model in the symmetric category.

1.3 Tree monomials

Let us recall tree combinatorics used to describe monomials in shuffle operads. See [13] for more details.

Basis elements of the free operad are represented by (decorated) trees. A (rooted) tree is a non-empty connected directed graph $T$ of genus 0 for which each vertex has at least one incoming edge and exactly one outgoing edge. Some edges of a tree might be bounded by a vertex at one end only. Such edges are called external. Each tree should have exactly one outgoing external edge, its output. The endpoint of this edge which is a vertex of our tree is called the root of the tree. The endpoints of incoming external edges which are not vertices of our tree are called leaves.

Each tree with $n$ leaves should be (bijectively) labelled by the standard $n$-element set $[n] = \{1, 2, \ldots, n\}$. For each vertex $v$ of a tree, the edges going in and out of $v$ will be referred to as inputs and outputs at $v$. A tree with a single vertex is called a corolla. There is also a tree with a single input and no vertices called the degenerate tree. Trees are originally considered as abstract graphs but to work with them we would need some particular representatives. For a tree with labelled leaves, its canonical planar representative is defined as follows. In general, an embedding of a (rooted) tree in the plane is determined by an ordering of inputs for each vertex. To compare two inputs of a vertex $v$, we find the minimal leaves that one can reach from $v$ via the corresponding input. The input for which the minimal leaf is smaller is considered to be less than the other one.

Let us introduce an explicit realisation of the free operad generated by a collection $\mathcal{M}$. The basis of this operad will be indexed by canonical planar representatives of trees with decorations of all vertices. First of all, the simplest possible tree is the degenerate tree; it corresponds to the unit of our operad. The second simplest type of trees is given by corollas. We shall fix a basis of $\mathcal{M}$ and decorate the vertex of each corolla with a basis element; for a corolla with $n$ inputs, the corresponding element should belong to the basis of $\mathcal{Y}(n)$. The basis for whole free operad consists of all canonical planar representatives of trees built from these corollas (explicitly, one starts with this collection of
corollas, defines compositions of trees in terms of grafting, and then considers all trees obtained from corollas by iterated shuffle compositions). We shall refer to elements of this basis as tree monomials. Vice versa, if we forget the labels of vertices and leaves of a tree monomial $\alpha \in \mathcal{F}_M$, we obtain a planar tree. We shall refer to this planar tree as the underlying tree of $\alpha$.

For example, if $O = \mathcal{F}_M$ is the free operad for which the component $\mathcal{M}(n)$ is only non-zero for $n = 2$, and $\mathcal{M}(2) = k\langle \circ \rangle$, the basis of $\mathcal{F}_M(3)$ is given by the tree monomials

\[
\begin{array}{c}
\circ \\
\circ \\
\circ
\end{array}
\quad,
\begin{array}{c}
\circ \\
\circ \\
\circ
\end{array}
\quad,
\begin{array}{c}
\circ \\
\circ \\
\circ
\end{array}
\quad,
\begin{array}{c}
\circ \\
\circ \\
\circ
\end{array}
\quad.
\]

There are two standard ways to think of elements of an operad defined by generators and relations: using either tree monomials or operations. For example, the above tree monomials correspond to operations

\[
(a_1 \circ a_2) \circ a_3, \quad (a_1 \circ a_3) \circ a_2, \quad \text{and} \quad a_1 \circ (a_2 \circ a_3).
\]

Our approach is somewhere in the middle between the two viewpoints: we strongly encourage the reader to think of tree monomials, but to write down the formulas required for definitions and proofs we prefer the language of operations since it makes things more compact.

Example 1.6. The following is a tree monomial in the free operad $\mathcal{F}_M$ generated by some collection $\mathcal{M}$ with $\circ, \bullet \in \mathcal{M}(2)$:

\[
\begin{array}{c}
1 \\
3 \\
2 \\
7 \\
4 \\
6
\end{array}
\quad.
\]

In the language of operations, it corresponds to the operation

\[
((a_1 \circ a_3) \bullet a_5) \circ ((a_2 \bullet a_7) \circ (a_4 \circ a_6)).
\]

Divisors of a tree monomial $\alpha$ in the free operad correspond to a special kind of subgraphs of its underlying tree. Allowed subgraphs contain, together with each vertex, all its incoming and outgoing edges (but not necessarily other endpoints of these edges). Throughout this paper we consider only this kind of subgraphs, and we refer to them as subtrees hoping that it does not lead to any confusion. Clearly, a subtree $T'$ of every tree $T$ is a tree itself. Let us define the tree monomial $\alpha'$ corresponding to $T'$. To label vertices of $T'$, we recall the labels of its vertices in $\alpha$. We immediately observe that these labels match the restriction labels of a tree monomial should have: each vertex has the same number of inputs as it had in the original tree, so for a vertex with $n$ inputs its label does belong to the basis of $\mathcal{M}(n)$. To label leaves of $T'$, note that each such leaf is either a leaf of $T$, or is an output of some vertex of $T$. This
allows us to assign to each leaf \( l' \) of \( T' \) a leaf \( l \) of \( T \), which we call the smallest descendant of \( l' \): if \( l' \) is a leaf of \( T \), put \( l = l' \), otherwise let \( l \) be the smallest leaf of \( T \) that can be reached through \( l' \). We then number the leaves according to their smallest descendants: the leaf with the smallest possible descendant gets the label 1, the second smallest — the label 2 etc.

**Example 1.7.** Let us consider the following two choices of subtrees of the tree from Example 1.6:

\[
\begin{array}{c}
1 & 3 & 2 & 7 & 4 & 6 \\
\text{and} \\
1 & 5 & 2 & 4
\end{array}
\]

In the first case, the subtree marked by bold lines yields the tree monomial \( \begin{array}{c}
1 & 4 & 2 & 3 \\
\end{array} \), and the ”standardisation” re-labelling, as above, gives the tree monomial \( \begin{array}{c}
2 & 7 & 4 & 6 \\
\end{array} \). In the second case, the subtree marked by bold lines yields the tree monomial \( \begin{array}{c}
1 & 4 & 2 & 3 \\
\end{array} \), and the ”standardisation” re-labelling gives the same tree monomial \( \begin{array}{c}
2 & 7 & 4 & 6 \\
\end{array} \). In the language of operations,

\[
(a_1 \bullet a_3) \circ (a_2 \circ a_4) \approx (a_2 \bullet a_7) \circ (a_4 \circ a_6) \approx (a_1 \bullet a_4) \circ (a_2 \circ a_3).
\]

Thus, \( \begin{array}{c}
1 & 4 & 2 & 3 \\
\end{array} \) occurs as a divisor of the original tree monomial at two different places.

For two tree monomials \( \alpha, \beta \) in the free operad \( \mathcal{T}_{\mathcal{M}} \), we say that \( \alpha \) is divisible by \( \beta \), if there exists a subtree of the underlying tree of \( \alpha \) for which the corresponding tree monomial \( \alpha' \) is equal to \( \beta \).

There exist several ways to introduce a total ordering of tree monomials in such a way that the operadic compositions are compatible with that total ordering. A Gröbner basis of an ideal \( I \) of the free operad is a system \( S \) of generators of \( I \) for which the leading monomial of every element of the ideal is divisible by one of the leading terms of elements of \( S \). Such a system of generators allows to perform “long division” modulo \( I \), computing for every element
its canonical representative. There exists an algorithmic way to compute a Grobner basis starting from any given system of generators (“Buchberger’s algorithm for shuffle operads”). For our purposes, it is important to note that if the tree monomials of our operad have additional internal grading, and the relations are homogeneous with respect to that grading, then the corresponding reduced Grobner basis is also homogeneous, as well as all our homological constructions.

1.4 Operads in the Differential Graded Setting

The above description of the free shuffle operad works almost literally when we work with operads whose components are chain complexes (as opposed to vector spaces), and the symmetric monoidal structure on the corresponding category involves signs. The only difference is that every tree monomial should carry an ordering of its internal vertices, so that two different orderings contribute appropriate signs. In this section, we give an example of a shuffle dg operad that should help a reader to understand the graded case better; this operad was introduced and explored in [48].

Definition 1.8. The odd \((2k+1)\)-associative operad is a non-symmetric operad with one generator \(μ\) of arity \(2k+1\) and odd homological degree, and relations

\[ μ \circ p \, μ = μ \circ_{2k+1} μ \quad \text{for all } p \leq 2k. \]

Let us show that the Buchberger algorithm for operads from [13] discovers a cubic relation in the Grobner basis for this operad, thus showing that this operad fails to be PBW in the sense of Hoffbeck [31] (for this particular ordering). We use the path-lexicographic ordering of monomials.

From the common multiple \((μ \circ_1 μ) \circ_1 μ\) of the leading term \(μ \circ_1 μ\) with itself, we compute the S-polynomial

\[ (μ \circ_{2k+1} μ) \circ_1 μ - μ \circ_1 (μ \circ_{2k+1} μ). \]

We can perform the following chain of reductions (with leading monomials underlined):

\[
\begin{align*}
& (μ \circ_{2k+1} μ) \circ_1 μ - μ \circ_1 (μ \circ_{2k+1} μ) = (μ \circ_{2k+1} μ) \circ_1 μ - (μ \circ_1 μ) \circ_{2k+1} μ \mapsto
& \mapsto (μ \circ_{2k+1} μ) \circ_1 μ - (μ \circ_{2k+1} μ) \circ_{2k+1} μ = -(μ \circ_1 μ) \circ_{4k+1} μ - (μ \circ_{2k+1} μ) \circ_{2k+1} μ \mapsto
& \mapsto -(μ \circ_{2k+1} μ) \circ_{4k+1} μ - (μ \circ_{2k+1} μ) \circ_{2k+1} μ = -(μ \circ_{2k+1} μ) \circ_{4k+1} μ - μ \circ_{2k+1} (μ \circ_1 μ) \mapsto
& \mapsto -(μ \circ_{2k+1} μ) \circ_{4k+1} μ - μ \circ_{2k+1} (μ \circ_{2k+1} μ) = -2(μ \circ_{2k+1} μ) \circ_{4k+1} μ.
\end{align*}
\]

Note that we used the formula \((μ \circ_{2k+1} μ) \circ_1 μ = -(μ \circ_1 μ) \circ_{4k+1} μ\) which reflects the fact that the operation \(μ\) is of odd homological degree.

The monomial \((μ \circ_{2k+1} μ) \circ_{4k+1} μ\) cannot be reduced further, and we recover the relation \((μ \circ_{2k+1} μ) \circ_{4k+1} μ = 0\) discovered in [48]. Furthermore, we arrive at the following proposition (note the similarity with the computation of the Grobner basis for the operad AntiCom in [13]).
Proposition 1.9. Elements \(\mu \circ_p \mu - \mu \circ_{2k+1} \mu\) with \(1 \leq p \leq 2k\) and \((\mu \circ_{2k+1} \mu) \circ_{4k+1} \mu\) form a Gröbner basis for the operad of odd \((2k+1)\)-associative algebras.

2 Resolution for monomial relations

Assume that the operad \(O = \mathcal{F}_\mathcal{M}/(\mathcal{G})\) is generated by a collection of finite sets \(\mathcal{M} = \{\mathcal{M}(n)\}\), and that \(\mathcal{G}\) consists of tree monomials, so we are dealing with an operad that only has monomial relations. We shall explain how to construct a free resolution of \(O\).

Our first step is to construct a free shuffle dg operad \(A\) which does not take the account relations of \(O\); it is a somewhat universal object for operads generated by \(\mathcal{M}\), various suboperads of \(A\) will be used as resolutions for various choices of \(\mathcal{G}\).

2.1 The inclusion–exclusion operad

Let \(T\) be a tree monomial, and let the symbols \(S_1, \ldots, S_q\) be in one-to-one correspondence with all the divisors of \(T\). We denote by \(\mathcal{A}(T)\) the vector space \(\mathbb{k}T \otimes \Lambda(S_1, \ldots, S_q)\). We shall say that underlying tree monomial for elements of this vector space is \(T\). The degree \(-1\) derivations \(\partial_i\) on the exterior algebra defined by the rule \(\partial_i(S_j) = \delta_{ij}\) anticommute, and the differential \(d = \sum_{i=1}^q \partial_i\) makes \(\mathcal{A}(T)\) into a chain complex isomorphic to the augmented chain complex of a \((q-1)\)-dimensional simplex \(\Delta^{q-1}\).

By definition, the chain complex \(\mathcal{A}(n)\) is the direct sum of complexes \(\mathcal{A}(T)\) over all tree monomials \(T\) with \(n\) leaves. There is a natural operad structure on the collection \(\mathcal{A} = \{\mathcal{A}(n)\}\); the operadic composition composes the trees, and computes the wedge product of symbols labelling their divisors. Overall, we defined a shuffle dg operad, which we shall call the inclusion–exclusion operad.

Let us emphasize that the symbols \(S_i\) correspond to divisors, i.e. mark occurrences of tree monomials in \(T\) rather than monomials themselves, so in particular the Koszul sign rule does not imply that a composition of an element of our operad with itself is equal to zero. Basically, when computing products, the \(S\)-symbols “remember” which divisors of factors they come from. Graphically, it is convenient to think of basis elements of our chain complex as tree monomials with some of the occurrences of relations additionally marked, as in Example 1.7.

The following example should make our construction more clear.

Example 2.1. Assume that the operad \(O\) has two binary generators \(\circ\) and \(\cdot\).
Then the corresponding operad \( \mathcal{A} \) contains, among others, two elements
\[
\begin{array}{c}
\begin{array}{ccccc}
2 & 5 & 3 & 4 & \\
1 & & & & \\
\end{array}
\end{array}
\quad\text{and}\quad
\begin{array}{c}
\begin{array}{ccccc}
1 & 3 & 2 & \\
& & & & \\
\end{array}
\end{array}
\]

An appropriate shuffle composition of these two produces the element
\[
\begin{array}{c}
\begin{array}{ccccccc}
1 & 2 & 3 & 4 & 6 & \\
& 5 & & & & \\
\end{array}
\end{array}
\]

where two different divisors are marked. Incidentally, the underlying tree monomial for each of them is
\[
\begin{array}{c}
\begin{array}{ccccc}
1 & 3 & 2 & \\
& & & & \\
\end{array}
\end{array}
\].

Let us call the first tree \( T \), the second tree \( T' \), the first divisor \( S \), and the second divisor \( S' \). On the level of formulas, we have
\[
(T \otimes S) \circ \phi (T' \otimes S') = (T \circ \phi T') \otimes S_1 \wedge S_2,
\]
where \( \phi: [1,2,3,4,5,6,7] \to [1,2,3,4,5] \) is the shuffle surjection with \( \phi(1) = \phi(3) = \phi(5) = 1, \phi(2) = 2, \phi(4) = 3, \phi(6) = 4, \phi(7) = 5 \), and \( S_1 \) and \( S_2 \) indicate the two different divisors of \( T \circ \phi T' \) equal to
\[
\begin{array}{c}
\begin{array}{ccccc}
1 & 3 & 2 & \\
& & & & \\
\end{array}
\end{array}
\].

Note that even though the underlying tree monomials of the two divisors coincide, the wedge product is not equal to zero, since the letters \( S \) correspond to distinct divisors, that is occurrences of tree monomials, not tree monomials themselves.

In fact, the underlying operad of the dg operad \( \mathcal{A} \) is free. Indeed, let us call a \( \text{“monomial”} \) \( T \otimes S_{i_1} \wedge \cdots \wedge S_{i_q}, q \geq 0, \) indecomposable, if it is not a composition in the operad \( \mathcal{A}/q \) of two monomials of the same type. (This means that each edge between the two internal vertices of \( T \) is an edge between two internal vertices of at least one of the divisors \( S_{i_1}, \ldots, S_{i_q} \); note that some of the internal vertices of \( T \) are leaves of its divisors, and hence are not considered internal vertices of the respective divisors.) It is easy to see that \( \mathcal{A} \) is freely generated by indecomposable elements; those are elements \( m \otimes 1 \) with \( m \in \mathcal{M} \) being a generator of \( \mathcal{O} \), and indecomposable monomials \( T \otimes S_{i_1} \wedge \cdots \wedge S_{i_q}, q \geq 1 \).

For each monomial \( T \otimes S_{i_1} \wedge \cdots \wedge S_{i_q} \) different from the generators described above, and each internal edge of \( T \) that is not an internal edge of either of \( S_{i_1}, \ldots, S_{i_q} \), the endpoint of that edge which is further from the root of \( T \) is a "grafting point": the subtree growing from this vertex (and its divisors among \( S_{i_1} \)) factors out in our operad. This factorisation procedure gives a unique way to factorise elements as compositions of generators.
So far we did not use the relations of our operad. Let us incorporate relations in the picture.

### 2.2 Suboperads of the inclusion–exclusion operad

Let $\mathcal{G}$ be the set of relations of our operad $\mathcal{O}$. The dg operad $(\mathcal{A}_G, d)$ is defined similarly to $\mathcal{A}$, but with the additional restriction that every symbol $S_k$ corresponds to a divisor of $T$ for which the underlying tree monomial is a relation. The differential $d$ is the restriction of the differential defined above. Informally, an element of the operad $\mathcal{A}_G$ is a tree with some distinguished divisors that are relations from the given set.

**Theorem 2.2.** The dg operad $(\mathcal{A}_G, d)$ is a free resolution (as a shuffle operad) of the corresponding operad with monomial relations $\mathcal{O} = \mathcal{F}_G/(\mathcal{G})$.

**Proof.** Similarly to the case of the operad $\mathcal{A}$, the operad $\mathcal{A}_G$ is freely generated by its elements $m \otimes 1$ with $m \in \mathcal{M}$ and all indecomposable monomials $T \otimes S_1 \wedge \cdots \wedge S_q, q \geq 1$, where each of the divisors $S_i$ is a relation of $\mathcal{O}$.

Let us prove that $\mathcal{A}_G$ provides a resolution for $\mathcal{O}$. Since the differential $d$ only omits wedge factors but does not change the tree monomial, the chain complex $\mathcal{A}_G$ is isomorphic to the direct sum of chain complexes $\mathcal{A}_T$ spanned by the elements for which the first tensor factor is the given tree monomial $T$. If $T$ is not divisible by any relation, the complex $\mathcal{A}_T$ is concentrated in degree 0 and is spanned by $T \otimes 1$. Thus, to prove the theorem, we should show that $\mathcal{A}_T$ is acyclic whenever $T \otimes 1$ is divisible by some relation $g_i$.

Assume that there are exactly $k$ divisors of $T$ which are relations of $\mathcal{O}$. We immediately see that the complex $\mathcal{A}_T$ is isomorphic to the chain complex of a simplex $\Delta_{k-1}$ which is acyclic whenever $k > 0$. □

**Remark 2.3.** Using the machinery of twisting cochains [7], one can obtain from the free dg operad resolution a resolution of the trivial module by free right modules whose spaces of generators of various homological degrees are the same as the spaces of generators of the original operad resolution. More precisely, the differential of every generator in our free operad resolution is a sum of compositions of generators; this provides the space of generators with a structure of a homotopy co-operad, and the twisting cochain method applies. See [39, 52] for details in the (simpler) case of associative algebras, and [17] for details in the operad case.

### 3 Homology classes for monomial operads

In general, the fact that “trees grow in several different directions”, means that it is more difficult to describe representatives of homology classes combinatorially in the same way as it can be done for the case of associative algebras [1]. However, in some cases it is possible to come up with a reasonable description.
In this section, we shall describe homology classes under a minor restriction on the combinatorics of defining relations.

3.1 Algebraic Morse theory: recollections

To obtain our description, we use the algebraic Morse theory developed independently in [32, 37, 58]. We refer the reader to those references for details; for our purposes, the algebraic Morse theory is a way to describe a smaller subcomplex of a chain complex having the same homology. It is done as follows. Suppose that our chain complex \((C_\bullet, d)\) has a basis \(X = \bigsqcup_{i \geq 1} X_i\), where \(X_i\) is the basis of the space \(C_i\) of our complex; this basis should be finite or satisfy some local finiteness condition (i.e., internal grading). We consider a directed graph \(\Gamma\) whose vertex set \(V\) coincides with \(X\), and the edge set \(E\) reflects the combinatorics of the differential: there is an edge from \(x \in X_i\) to \(y \in X_{i-1}\) if \(y\) appears in \(d(x)\) with a non-zero coefficient. A set of edges \(M \subset E\) is called a Morse matching if two conditions are satisfied:

1. every vertex of \(\Gamma\) belongs to at most one edge from \(M\);
2. the graph \(\Gamma'\) on the vertex set \(V\) whose edge set is the union of \(E \setminus M\) with the set of all edges of \(M\) reversed has no directed cycles.

The vertices that do not belong to any edge of \(M\) are called critical. The subset of critical vertices of \(X_i\) is denoted by \(X_i^M\). The key result of algebraic discrete Morse theory states that there is a way to define a new differential \(d^M\) on the linear span \(C^M_\bullet\) of critical vertices so that the chain complex \((C^M_\bullet, d^M)\) is quasi-isomorphic to \((C_\bullet, d)\). The only property of this differential that we shall really need is that its “structure constants”, that is the coefficients \([v : v']\) in the formula

\[
d^M(v) = \sum_{v'} [v : v']v'
\]

are defined as sums over paths from \(v\) to \(v'\) in the graph \(\Gamma'\).

3.2 Homology classes via algebraic Morse theory

Let \(O = \mathcal{F}_M / (\mathcal{G})\) be an operad generated by the collection \(M\) with monomial relations. Quillen homology \(H^Q(\mathcal{G})\) is isomorphic to the homology of the differential induced on the space of indecomposable elements \((\mathcal{A}_d)^{\mathit{adm}}\) of the operad \(\mathcal{A}_d\). That space of generators, as a chain complex, can be decomposed into a direct sum of chain complexes \((\mathcal{A}_d)^{\mathit{adm}}\) spanned by the elements for which the underlying tree monomial is the given tree monomial \(T\), and therefore the Quillen homology acquires a direct sum decomposition

\[
H^Q(\mathcal{G}) = \bigoplus_{T \text{ a tree monomial}} H^Q_\mathcal{T}(\mathcal{G}).
\]
We shall define Morse matchings of chain complexes \((A_G^ab)_{T^b}\) under some technical conditions which we believe to be not very restrictive; at least in all naturally arising examples that we discuss throughout the paper these conditions are fulfilled.

**Definition 3.1.** For a tree monomial \(T\), we call a numbering of the set of all divisors of \(T\) that are relations of \(O\) an Anick numbering if whenever \(i < j < k\) and \(S_i \cap S_j \neq \emptyset\) we have \(S_i \cap S_k \subset S_j \cap S_k\). (Here and below by intersection we mean the most naive combinatorial intersection of divisors inside \(T\).)

Let us give two examples of Anick numberings. The first one, which we shall use as a toy model in this section, explains the term we chose: we shall see that in the case of associative algebras it corresponds to the numbering of divisors used by Anick [1].

**Example 3.2.** Suppose that our operad \(O\) with monomial relations is generated by unary operations. In this case, it is nothing but an associative algebra with monomial relations. If we number subwords of the given word which are relations according to the position of the first letter, the corresponding ordering is manifestly an Anick ordering.

The second example is new, and has a genuine operadic meaning to it; we shall discuss an application of this result in Section 5.2.

We assume that our operad is generated by elements of arity 2. Let us use the usual terms “left combs” and “right combs” for tree monomials corresponding to the operations of the form

\[
a_1(a_2(\ldots (a_k(1, i_2), i_3), \ldots, i_k), i_{k+1}) \quad \text{and} \quad a_1(1, a_2(2, \ldots a_k(1, k, k + 1) \ldots))
\]

respectively: left combs are obtained from the generators by iterated compositions in the first slot, and right combs are obtained from the generators by iterated compositions in the last slot.

**Proposition 3.3.** Suppose that \(O = \mathcal{F}_M/\langle \mathcal{G} \rangle\) is an operad with binary generators and monomial relations, \(\mathcal{G} = \mathcal{G}_l \cup \mathcal{G}_r\), where \(\mathcal{G}_l\) consists of left combs and \(\mathcal{G}_r\) consists of right combs, and at least one of the sets \(\mathcal{G}_l, \mathcal{G}_r\) is contained in \(\mathcal{F}_M(3)\). Then for each tree monomial \(T\), the set of all divisors of \(T\) that are relations admits an Anick numbering.

**Proof.** Without loss of generality, \(\mathcal{G}_l \subset \mathcal{F}_M(3)\). Let us define a partial ordering of the set of all divisors of \(T\) that are relations of \(O\) as follows: \(S < S'\) if the root of \(S'\) is on the path from the root of \(T\) to the root of \(S\), or if \(S = S'\) share the same root, \(S\) is a left comb and \(S'\) is a right comb. Let us prove that if we extend this partial ordering to a total ordering in any way, and consider the numbering of the divisors according to that total ordering in the increasing order, the numbering thus obtained is an Anick numbering. Indeed, suppose that \(i < j < k\) and \(S_i \cap S_j \neq \emptyset\). There are three different situations when this can happen:
- $S_i$ and $S_j$ are left combs, and the root of $S_j$ is on the path from the root of $T$ to the root of $S_i$.

- $S_i$ and $S_j$ are right combs, and the root of $S_j$ is on the path from the root of $T$ to the root of $S_i$.

- $S_i$ is a left comb, $S_j$ is a right comb, and they share a vertex which is a root vertex of $S_i$.

The only situation when the Anick numbering condition $S_i \cap S_k \subset S_j \cap S_k$ may fail is when $S_i \cap S_k \neq \emptyset$.

In the first case, if $S_k$ is a left comb as well, the condition is manifestly fulfilled. Otherwise, if $S_k$ is a right comb, its intersection with $S_i$ consists of exactly one vertex. If that vertex is the root of $S_j$, then it is contained in $S_j$, and the condition is fulfilled. If it is not the root of $S_j$, it has to be the root of $S_k$, so the root of $S_j$ is manifestly on the path from the root of $T$ to the root of $S_k$, so $S_k \prec S_j$, a contradiction.

In the second case, if $S_k$ is a right comb as well, the condition is manifestly fulfilled. Otherwise, if $S_k$ is a left comb, its intersection with $S_i$ consists of exactly one vertex. If that vertex is the root of $S_j$, then it is contained in $S_j$, and the condition is fulfilled. If it is not the root of $S_j$, it has to be the root of $S_k$, so $S_k \prec S_j$, a contradiction.

In the third case, if $S_k$ is a right comb, then since $S_i \cap S_k \neq \emptyset$, we instantly conclude that $S_k \prec S_j$, a contradiction. If $S_k$ is a left comb, then its intersection with $S_i$ may only consist of one vertex, which is precisely the root vertex of $S_j$, that is the intersection of $S_i$ and $S_j$. $\square$

Throughout this section, we always assume that we are dealing with monomial relations for which for each $T$ the set of its divisors that are relations admits an Anick numbering. Under this assumption, we shall prove the following result.

**Theorem 3.4.** A basis of $H^Q_T(O)$ is in one-to-one correspondence with basis elements $v \in (\mathcal{A}_Q)^{ab}_T$ for which the following two properties hold:

1. For each $S_j$ present in $v$, we have $\partial_j(v) = 0$ in $(\mathcal{A}_Q)^{ab}_T$; in other words, after removing $S_j$, $v$ becomes decomposable,

2. For each $S_j$ not present in $v$, there exists $i < j$ for which $\partial_i(v \wedge S_j) \neq 0$ in $(\mathcal{A}_Q)^{ab}_T$; in other words, after marking $S_j$ in $v$ it is possible to remove the mark from the divisor $S_i$ for some $i < j$ so that the result is indecomposable.

**Proof.** Let us denote by $X$ the natural basis of the chain complex $(\mathcal{A}_Q)^{ab}_T$. It gives rise to a graph $\Gamma$ reflecting the combinatorics of the differential. We shall now describe inductively a matching of the vertices of $\Gamma$, and demonstrate that under our assumptions it is a Morse matching. Let us put $M_1$ to be the set of
edges \( v \rightarrow w \), where \( v, w \in X \), \( w = \pm \partial_j(v) \). For \( k > 1 \) we denote by \( X^{(k-1)} \) the set of critical vertices with respect to the matching \( M_1 \cup \ldots \cup M_{k-1} \), and let

\[
M_k = \{ v \rightarrow w : v, w \in X^{(k-1)}, w = \pm \partial_k(v) \}.
\]

The following proposition is a “bounded version” of Theorem 3.4.

**Proposition 3.5.** The set \( X^{(k)} \) consists of the basis elements \( v \in (\mathcal{A}_q)^{ab} \) for which the following two properties hold:

1. \( (I_k) \) for each \( j \leq k \) such that \( S_j \) is present in \( v \), the monomial \( \partial_j(v) \) is decomposable,
2. \( (II_k) \) for each \( j \leq k \) such that \( S_j \) is not present in \( v \), there exists \( i < j \) for which \( \partial_i(v \wedge S_j) \neq 0 \) in \( (\mathcal{A}_q)^{ab} \).

**Proof.** We prove this statement by induction on \( k \). For \( k = 1 \), it is obvious. Let us explain the step of induction. Let \( v \in X^{(k)} \). By induction, Conditions \( (I_{k-1}) \) and \( (II_{k-1}) \) hold for \( v \).

Let us examine Condition \( (I_k) \) for a basis element \( v \), and for \( j = k \). Assume that it does not hold, so that \( \partial_k(v) \neq 0 \) in \( (\mathcal{A}_q)^{ab} \). We shall now prove that in this case the elements \( v \) and \( \pm \partial_k v \) will have been matched when forming the matching \( M_k \). Basically, it follows from

**Lemma 3.6.** Suppose that \( v \in X^{(k-1)} \), and that \( \partial_k(v) \) is indecomposable. Then \( \pm \partial_k v \) belongs to the set of critical vertices \( X^{(k-1)} \) as well.

**Proof.** First, Condition \( (I_{k-1}) \) for \( v \) implies the same condition for \( \partial_k(v) \), since removing a factor \( S_k \) does not ruin decomposability. Let us prove that Condition \( (II_{k-1}) \) holds for \( \partial_k(v) \). We should check that for each \( j < k \) such that \( S_j \) is not present in \( \partial_k(v) \), there exists \( i < j \) for which \( \partial_i(\partial_k(v) \wedge S_j) \) is indecomposable. Since Condition \( (II_{k-1}) \) holds for \( v \), for each \( j < k \) not present in \( v \) we can find \( i < j \) such that \( \partial_i(v \wedge S_j) \) is indecomposable. By \( (I_{k-1}) \), \( \partial_i(v) \) is decomposable. Therefore, \( S_i \cap S_j \neq \emptyset \), and since we work with an Anick numbering we have \( S_i \cap S_k \subset S_j \cap S_k \). This means that \( \partial_i(\partial_k(v) \wedge S_j) \) is indecomposable (the only reason for \( \partial_i(v \wedge S_j) \) to become decomposable after removing \( S_k \) would be that something covered by both \( S_i \) and \( S_k \) wasn’t covered anymore, but the intersection of these divisors is covered by \( S_j \)).

Let us examine Condition \( (II_k) \) for a basis element \( v \), and for \( j = k \). Assume that it does not hold, so that \( S_k \) does not occur in \( v \), and for all \( i < k \) such that \( S_i \) present in \( v \wedge S_k \) the element \( \partial_i(v \wedge S_i) \) is decomposable. We shall now show that \( \pm v \wedge S_k \) and \( v \) will have been matched when forming the matching \( M_k \). Indeed, by our assumption Condition \( (I_{k-1}) \) holds for the monomial \( \pm v \wedge S_k \). Condition \( (II_{k-1}) \) holds for this monomial trivially, since it holds for \( v \), and indecomposability is preserved by the operators of wedge multiplication by \( S_p \). Thus, the monomial \( \pm v \wedge S_k \) belongs to \( X^{(k-1)} \) by induction, and we found an edge of the matching \( M_k \).
Vice versa, let us assume that Conditions (I\(_k\)) and (II\(_k\)) hold. Then Conditions (I\(_{k-1}\)) and (II\(_{k-1}\)) also hold, and so \(v \in X^{(k-1)}\) by induction. If \(v \notin X^{(0)}\), \(v\) is used in one of the edges of the matching \(M_k\). Condition (I\(_k\)) guarantees that no edge \(v \rightarrow w\) can appear on that step, so the only option is an edge \(\pm v \wedge S_k \rightarrow v\).

But by condition (II\(_k\)), there exists \(i < k\) for which \(\partial_i(v \wedge S_k)\) is indecomposable, which shows that \(v \wedge S_k\) would have been used at an earlier stage.

\[\square\]

**Proposition 3.7.** The matching \(M = \bigcup M_i\) is a Morse matching.

**Proof.** The only condition we need to check is acyclicity, since every vertex is involved in at most one edge by the construction. Suppose that there is a directed cycle in the graph \(\Gamma'\). Because it is a cycle, it has the same number of “increasing edges”, that is reversed \(M\)-edges, and decreasing edges, that is edges from \(E \setminus M\). For the rest of the proof, we choose an edge \(e = (v \rightarrow \pm v \wedge S_k)\) of our cycle with the largest possible \(k\).

Suppose that the edge following \(e\) is a decreasing one, that is we have a fragment \(v \rightarrow \pm v \wedge S_k \rightarrow \pm \partial(v \wedge S_k)\) in our cycle. Clearly, \(l \neq k\), since otherwise we would have the same edge belonging both to \(M\) and the reversion of \(M\), a contradiction. Also, it cannot be \(l > k\), since otherwise we would have found an edge \(u \rightarrow \pm u \wedge S_l\), which would contradict the definition of \(k\). Therefore, \(l < k\). But in this case, applying Condition (I\(_{k-1}\)) with \(j = l\) to the monomial \(v \wedge S_k\) we obtain a decomposable element, which is a contradiction.

Now suppose that the edge following \(e\) is an increasing one, that is we have a fragment \(v \rightarrow \pm v \wedge S_k \rightarrow \pm v \wedge S_k \wedge S_l\) in our cycle. Clearly, \(l \neq k\), since otherwise we have \(v \wedge S_k \wedge S_l = 0\). Then, according to the definition of \(k\), we have \(l < k\). Let us look at the element \(v \wedge S_k\). Since \(S_l\) is not present in it, we apply Condition (II\(_{k-1}\)) with \(j = l\) to this element, concluding that for some \(r < l\) the monomial \(\partial_r(v \wedge S_k \wedge S_l)\) is indecomposable. If we choose the smallest \(r\) for which \(\partial_r(v \wedge S_k \wedge S_l)\) is indecomposable, we observe that the monomials \(v \wedge S_k \wedge S_l\) and \(\pm \partial_r(v \wedge S_k \wedge S_l)\) were matched on the step \(r\). This contradicts the fact that \(v \wedge S_k \wedge S_l\) is matched with \(\pm S_k\).

\[\square\]

To complete the proof of Theorem 3.4, it is enough to show that the Morse differential \(d^M\) on the critical vertices is identically zero. This would mean that the critical vertices are precisely the homology classes of the chain complex \((\mathcal{A}_G)^{[0]}\).

The former statement can be proved as follows. Every path between two vertices in the graph \(\Gamma'\) starts either with an edge from \(E \setminus M\) or with a reversed edge from \(M\). No edge from \(E\), in particular an edge from \(E \setminus M\) can start with a critical vertex \(v\), since Conditions (I\(_k\)) altogether mean that for every \(k\) the monomial \(\partial_k v\) is decomposable, and consequently \(d(v) = 0\) in \((\mathcal{A}_G)^{[0]}\). No reversed edge from \(M\) can contain a critical vertex either, for tautological reasons.

\[\square\]

We proceed with our examples of Anick numberings. In the case discussed in Example 3.2, we shall, as we already mentioned, obtain Anick chains for...
monomial algebras [1, 61]. Let us recall their definition. Every chain is a monomial of the free algebra $k(x_1, \ldots, x_n)$. For $q \geq 0$, $q$-chains and their tails are defined inductively as follows:

- each generator $x_i$ is a 0-chain; it coincides with its tail;
- each $q$-chain is a monomial $m$ equal to a product $nst$ where $t$ is the tail of $m$, and $ns$ is a $(q-1)$-chain whose tail is $s$;
- in the above decomposition, the product $st$ has exactly one divisor which is a relation of $R$; this divisor is a right divisor of $st$.

In other words, a $q$-chain is a monomial formed by linking one after another $q$ relations so that only neighbouring relations are linked, the first $(q-1)$ of them form a $(q-1)$-chain, and no proper left divisor is a $q$-chain. In our notation above, such a monomial $m$ corresponds to the generator $m \otimes S_1 \wedge \cdots \wedge S_q$ where $S_1, \ldots, S_q$ are the relations we linked.

**Proposition 3.8.** For the Anick numbering of divisors from Example 3.2, the representatives for homology classes suggested by Theorem 3.4 are precisely Anick chains.

**Proof.** Indeed, condition (I) means that only neighbours are linked, and condition (II) means that no proper beginning of a $q$-chain forms a $q$-chain. □

**Remark 3.9.** If we consider the numbering of subwords according to the position of their last letters, we obtain another Anick numbering. The fact that both of the numberings are Anick numberings can be used to obtain a conceptual proof of a result of Bardzell [2, 3] who observed that “Anick left chains” and “Anick right chains” have the same set of underlying monomials, and used it to obtain a resolution of $A$ as an $A - A$-bimodule for an algebra $A$ with monomial relations.

In the setup of our second example, we shall in fact obtain a combinatorial picture modelled on Anick chains as well. Recall that we are dealing with an operad $\mathcal{O} = \mathcal{F}_\mathcal{A}/(\mathcal{G})$ is an operad with binary generators and monomial relations all of which are left and right combs, and assume that we fix an Anick numbering of the kind described in Proposition 3.3.

**Definition 3.10.** To a tree monomial $T$ made up of generators of $\mathcal{O}$, we associate a set of maximal combs. A maximal left comb of $T$ is a sequence of internal vertices $a_1, \ldots, a_q$ of $T$ for which the left child of $a_q$ is a leaf, the left child of $a_l$ is $a_{l+1}$ for $1 \leq l \leq q - 1$, and the parent of $a_l$ (if any) has $a_l$ as its right vertex. Maximal right combs are defined similarly.

Clearly, for every indecomposable monomial of the operad $\mathcal{A}_\mathcal{G}$ each maximal left comb of the underlying tree monomial must be covered by left combs from $\mathcal{G}$, and each maximal right comb of the underlying tree monomial must be covered by right combs from $\mathcal{G}$.
**Definition 3.11.** A monomial in $\mathcal{A}_G$ is said to be an *Anick chain* for $\mathcal{O}$ if for each of its maximal combs its covering by combs from $\mathcal{G}$ obeys the pattern governing Anick chains for associative algebras.

The definitions are given in such a way that following result is proved completely analogously to Proposition 3.8.

**Proposition 3.12.** Suppose that $\mathcal{O} = \mathcal{F}_M / (\mathcal{G})$ is an operad with binary generators and monomial relations, $\mathcal{G} = \mathcal{G}_l \cup \mathcal{G}_r$ where $\mathcal{G}_l$ consists of left combs and $\mathcal{G}_r$ consists right combs, and at least one of the sets $\mathcal{G}_l$, $\mathcal{G}_r$ is contained in $\mathcal{F}_M(3)$. The representatives for homology classes of $\mathcal{O}$ suggested by Theorem 3.4 are precisely Anick chains.

### 4 Resolution for general relations

Let $\widetilde{\mathcal{O}} = \mathcal{F}_\mathcal{M} / (\mathcal{G})$ be an operad, and let $\mathcal{O} = \mathcal{F}_\mathcal{M} / (\mathcal{G})$ be its monomial replacement, that is, $\mathcal{F}$ is a Gröbner basis of relations, and $\mathcal{G}$ consists of all leading monomials of $\mathcal{F}$. In Section 2, we defined a free resolution $(\mathcal{A}_G, d)$ for $\mathcal{O}$, so that $H(A_G, d) \cong \mathcal{O}$.

Let $\phi$ be the canonical homomorphism from $\mathcal{A}_G$ to its homology $\mathcal{O}$ (it kills all generators of positive homological degree, and on elements of homological degree 0 is the canonical projection from $\mathcal{F}_M$ to its quotient). Tree monomials that are not divisible by any of the monomial relations $\mathcal{G}$ form a basis of $\mathcal{O}$, and we define a map $\pi$ as the composition of $\phi$ with the corresponding section; it sends elements of homological degree zero to their residues modulo $\mathcal{G}$, represented as linear combinations of tree monomials not divisible by $\mathcal{G}$ in our resolution. Since $(\mathcal{A}_G, d)$ is a resolution of $\mathcal{O}$, there exists a contracting homotopy $h$ for this resolution, so that $(dh)|_{\ker d} = \text{id} - \pi$ (in fact, below we shall specify a particular choice for such homotopy). Our goal is to “deform” this statement in the following sense. Let $\widetilde{\phi}$ be the homomorphism from $\mathcal{A}_G$ to $\widetilde{\mathcal{O}}$ that kills all generators of positive homological degree, and on elements of homological degree 0 is the canonical projection from $\mathcal{F}_\mathcal{M}$ to its quotient $\widetilde{\mathcal{O}} = \mathcal{F}_\mathcal{M} / (\mathcal{G})$. By general results on Gröbner bases, tree monomials that are not divisible by any of the leading terms $\mathcal{G}$ of relations $\mathcal{F}$ form a basis of $\mathcal{O}$ (each element $f$ of the free operad $\mathcal{F}_\mathcal{M}$ is represented as its residue $\overline{f}$ modulo the Gröbner basis $\overline{\mathcal{G}}$), and we define a map $\overline{\pi}$ as the composition of $\overline{\phi}$ with the corresponding section; it sends elements of homological degree zero to their residues modulo $\mathcal{G}$, represented as linear combinations of tree monomials not divisible by $\mathcal{G}$ in our resolution.

We shall prove the following result, which is essentially nothing but homological perturbation in the same way as it is used in the case of free resolutions of trivial modules over augmented associative algebras in [1, 35, 38].
**Theorem 4.1.** There exists a “deformed” differential $D$ on $\mathcal{A}_g$ and a homotopy 

$$H : \ker D \to \mathcal{A}_g$$

such that 

$$H(\mathcal{A}_g, D) \simeq \overline{\partial} \quad \text{and} \quad (DH)_{\ker D} = \text{id} - \overline{\eta}.$$ 

**Proof.** We shall construct $D$ and $H$ simultaneously by induction. Let us introduce a partial ordering of basis elements in $\mathcal{A}_g$ which just compares the underlying tree monomials. This partial ordering suggests the following definition: for an element $u \in \mathcal{A}_g$, its leading term $\hat{u}$ is the part of the expansion of $u$ as a combination of basis elements where we keep only basis elements $T \otimes S_1 \wedge \cdots \wedge S_q$ with maximal possible $T$.

If $L$ is a homogeneous linear operator on $\mathcal{A}_g$ of some fixed (homological) degree of homogeneity (like $D, H, d, h$), we denote by $L_k$ the operator $L$ acting on elements of homological degree $k$. We shall define the operators $D$ and $H$ by induction: we define the pair $(D_{k+1}, H_k)$ assuming that all previous pairs are defined. At each step, we shall also be proving that

$$D(x) = d(x) + \text{lower terms}, \quad H(x) = h(x) + \text{lower terms},$$

where the words “lower terms” refers to the partial order we defined above, meaning a linear combination of basis elements whose underlying tree monomial is smaller than the underlying tree monomial of $\hat{x}$.

**Basis of induction:** $k = 0$, so we have to define $D_1$ and $H_0$ (note that $D_0 = 0$ because there are no elements of negative homological degrees). In general, to define $D_k$, we should only consider the case where our element is a generator of $\mathcal{A}_g$, since in a dg operad the differential is defined by images of generators. For $l = 1$, this means that we should consider the case where our generator corresponds to a leading monomial $T = \text{lt}(g)$ of some relation $g$, and is of the form $T \otimes S$ where $S$ corresponds to the only divisor of $T$ which is a leading term, that is $T$ itself. Letting $D_1(T \otimes S) = \frac{1}{c_g} g$, where $c_g$ is the leading coefficient of $g$, we see that $D_1(T \otimes S) = T + \text{lower terms}$, as required. To define $H_0$, we use a yet another inductive argument, decreasing the monomials on which we want to define $H_0$. First of all, if a tree monomial $T$ is not divisible by any of the leading terms of relations, we put $H_0(T) = 0$. Assume that $T$ is divisible by some leading terms of relations, and $S_1, \ldots, S_p$ are the corresponding divisors. Then on $\mathcal{A}_g$ we can use $S_1 \wedge \cdots$ as a homotopy, so $h_0(T) = T \otimes S_1$. We put

$$H_0(T) = h_0(T) + H_0(T - D_1 h_0(T)).$$

Here the leading term of $T - D_1 h_0(T)$ is smaller than $T$ (since we already know that the leading term of $D_1 h_0(T)$ is $d_1 h_0(T) = T$), so induction on the leading term applies. Note that by induction the leading term of $H_0(T)$ is $h_0(T)$. 

Suppose that $k > 0$, that we know the pairs $(D_{l+1}, H_l)$ for all $l < k$, and that in these degrees

$$D(x) = d(\hat{x}) + \text{lower terms}, \quad H(x) = h(\hat{x}) + \text{lower terms}.$$
To define $D_{k+1}$, we should, as above, only consider the case of generators. In this case, we put

$$D_{k+1}(x) = d_{k+1}(x) - H_{k-1}D_k d_{k+1}(x).$$

The property $D_{k+1}(x) = d_{k+1}(x) + \text{lower terms}$ now easily follows by induction.

To define $H_k$, we proceed in a way very similar to what we did for the induction basis. Assume that $u \in \ker D_k$, and that we know $H_k$ on all elements of $\ker D_k$ whose leading term is less than $\hat{u}$. Since $D_k(u) = d_k(\hat{u}) + \text{lower terms}$, we see that $u \in \ker D_k$ implies $\hat{u} \in \ker d_k$. Then $h_k(\hat{u})$ is defined, and we put

$$H_k(u) = h_k(\hat{u}) + H_k(u - D_{k+1}h_k(\hat{u})).$$

Here $u - D_{k+1}h_k(\hat{u}) \in \ker D_k$ and its leading term is smaller than $\hat{u}$, so induction on the leading term applies (and it is easy to check that by induction $H_{k+1}(x) = h_{k+1}(x) + \text{lower terms}$).

Let us check that the mappings $D$ and $H$ defined by these formulas satisfy, for each $k > 0$, $D_k D_{k+1} = 0$ and $(D_{k+1}H_k)_{\ker D_k} = \text{id} - \bar{\pi}$. A computation checking that is somewhat similar to the way $D$ and $H$ were constructed. Let us prove both statements simultaneously by induction. If $k = 0$, the first statement is obvious. Let us prove the second one and establish that $D_1 H_0(T) = (\text{id} - \bar{\pi})(T)$ for each tree monomial $T$. Slightly rephrasing that, we shall prove that for each tree monomial $T$ we have $D_1 H_0(T) = T - \bar{T}$ where $\bar{T}$ is the residue of $T$ modulo $\mathcal{G}$ [13]. We shall prove this statement by induction on $T$. If $T$ is not divisible by any leading terms of relations, we have $H_0(T) = 0 = T - \bar{T}$. Let $T$ have divisors $S_1, \ldots, S_p$. We have $H_0(T) = h_0(T) + H_0(T - D_1 h_0(T))$, so

$$D_1 H_0(T) = D_1 h_0(T) + D_1 H_0(T - D_1 h_0(T)).$$

By induction, we may assume that

$$D_1 H_0(T - D_1 h_0(T)) = T - D_1 h_0(T) - \bar{(T - D_1 h_0(T))}.$$

Also,

$$D_1 h_0(T) = D_1 (T \otimes S_1) = \frac{1}{c_g} m_{T, S_1}(g) = T - r_g(T).$$

Here we use the usual notation for Gröbner bases computations [13]: $r_g(T)$ is the result of reduction of $T$ modulo $g$, and $m_{T, S_1}(g)$ denotes the result of the substitution of $g$ into $T$ at that place (we have $D_1 (T \otimes S_1) = \frac{1}{c_g} m_{T, S_1}(g)$ since it is true when $T$ is a relation, and the differential agrees with operadic compositions).

Combining the three previous equations, we obtain,

$$D_1 H_0(T) = T - r_g(T) + \bar{(T - D_1 h_0(T))} - \bar{(T - D_1 h_0(T))} = T - r_g(T) + (r_g(T) - r_g(T)) = T - r_g(T) = T - \bar{T},$$

$$\text{(id} - \bar{\pi})(T).$$
since for a Gröbner basis the residue does not depend on a choice of reductions. Assume that \( k > 0 \), and that our statement is true for all \( l < k \). We have

\[ D_k D_{k+1}(x) = 0 \]

since

\[
D_k D_{k+1}(x) = D_k(d_{k+1}(x) - H_{k-1}D_k d_{k+1}(x)) = \\
= D_k d_{k+1}(x) - D_k D_k d_{k+1}(x) = D_k d_{k+1}(x) - D_k d_{k+1}(x) = 0,
\]

because \( D_k d_{k+1} k \in \ker D_{k-1} \), and so \( D_k H_{k-1}(D_k(y)) = D_k(y) \) by induction. Also, for \( u \in \ker D_k \) we have

\[ D_{k+1} H_k(u) = D_{k+1} h_k(\tilde{u}) + D_{k+1} H_k(u - D_{k+1} h_k(\tilde{u})), \]

and by the induction on \( \tilde{u} \) we may assume that

\[ D_{k+1} H_k(u - D_{k+1} h_k(\tilde{u})) = u - D_{k+1} h_k(\tilde{u}) \]

(on elements of positive homological degree, \( \pi = 0 \)), so

\[ D_{k+1} H_k(u) = D_{k+1} h_k(\tilde{u}) + u - D_{k+1} h_k(\tilde{u}) = u, \]

which is exactly what we need. \( \square \)

5 Applications

5.1 Another proof of the PBW criterion for Koszulness

The goal of this section is to give a new proof of the Gröbner bases formulation [13] version of the PBW criterion of Hoffbeck [31] (generalising the PBW criterion of Priddy [51] for associative algebras).

**Theorem 5.1.** An operad with a quadratic Gröbner basis is Koszul.

**Proof.** First of all, it is enough to prove it in the monomial case, since it gives an upper bound on the homology: for the deformed differential, the cohomology may only decrease. In the monomial quadratic case, every divisor of a tree monomial covers one internal edge, and every internal edge is covered by precisely one divisor, so all the generators of our free resolution are of homological degree one less than the number of corollas used in them, hence the homology of the bar complex is concentrated on the diagonal, and our operad is Koszul. \( \square \)
5.2 Operads and commutative algebras

Recall a construction of an operad from a graded commutative algebra described in [33].
Let $A$ be a connected graded associative commutative algebra. Define an operad $\mathcal{O}_A$ as follows. We put
\[ \mathcal{O}_A(I) := A|_{|I| - 1}, \]
and define, for each shuffle surjection $\phi: I \rightarrow \{1, \ldots, k\}$, the composition map
\[ o_\phi: \mathcal{P}(k) \otimes \mathcal{P}(\phi^{-1}(1)) \otimes \cdots \otimes \mathcal{P}(\phi^{-1}(k)) \rightarrow \mathcal{P}(I) \]
to be the product in $A$:
\[ a \circ_\phi (b_1, \ldots, b_k) = ab_1 \cdots b_k. \]
The arities of the elements match: since $I = \bigsqcup_{i=1}^{k} \phi^{-1}(i)$, we have $|I| - 1 = k - 1 + (|\phi^{-1}(1)| - 1) + \cdots + (|\phi^{-1}(k)| - 1)$. (In the symmetric case, we have also to define the actions of symmetric groups; by definition, all the components of $\mathcal{O}_A$ are trivial representations of the respective symmetric groups.)
As we remarked in [13], a basis of the algebra $A$ leads to a basis of the operad $\mathcal{O}_A$: product of generators of the polynomial algebra is replaced by the iterated composition of the corresponding generators of the free operad where each composition is substitution into the last slot of an operation. Assume that we know a Gröbner basis for the algebra $A$ (as an associative algebra). It leads to a Gröbner basis for the operad $\mathcal{O}_A$ as follows: we first impose the quadratic relations defining the operad $\mathcal{O}_A/CZ_{\{x_1, \ldots, x_n\}}$ coming from the polynomial algebra (stating that the result of a composition depends only on the operations composed, not on the order in which we compose operations), and then use the identification of relations in the polynomial algebra with elements of the corresponding operad, as above. Our next goal is to explain how to use the Anick resolution of the trivial module for $A$ to construct a small resolution of the trivial module for $\mathcal{O}_A$.
Let us define a collection $\mathcal{R}$ which will then use to construct a resolution. We take the free operad generated by the collection $\mathcal{H}$ with $s^{-1} \mathcal{H}(k) = H^Q_{k-2}(A)$. We take $\mathcal{R}$ to be the quotient of that operad by the relations $c_1 \circ_2 c_2 = 0$, where $c_1 \in \mathcal{H}(k)$. In other words, in $\mathcal{R}$ all compositions are allowed except for those using the last slot of an operation. We shall show that $\mathcal{R}$ gives an upper bound on the Quillen homology of $\mathcal{O}_A$ by proving the following theorem.

**Theorem 5.2.** There exists a free resolution $(\mathcal{F}_{\mathcal{R}}, d) \rightarrow \mathcal{O}_A$.

**Proof.** This statement is almost immediate from our previous results. Indeed, we know how to obtain a Gröbner basis for $\mathcal{O}_A$ from a Gröbner basis of $A$. The leading terms of that Gröbner basis are all left combs
\[ a(\beta(1, 2), 3) \quad \text{and} \quad a(\beta(1, 3), 2) \]
with three leaves and some right combs

\[ \alpha_1(1, \alpha_2(2, \ldots \alpha_k(k, k+1)), \ldots) \].

By Proposition 3.12, the corresponding homology classes of the associated monomial operad can be described by elements of the same shape as defined above, but we should start with the operad generated by Anick chains [1], not by the homology. To understand what happens in the transition from the monomial replacement to \( \mathcal{O}_A \), let us look carefully into the general reconstruction scheme from the previous section. It recovers lower terms of differentials and homotopies by recalling lower terms of elements of the Gröbner basis. Let us do the reconstruction in two steps. At first, we shall recall all lower terms of relations except for those starting with \( \alpha(\beta(-, -), -) \); the latter are still assumed to vanish. On the next step we shall recall all lower terms of those quadratic relations. Note that after the first step we model many copies of the associative algebra resolution and the differential there; so we can compute the homology explicitly. At the next step, a differential will be induced on this homology we computed, and we end up with a resolution of the required type.

In some cases the existence of such a resolution is enough to compute Quillen homology of \( \mathcal{O}_A \); for example, it is so when the algebra \( A \) is Koszul, as we shall see now. In general, the differential of this resolution incorporates lots of information, including the higher operations (Massey (co)products) on the homology of \( A \).

Recall that if the algebra \( A \) is quadratic, then the operad \( \mathcal{O}_A \) is quadratic as well. In [13], we proved that if the algebra \( A \) is PBW, then the operad \( \mathcal{O}_A \) is PBW as well, and hence is Koszul. Now we shall prove the following substantial generalisation of this statement (substantially simplifying the proof of this statement given in [33]).

**Theorem 5.3.** If the algebra \( A \) is Koszul, then the operad \( \mathcal{O}_A \) is Koszul as well.

**Proof.** Koszulness of our algebra implies that the homology of the bar resolution is concentrated on the diagonal. Consequently, the operad \( \mathcal{R} \) constructed above is automatically concentrated on the diagonal, and so is its homology, which completes the proof.

5.3 **The operads of Rota–Baxter algebras**

The main goal of this section is to compute Quillen homology for the operad of Rota–Baxter algebras, and the operad of noncommutative Rota–Baxter algebras. Those are among the simplest examples of operads which are not covered by the Koszul duality theory, being operads with nonhomogeneous relations. Note that it is even not clear that these operads have minimal models: being operads with nontrivial unary operations, they are not covered by results of [47], and indeed some operads with nontrivial unary operations do not admit minimal models.
5.3.1 The operads \( \text{RB} \) and \( \text{ncRB} \) and their Gröbner bases

**Definition 5.4.** A commutative Rota–Baxter algebra of weight \( \lambda \) is a vector space with an associative commutative product \( a, b \mapsto a \cdot b \) and a unary operator \( P \) which satisfy the following identity:

\[
P(a) \cdot P(b) = P(P(a) \cdot b + a \cdot P(b) + \lambda a \cdot b).
\]

We denote by \( \text{RB} \) the operad of Rota–Baxter algebras. We view it as a shuffle operad with one binary and one unary generator.

Commutative Rota–Baxter algebras were defined in [57] with a motivation coming from probability theory [4]. Various constructions of free commutative Rota–Baxter algebras appear in [57, 9, 28]. The latter paper also contains extensive bibliography and information on various applications of those algebras.

**Definition 5.5.** A noncommutative Rota–Baxter algebra of weight \( \lambda \) is a vector space with an associative product \( a, b \mapsto a \cdot b \) and a unary operator \( P \) which satisfy the same identity as above:

\[
P(a) \cdot P(b) = P(P(a) \cdot b + a \cdot P(b) + \lambda a \cdot b).
\]

We denote by \( \text{ncRB} \) the operad of noncommutative Rota–Baxter algebras. Somehow, it is a bit simpler than the operad in the commutative case, because it can be viewed as a non-symmetric operad with one binary and one unary generator.

Noncommutative Rota–Baxter algebras has been extensively studied in the past years. We refer the reader to the paper of Ebrahimi–Fard and Guo [18] for an extensive discussion of applications and occurrences of those algebras in various areas of mathematics, and a combinatorial construction of the corresponding free algebras.

Let us consider the path-lexicographic ordering of the free operad; we assume that \( P > \cdot \).

**Proposition 5.6.** The defining relations for operads \( \text{RB} \) and \( \text{ncRB} \) form a Gröbner basis.

**Proof.** Here we present a proof for the case of \( \text{ncRB} \), the proof for \( \text{RB} \) is essentially the same, with the only exception that there are two S-polynomials to be reduced, as opposed to one S-polynomial in the case of \( \text{ncRB} \) (which, as we pointed above, is easier because we are dealing with a non-symmetric operad). For the associative suboperad of \( \text{ncRB} \), the defining relations form a Gröbner basis, so the S-polynomials coming from the small common multiples the leading term of the associativity relation has with itself clearly can be reduced to zero. The leading term of the Rota–Baxter relation is \( P(P(a_1)a_2) \). This term only has a nontrivial overlap with itself, not with the leading term of the
associativity relation, and that overlap is $P(P(a_1 \cdot a_2) \cdot a_3)$. From this overlap, we compute the S-polynomial

$$-P(P(a_1 \cdot P(a_2)) \cdot a_3) - \lambda P(P(a_1 \cdot a_2) \cdot a_3) + P((P(a_1) \cdot P(a_2)) \cdot a_3) + P((P(a_1) \cdot a_2) \cdot P(a_3)) + \lambda P((P(a_1) \cdot a_2) \cdot a_3) - P(P(a_1) \cdot a_2) \cdot P(a_3),$$

and it can be reduced to zero by a lengthy sequence of reductions which we omit here (but which in fact can be read from the formula for $d_{\nu_3}$ in Proposition 5.11 below). By Diamond Lemma [13], our relations form a Gröbner basis. □

**Remark 5.7.** In the case of the operad $n\text{cRB}$, our computation immediately provides bases for free noncommutative Rota–Baxter algebras. Indeed, since our operad is non-symmetric, the degree $n$ part of the free noncommutative Rota–Baxter algebra generated by the set $B$ is nothing but $n\text{cRB}(n) \otimes V^\otimes n$, where $V = \text{span}(B)$, so we can use the above Gröbner basis to describe that part. More precisely, we first define the set of admissible expressions on a set $B$ recursively as follows:

- elements of $B$ are admissible expressions;
- if $b$ is an admissible expression, then $P(b)$ is an admissible expression;
- if $b_1, \ldots, b_k$ are admissible expressions, and for each $i$ either $b_i$ is an element of $B$ or $b_i = P(b'_i)$ with $b'_i$ an admissible expression, then their associative product $b_1 \cdot b_2 \cdots b_k$ is an admissible expression.

Based on this definition, we shall call some of admissible expressions the Rota–Baxter monomials, tracing the construction of an admissible expression and putting some restrictions. Namely,

- elements of $B$ are Rota–Baxter monomials;
- if $b$ is a Rota–Baxter monomial, which, as an admissible expression, is either $b = P(b')$ or $b = b_1 \cdot b_2 \cdots b_k$ with $b_1 \in B$, then $P(b)$ is a Rota–Baxter monomial;
- if $b_1, \ldots, b_k$ are Rota–Baxter monomials, and for each $i$ either $b_i \in B$ or $b_i = P(b'_i)$ for some $b'_i$, then their associative product $b_1 \cdot b_2 \cdots b_k$ is a Rota–Baxter monomial.

Our previous discussion means that the set of all Rota–Baxter monomials forms a basis in the free noncommutative Rota–Baxter algebra generated by the set $B$. It would be interesting to compare this basis with the basis from [19].
5.3.2 Quillen homology of the operads $RB$ and $ncRB$

**Proposition 5.8.** For each of the operads $RB$ and $ncRB$, the resolution for its monomial version from Section 2 is minimal, that is the differential induced on the space of generators is zero.

*Proof.* In the case of the operad $RB$, the overlaps obtained from the leading monomials $(a_1 \cdot a_2) \cdot a_3$, $(a_1 \cdot a_3) \cdot a_2$, and $P(a_1) \cdot a_2$ are, in arity $n$,

$$(\ldots((a_i \cdot a_k) \cdot a_l)\ldots) \cdot a_m$$

and

$$P(P(\ldots P(P(a_i) \cdot a_k) \cdot a_l)\ldots) \cdot a_m),$$

for all permutations $i_2, i_3, \ldots, i_n$ of integers $2, 3, \ldots, n$. It is easy to see that for each of them there exists only one indecomposable covering by relations, so the differential maps such a generator to the space of decomposable elements, and the statement follows.

Similarly, in the case of the operad $ncRB$, the only overlaps obtained from the leading monomials $(a_1 \cdot a_2) \cdot a_3$ and $P(a_1) \cdot a_2$ are, in arity $n$,

$$(\ldots((a_1 \cdot a_2) \cdot a_3)\ldots) \cdot a_{n-1} \cdot a_n$$

and

$$P(P(\ldots P(P(a_1) \cdot a_2) \cdot a_3)\ldots) \cdot a_{n-1} \cdot a_n).$$

It is easy to see that for each of them there exists only one indecomposable covering by relations, so the differential maps such a generator to the space of decomposable elements, and the statement follows. 

**Theorem 5.9.** We have

$$\dim H^Q_l(RB)(k) = \begin{cases} (k - 1)!, & l = k \geq 1, \\ (k - 1)! , & l = k + 1 \geq 2. \end{cases}$$

$$\dim H^Q_l(ncRB)(k) = \begin{cases} 1, & l = k \geq 1, \\ 1, & l = k + 1 \geq 2. \end{cases}$$

*Proof.* In both cases, the subspace of generators of the free resolution splits into two parts: the part obtained as overlaps of the leading terms of the associativity relations, and the part obtained as overlaps of the leading term of the Rota–Baxter relation with itself. In arity $k$, the former are all of homological degree $k - 1$, while the latter — of homological degree $k$. This means that when we compute the homology of the differential of our resolution restricted to the space of generators, the only cancellations can happen if some of the elements resolving the associativity relation appear as differentials of some elements resolving the Rota–Baxter relation. However, since all monomials in the Rota–Baxter relation are of degree at least 1 in $P$, the way the deformed differential
is constructed in the proof of Theorem 4.1 shows that all the terms appearing in the formulas for the respective differentials are also of degree at least 1 in $P$, so no cancellations are possible.

In addition to Quillen homology computation, one can ask for explicit formulas for differentials in the free resolutions. It is not difficult to write down formulas for small arities (see the example below), but in general compact formulas are yet to be found. We expect that they incorporate the Spitzer’s identity and its noncommutative analogue [20]. However, the following statement is immediate.

**Corollary 5.10.**

- The minimal model $RB_{\infty}$ for the operad $RB$ is a quasi-free operad whose space of generators has a $(k-1)!$-dimensional space of generators of homological degree $(k-2)$ in each arity $k \geq 2$, and a $(k-1)!$-dimensional space of generators of homological degree $k-1$ in each arity $k \geq 1$.

- The minimal model $ncRB_{\infty}$ for the operad $ncRB$ is a quasi-free operad generated by operations $\mu_k$, $k \geq 2$ of arity $k$ and homological degree $k-2$, and $\nu_l$, $l \geq 1$ of arity $l$ and homological degree $l-1$.

Let us conclude this section with formulas for low arities differentials in $ncRB_{\infty}$, to give the reader a flavour of what sort of formulas to expect.

**Example 5.11.** We have $d\nu_1 = d\mu_2 = 0$, and

$$
d\nu_2 = P(\mu_2(P(\cdot), \cdot)) + P(\mu_2(\cdot, P(\cdot))) - \mu_2(P(\cdot), P(\cdot)) + \lambda P(\mu_2(\cdot, \cdot)),
\quad d\mu_3 = \mu_2(\mu_2(\cdot, \cdot), \cdot) - \mu_2(\cdot, \mu_2(\cdot, \cdot)),
$$

$$
d\nu_3 = \mu_3(P(\cdot), P(\cdot), P(\cdot)) - P(\mu_2(\nu_2(\cdot, \cdot), \cdot) - \mu_2(\cdot, \nu_2(\cdot, \cdot))) -
\quad - P(\mu_3(P(\cdot), P(\cdot), \cdot)) + \mu_3(\cdot, P(\cdot), P(\cdot)) + \mu_3(\cdot, P(\cdot), P(\cdot)) +
\quad + \nu_2(\mu_2(P(\cdot), \cdot) - \nu_2(\cdot, \mu_2(\cdot, \cdot)) + \nu_2(\cdot, P(\cdot), \cdot) + \nu_2(\cdot, \cdot, P(\cdot))) +
\quad + \mu_2(\nu_2(\cdot, \cdot), P(\cdot)) - \mu_2(P(\cdot), \nu_2(\cdot, \cdot)) + \lambda [\nu_2(\mu_2(\cdot, \cdot), \cdot) - \nu_2(\cdot, \mu_2(\cdot, \cdot)) -
\quad - P(\mu_3(P(\cdot), \cdot, \cdot) + \mu_3(\cdot, P(\cdot), \cdot) + \mu_3(\cdot, \cdot, P(\cdot))) - \lambda^2 P(\mu_3(\cdot, \cdot, \cdot)).
$$

### 5.4 The operad $BV$ and hypercommutative algebras

The main goal of this section is to explain how our results can be used to study the operad $BV$ of Batalin–Vilkovisky algebras. The key result below (Theorem 5.18) is also proved in [17]; our proofs are based on entirely different methods.

#### 5.4.1 The operad $BV$ and its Gröbner basis.

Batalin–Vilkovisky algebras show up in various questions of mathematical physics. In [23], a cofibrant resolution for the corresponding operad was presented. However, that resolution is a little bit more that minimal. In this
section, we present a minimal resolution for this operad in the shuffle category. The operad $BV$, as defined in most sources, is an operad with quadratic–linear relations: the odd Lie bracket can be expressed in terms of the product and the unary operator. However, alternatively one can say that a $BV$-algebra is a dg commutative algebra with a unary degree 1 operator $\Delta$ with $\Delta^2 = 0$ which is a differential operator of order at most 2. This definition of a $BV$-algebra is certainly not new, see, e. g., [24]. With this presentation, the corresponding operad becomes an operad with homogeneous relations (of degrees 2 and 3). Our choice of degrees and signs is taken from [23] where it is explained how to translate between this convention and other popular definitions of $BV$-algebras.

We write identities for operations evaluated on elements of degree 0, assuming the usual Koszul sign rule for evaluating operations on elements of arbitrary degrees. We want to emphasize that when computing Gröbner bases, we are dealing with operations only, and all signs arise from evaluating operations on elements. The representatives of the identities are chosen in such a way that they can be viewed as elements of the free shuffle operad; we use the language of operations, as opposed the language of tree monomials: for each $i$, the argument $a_i$ of an operation corresponds to the leaf $i$ of the corresponding tree monomial.

**Definition 5.12 (BV-algebras with homogeneous relations).** A Batalin-Vilkovisky algebra, or $BV$-algebra for short, is a differential graded vector space $(A, d_A)$ endowed with

- a symmetric binary product $\bullet$ of degree 0,
- a unary operator $\Delta$ of degree +1,

such that $(A, d_A, \Delta)$ is a mixed complex, $d_A$ is a derivation with respect to the product, and such that

- the product $\bullet$ is associative, $(a_1 \bullet a_2) \bullet a_3 = a_1 \bullet (a_2 \bullet a_3)$ and $(a_1 \bullet a_3) \bullet a_2 = a_1 \bullet (a_2 \bullet a_3)$
- the operator $\Delta$ satisfies $\Delta^2(a_1) = 0$,
- the operations satisfy the cubic identity

$$\Delta((a_1 \bullet a_2) \bullet a_3) = \Delta(a_1 \bullet a_2) \bullet a_3 + \Delta(a_1 \bullet a_3) \bullet a_2 + a_1 \bullet \Delta(a_2 \bullet a_3) - (\Delta(a_1) \bullet a_2) \bullet a_3 - (a_1 \bullet \Delta(a_2)) \bullet a_3 - (a_1 \bullet \Delta(a_3)) \bullet a_2,$$

Let us consider the ordering of the free operad where we first compare lexicographically the operations on the paths from the root to leaves, and then the planar permutations of leaves; we assume that $\Delta > \bullet$. 
Proposition 5.13. The above relations together with the degree 4 relation
\[
\Delta(a_1 \bullet \Delta(a_2 \bullet a_3)) + \Delta(\Delta(a_1 \bullet a_2) \bullet a_3) + \Delta(\Delta(a_1 \bullet a_3) \bullet a_2) - \\
\Delta((\Delta(a_1) \bullet a_2) \bullet a_3) - \Delta((a_1 \bullet \Delta(a_2)) \bullet a_3) - \Delta((a_1 \bullet \Delta(a_3)) \bullet a_2) = 0 \tag{1}
\]
form a Gröbner basis of relations for the operad of BV-algebras.

Proof. With respect to our ordering, the leading monomials of our original relations are 
\((a_1 \bullet a_2) \bullet a_3\), \((a_1 \bullet a_3) \bullet a_2\), \(\Delta^2(a_1)\), and 
\(\Delta(a_1 \bullet (a_2 \bullet a_3))\). The only small common multiple of \(\Delta^2(a_1)\) and 
\(\Delta(a_1 \bullet (a_2 \bullet a_3))\) gives a nontrivial S-polynomial which, is precisely the relation (1). The leading term of that relation is 
\(\Delta(\Delta(a_1 \bullet a_2) \bullet a_3)\).

It is well known that \(\dim BV(n) = 2^n n!\) [24], so to verify that our relations form a Gröbner basis, it is sufficient to show that the restrictions imposed by these leading monomials are enough. In other words, we may check that the number of arity \(n\) tree monomials that are not divisible by any of these is equal to \(2^n n!\). Moreover it is sufficient to check that for \(n \leq 4\), since all S-polynomials of our relations will be elements of arity at most 4. This can be easily checked by hand, or by a computer program [15]. □

5.4.2 Quillen homology of the operad BV

Let us denote by \(\mathcal{G}\) the Gröbner basis from the previous section.

Proposition 5.14. For the monomial replacement of BV, the resolution \(\mathcal{A}/\mathcal{G}\) from Section 2 is minimal, that is the differential induced on the space of generators is zero.

Proof. Let us describe explicitly the space of generators, that is possible indecomposable coverings of monomials by leading terms of relations (all monomials below are chosen from the basis of the free shuffle operad, so the correct ordering of subtrees is assumed). These are

- all monomials \(\Delta^k(a_1)\), \(k \geq 2\) (covered by several copies of \(\Delta^2(a_1)\)),
- all “left combs”
  \[
  \lambda = \left( (a_1 \bullet a_2) \bullet a_3 \right) \bullet \cdots \bullet a_n \tag{2}
  \]
  where \((k_2, \ldots, k_n)\) is a permutation of numbers 2, \ldots, \(n\), \(n \geq 3\) (only the leading terms \((a_1 \bullet a_2) \bullet a_3\) and \((a_1 \bullet a_3) \bullet a_2\) are used in the covering),
- all the monomials
  \[
  \Delta^2(\Delta(\lambda_1 \bullet (\lambda_2 \bullet a_i)))
  \]
  where \(k \geq 1\), each \(\lambda_i\) is a left comb as described above (so that several copies of \(\Delta^2\), the leading term of degree 3, and several leading terms of the associativity relations are used in the covering),
Quillen Homology for Operads via Gröbner Bases

- all monomials

\[ \Delta^k(\Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \lambda_3) \bullet \ldots) \bullet \lambda_n) \] (3)

where \( k \geq 0, \ n \geq 3, \) and \( \lambda_i \) are left combs (several copies of all leading terms are used, including at least one copy of the degree 4 leading term).

This is a complete list of tree monomials \( T \) for which \((\mathcal{A}_g)^P\) is nonzero in positive homological degrees. It is easy to see that for each of them there exists only one indecomposable covering by relations, that is only one generator of \( \mathcal{A}_g \) of shape \( T \). Consequently, the differential maps such a generator to a combination of decomposable elements, so the differential induced on generators is identically zero.

The resolution of the operad \( BV \) which one can derive by our methods from this one is quite small (in particular, smaller than the one of [23]) but still not minimal. However, we now have enough information to compute Quillen homology of the operad \( BV \).

**Theorem 5.15.** The basis of \( H^0(BV) \) is formed by monomials

\[ \Delta^k(a_1), \quad k \geq 1, \]

and all monomials of the form

\[ \Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \ldots) \bullet (\lambda_n \bullet a_j)), \quad n \geq 1 \]

from the resolution of the monomial replacement of \( BV \) discussed above. Here all \( \lambda_i \) are left combs.

**Proof.** First of all, let us notice that since \( \Omega(B(BV)) \), a free operad generated by \( B(BV)[-1] \), provides a resolution for \( BV \), the space \( H^0(BV)[-1] \) is the space of generators of the minimal free resolution, and we shall study the resolution provided by our methods.

It is easy to check that the element \( \Delta(\Delta(a_1 \bullet a_2) \bullet a_3) \) that corresponds to the leading term of the only contributing S-polynomial will be killed by the differential of the element \( \Delta^2(a_1 \bullet (a_2 \bullet a_3)) \) (covered by corresponding overlapping leading terms \( \Delta^2(a_1) \) and \( \Delta(a_1 \bullet (a_2 \bullet a_3)) \)) in the deformed resolution. This observation goes much further, namely we have for \( k \geq 1 \)

\[
D(\Delta^k(\Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \lambda_3) \bullet \ldots) \bullet (\lambda_n \bullet a_j)) = \\
= \Delta^{k-1}(\Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \lambda_3) \bullet \ldots) \bullet \lambda_n) \bullet a_j) + \text{lower terms}
\]

in the sense of the partial ordering we discussed earlier. So, if we retain only leading terms of the differential, the resulting homology classes are represented by all the monomials of arity \( m \)

\[ \Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \ldots) \bullet \lambda_n) \]
with \( \lambda_n \) having at least two leaves. They all have the same homological degree \( m - 2 \) in the resolution (that is, formed by overlapping \( m - 2 \) leading terms), and so there are no further cancellations.

□

So far we have not been able to describe a minimal resolution of the operad \( BV \) by relatively compact closed formulas, even though in principle our proof, once processed by a version of Brown’s machinery \([8, 10]\), would clearly yield such a resolution (in the shuffle category).

5.4.3 The gravity operad and the Quillen homology of \( BV \)

The gravity operad \( \text{Grav} \) and its Koszul dual \( \text{Hycom} \) were originally defined in terms of moduli spaces of curves of genus 0 with marked points \( \mathcal{M}_{0,n+1} \) \([25, 27]\). However, we are interested in the algebraic aspects of the story, and we use the following descriptions of the gravity operad as a quadratic algebraic operad \([25]\).

An algebra over the operad \( \text{Grav} \) is a chain complex with graded antisymmetric products

\[
[x_1, \ldots, x_n] : A^\otimes n \to A
\]

of degree \( 2 - n \), which satisfy the relations:

\[
\sum_{1 \leq i < j < k} \pm[[a_i, a_j], a_1, \ldots, a_i, \ldots, a_j, \ldots, a_k, b_1, \ldots, b_l] = \\
\begin{cases} 
[[a_1, \ldots, a_k], b_1, \ldots, b_l], & l > 0, \\
0, & l = 0, 
\end{cases}
\]

for all \( k > 2, l \geq 0, \) and \( a_1, \ldots, a_k, b_1, \ldots, b_l \in A \). For example, setting \( k = 3 \) and \( l = 0 \), we obtain the Jacobi relation for \([a, b]\).

Let us define an admissible ordering of the free operad whose quotient is \( \text{Grav} \) as follows. We introduce an additional weight grading, putting the weight of the corolla corresponding to the binary bracket equal to 0, all other weights of corollas equal to 1, and extending it to compositions by additivity of weight. To compare two monomials, we first compare their weights, then the root corollas, and then path sequences \([13]\) according to the reverse path-lexicographic order. For both of the latter steps, we need an ordering of corollas; we assume that corollas of larger arity are smaller. Then for the relation \((k, l)\) in (4) (written in the shuffle notation with variables in the proper order), its leading monomial is equal to the monomial in the right hand side for \( l > 0 \), and to the monomial \([a_1, \ldots, a_{n-2}, [a_{n-1}, a_n]]\) for \( l = 0 \).

The following theorem, together with the PBW criterion, implies that the operads \( \text{Grav} \) and \( \text{Hycom} \) are Koszul, the fact first proved by Getzler \([24]\).

**Theorem 5.16.** For our ordering, the relations of \( \text{Grav} \) form a Gröbner basis of relations.
Proof. The tree monomials that are not divisible by leading terms of relations are precisely

\[ [\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, a_j], \]

where all \( \lambda_i, 1 \leq i \leq (n - 1) \) are left combs as in (2) (but made from brackets, not products).

Lemma 5.17. The graded character of the space of such elements of arity \( n \) is

\[ (2 + t^{-1})(3 + t^{-1}) \cdots (n - 1 + t^{-1}). \]

Proof. To compute the number of basis elements where the top degree corolla is of arity \( k + 1 \) (or, equivalently, degree \( 1 - k \)), \( k \geq 1 \), let us notice that this number is equal to the number of basis elements \( [\lambda_1, \lambda_2, \ldots, \lambda_k] \) where the arity of \( \lambda_k \) is at least 2 (a simple bijection: join \( \lambda_{n-1} \) and \( a_j \) into \( [\lambda_{n-1}, a_j] \)). The latter number is equal to

\[
\sum_{m_1 + \cdots + m_k = n, \quad m_i \geq 1, m_k \geq 2} \frac{(m_1 - 1)! \cdots (m_k - 1)! m_1 m_2 \cdots m_k}{(m_1 + m_2 + \cdots + m_k)(m_2 + \cdots + m_k) \cdots (m_1, m_2, \ldots, m_k)}
\]

where each factor \( (m_i - 1)! \) counts the number of left combs of arity \( m_i \), and the remaining factor is known [15] to be equal to the number of shuffle permutations of the type \( (m_1, \ldots, m_k) \). This can be rewritten in the form

\[
\sum_{m_1 + \cdots + m_k = n, m_i \geq 1, m_k \geq 2} \frac{(m_1 + \cdots + m_k - 1)!}{(m_2 + \cdots + m_k)(m_3 + \cdots + m_k) \cdots m_k}
\]

and if we introduce new variables \( p_i = m_i + \cdots + m_k \) it takes the form

\[
\sum_{2 \leq p_1 < \cdots < p_k \leq n-1} \frac{(n - 1)!}{p_2 \cdots p_k}
\]

which clearly is the coefficient of \( t^{1-k} \) in the product

\[
(n - 1)! \left( 1 + \frac{1}{2t} \right) \left( 1 + \frac{1}{3t} \right) \cdots \left( 1 + \frac{1}{(n-1)t} \right) = \]

\[
= (2 + t^{-1})(3 + t^{-1}) \cdots (n - 1 + t^{-1}).
\]

Since the graded character of Grav is given by the same formula [25], we indeed see that the leading terms of defining relations give an upper bound on dimensions of homogeneous components of Grav that coincides with the actual dimensions, so there is no room for further Gröbner basis elements. \( \square \)
Using the basis of Grav we just constructed, we are able to prove the following result (which gets a conceptual explanation in the next section):

**Theorem 5.18.** On the level of collections of graded vector spaces, we have

\[ sH^Q(BV) \cong \text{Grav}^* \otimes \text{End}_{s \mathbb{C}^{s-1}} \oplus \delta[s][\delta], \]  

(5)

where Grav* is the co-operad dual to Grav, End_{s \mathbb{C}^{s-1}} is the endomorphism operad of the graded vector space \( s \mathbb{C}^{s-1} \), and \( \delta[s][\delta] \) is a cofree coalgebra generated by an element \( \delta \) of degree 2.

**Proof.** As above, instead of looking at the bar complex, we shall study the basis of the space of generators of the minimal resolution obtained in Theorem 5.15. In arity 1, the element \( \delta^k \) (of degree 2k) corresponds to \( s \Delta^k(a_1) \) (of degree \( k + (k-1) + 1 = 2k \)), the first summand coming from the fact that \( \Delta \) is of degree 1, the second from the fact that \( \Delta^k \) is an overlap of \( k-1 \) relations, and the last one is the degree shift given by \( s \). The case of elements of internal degree 0 (which in both cases are left combs) is also obvious; a left comb of arity \( n \) in the space of generators of the free resolution is of homological degree \( n - 2 + 1 = n - 1 \), the second summand coming from the degree shift given by \( s \), and this matches the degree shift given by \( \text{End}_{s \mathbb{C}^{s-1}}(n) \). For elements of internal degree \( k - 1 \), let us extract from a typical monomial

\[ T = \Delta(\ldots \Delta(\Delta(\lambda_1 \bullet \lambda_2) \bullet \cdots) \bullet (\lambda_k \bullet a_j)), \]

of this degree and of arity \( n \) the left combs \( \lambda_1, \lambda_2, \ldots, \lambda_{k-1}, \lambda_k, a_j \), and assign to \( T \) the element of \( \text{Grav}^* \otimes \text{End}_{s \mathbb{C}^{s-1}} \) corresponding, via the degree shift, to the element dual to the monomial \( [\lambda_1, \lambda_2, \ldots, \lambda_{k-1}, \lambda_k, a_j] \in \text{Grav} \). This establishes a degree-preserving bijection, because if arities of \( \lambda_1, \ldots, \lambda_k \) are \( n_1, \ldots, n_k \), the total (internal plus homological) degree of the former element is

\[ (k - 1) + (k - 2 + 1 + (n_1 - 1) + \cdots + (n_k - 1)) + 1 = n + k - 2, \]

(where we add up the \( \Delta \) degree, the overlap degree, and the degree shift), and the total degree of the latter one is \( (k - 1) + (n - 1) = n + k - 2 \). \( \square \)

5.4.4 Relationship to Frobenius manifold construction of Baranikov and Kontsevich

We conclude with a brief discussion on how our results match those of Baranikov and Kontsevich ([5], see also [43, 45]) who proved in a rather indirect way that for a dg BV-algebra that satisfies the "\( \partial - \overline{\partial} \)-lemma", there exists a Hycom-algebra structure on its cohomology. Their result hints that our isomorphism (5) exists not just on the level of graded vector spaces, but rather has some deep operadic structure behind it. For precise statements and more details we refer the reader to [17, 34]; the point we are trying to make here is that
From Theorem 5.16, it follows that the operads Grav and Hycom are Koszul, so the cobar construction $\Omega(\text{Grav}^* \otimes \text{End}_{d[1]})$ is a minimal model for Hycom. We shall now show that the differential of $BV^\infty$ on generators coming from Grav deforms the differential of Hycom in a certain sense. Let $D$ and $d$ denote the differentials of $BV^\infty$ and Hycom respectively. We can decompose $D = D_2 + D_3 + \cdots$ according to the homotopy co-operad structure it provides on the space of generators (note that $d = d_2$ since the operad Hycom is Koszul). Also, let $m^*$ denote the obvious coalgebra structure on $\delta / \text{CZ}[\delta]$. We shall call a tree monomial in $BV^\infty$ mixed, if it contains both corollas from Grav $^* \otimes \text{End}_{d[1]}$ and from $(\delta / \text{CZ}[\delta])$. Then $D_2 = d_2 + m^*$, while for $k \geq 3$ the co-operation $D_k$ is zero on the generators $\delta / \text{CZ}[\delta]$, and maps generators from Grav into linear combinations of mixed tree monomials. Indeed, Hycom-algebras are closely related to formal Frobenius manifolds, and the result of Barannikov and Kontsevich [5] essentially implies that there exists a mapping from Hycom to the homotopy quotient $BV / \Delta$. In fact, it is an isomorphism, which can be proved in several different ways, both using Gröbner bases and geometrically; see [46] for a short geometric argument proving that. This means that the following maps exist (the vertical arrows are quasiisomorphisms between the operads and their minimal models):

$$
\begin{array}{ccc}
BV^\infty & \xrightarrow{\pi} & \text{Hycom}^\infty \\
\downarrow & & \downarrow \\
BV & \xrightarrow{\pi} & \text{Hycom} \\
\text{BV} / \Delta & \xleftarrow{\sim} & \text{Hycom}
\end{array}
$$

Lifting $\pi$: $BV^\infty \to BV / \Delta \cong \text{Hycom}$ to the minimal model $\text{Hycom}^\infty$ of Hycom, we obtain the commutative diagram

$$
\begin{array}{ccc}
BV^\infty & \xrightarrow{\psi} & \text{Hycom}^\infty \\
\downarrow & & \downarrow \\
BV & \xrightarrow{\pi} & \text{Hycom} \\
\text{BV} / \Delta & \xleftarrow{\sim} & \text{Hycom}
\end{array}
$$

so there exists a map of dg operads (and not just graded vector spaces, as it follows from our previous computations) between $BV^\infty$ and $\text{Hycom}^\infty$. Commutativity of our diagram together with simple degree considerations yields what we need.

AN EQUIVARIANT MAIN CONJECTURE IN IWASAWA THEORY
AND THE COATES-SINNOTT CONJECTURE

REZA TALEB

Received: December 12, 2012
Revised: April 4, 2013
Communicated by Otmar Venjakob

Abstract. We formulate and prove an Equivariant Main Conjecture (EMC) for all prime numbers $p$ under the assumptions $\mu = 0$ and the validity of the 2-adic Main Conjecture in Iwasawa theory [47]. This equivariant version coincides with the version, which Ritter and Weiss formulated and proved for odd $p$ under the assumption $\mu = 0$ in [35]. Our proof combines the approach of Ritter and Weiss with ideas and techniques used by Greither and Popescu in [15] in a recent proof of an equivalent formulation of the above EMC under the same assumptions ($p$ odd and $\mu = 0$) as in [35]. As an application of the EMC we prove the Coates-Sinnott Conjecture, again assuming $\mu = 0$ and the 2-adic Main Conjecture.

1 Introduction

One of the most fascinating discoveries in Arithmetic Algebraic Geometry is the still mysterious relationship between certain algebraic and analytic data attached to a given arithmetic object. Classical examples include the Conjecture of Birch and Swinnerton-Dyer, which conjecturally relates the order of vanishing of the $L$-function attached to an elliptic curve at 1 to the rank of the algebraically defined Mordell-Weil group of the curve, and Dirichlets Analytic Class Number Formula, which gives a precise algebraic interpretation of the residue of the zeta-function of a number field at 1. This last connection has been generalised to yield interpretations of special values of zeta-functions at arbitrary negative integers in terms of algebraic $K$-theory and motivic cohomology. One of the main tool to understand the deep relations between algebraic and analytic objects is Iwasawa Theory. In this theory a precise formulation of such a relationship is called the Main Conjecture. We first recall the formulation of the Main Conjecture in Iwasawa theory in the classical form:

Let $p$ be a prime number, let $F$ be a totally real number field, and let $\psi$ be a 1-dimensional $p$-adic Artin character for $F$ with $F_\psi$ totally real, where $F_\psi$ denotes the fixed field of the kernel of $\psi$. Let $F_\infty$ denote the cyclotomic $\mathbb{Z}_p$-extension of $F$. We recall Greenberg’s terminology about the different types of the characters $\psi$: $\psi$ is of type S, if $F_\psi \cap F_\infty = F$, and $\psi$ is of type W, if $F_\psi \subseteq F_\infty$. Let $O_\psi$ denote the ring obtained by adjoining all $\psi$-values to the ring $\mathbb{Z}_p$. Let $F_\psi, \infty$ be the cyclotomic $\mathbb{Z}_p$-extension of $F_\psi$ with Galois group $\Gamma$ over $F_\psi$. Throughout we fix a topological generator $\gamma$ of $\Gamma$. We denote by $S$ a finite set of primes of $F$ containing the set $S_p$ of primes above $p$ and the set of the infinite primes, and by $S_f$ the set of finite primes in $S$. Deligne and Ribet [8] and independently Cassou-Nogués [4] showed the existence of a $p$-adic $L$-function for the character $\psi$, which is continuous for $s \in \mathbb{Z}_p \setminus \{1\}$, and even at $s = 1$, if $\psi$ is not trivial. This satisfies the following interpolation property for any integer $n \geq 1$:

$$L_p(1 - n, \psi) = L(1 - n, \psi \omega^{-n}) \prod_{p \in S_p} (1 - \psi \omega^{-n}(p)Nm(p)^{1-n}).$$

Here $L(1 - n, \psi \omega^{-n})$ is the usual Artin $L$-function with respect to the character $\psi \omega^{-n}$, where $\omega : F(\mu_{2p}) \to \mathbb{Z}_p^\times$ is the Teichmüller character. Let $H_\psi \in O_\psi[T]$ be defined as $\psi(\gamma)(T + 1) - 1$ if $\psi$ is of type W, and 1 otherwise. Deligne and Ribet showed that there exists a power series $G_{\psi, S}(T) \in O_\psi[[T]]$ so that

$$L_p^S(1 - s, \psi) = \frac{G_{\psi, S}(\kappa(\gamma)^s - 1)}{H_\psi(\kappa(\gamma)^s - 1)},$$

(1.1)

**Documenta Mathematica** 18 (2013) 749–783
where $L^S_p(1 - s, \psi)$ denotes the $p$-adic $L$-function with Euler factors removed at the primes in $S$, and $\kappa$ is the restriction of the cyclotomic character to $\Gamma$. By the Weierstrass Preparation Theorem (cf. §7.1 in [16]) we have the following decomposition:

$$G_{\psi,S}(T) = \pi^u(G_{\psi,S}) g^*_{\psi,S}(T) u_{\psi,S}(T),$$

where $g^*_{\psi,S}(T)$ is a distinguished polynomial in $O_\psi[T]$, and $u_{\psi,S}(T)$ is a unit power series in $O_\psi[[T]]$. This power series represents the analytic object in the Main Conjecture.

For the cyclotomic $\mathbb{Z}_p$-extension $F_{\psi,\infty}$ of $F_\psi$ let $M^S_{\psi,\infty}$ be the maximal abelian pro-$p$-extension of $F_{\psi,\infty}$, which is unramified outside the primes in $S$, with Galois group $\mathcal{X}^S_{\infty} := Gal(M^S_{\psi,\infty}/F_{\psi,\infty})$. The pro-$p$-group $\mathcal{X}^S_{\infty}$ is equipped with a (torsion) $O_\psi[[T]]$-module structure, as well as a $Gal(F_{\psi}/F)$-action given by inner automorphisms. Serre showed that the completed group ring $O_\psi[[T]]$ can be identified with the one variable power series $O_\psi[[T]]$, by mapping $\gamma - 1$ to $T$. By the Structure Theorem of Iwasawa theory (cf. §13.2 in [46]) for $O_\psi[[T]]$-modules, the $\psi$-eigenspace

$$\mathcal{X}^S_{\infty} := \{ x \in \mathcal{X}^S_{\infty} \otimes_{\mathbb{Z}_p} O_\psi | \sigma(x) = \psi(\sigma)x \text{ for all } \sigma \in Gal(F_{\psi}/F) \}$$

of $\mathcal{X}^S_{\infty}$ is pseudo-isomorphic, as an $O_\psi[[T]]$-module, to a unique $O_\psi[[T]]$-module of the form

$$\bigoplus_{i=1}^m O_\psi[[T]]/p_1^{n_1}$$

for $m \geq 1$ and $n_i \geq 1$. Here $p_i$ is the ideal generated by either a fixed uniformizer $\pi \in O_\psi$ or a monic irreducible polynomial in $O_\psi[T]$. We call the ideal $\prod_{i=1}^m p_i^{n_i}$ the characteristic ideal. By the Weierstrass Preparation Theorem (cf. §7.1 in [16]) we can choose a unique generator for the characteristic ideal of the following form

$$F_{\psi,S}(T) = \pi^u(F_{\psi,S}) f^*_{\psi,S}(T),$$

where $f^*_{\psi,S}(T)$ is a distinguished polynomial in $O_\psi[T]$. The polynomial $F_{\psi,S}(T)$ is called the characteristic polynomial of $\mathcal{X}^S_{\infty,\psi}$. The classical Main Conjecture in Iwasawa theory is formulated as follows: If the character $\psi$ is of type $S$, then

$$f^*_{\psi,S}(T) = g^*_{\psi,S}(T).$$

This was proved by Wiles in [47] for any totally real number field $F$ and an odd prime $p$. He also proved the conjecture for the prime 2 and the character $\psi$ provided $F_\psi$ is an abelian extension of $\mathbb{Q}$. He also showed the equality of the $\mu$-invariants $\mu(F_{\psi,S}) = \mu(G_{\psi,S})$ for odd primes $p$ and characters $\psi$. For odd primes $p$, both invariants $\mu(F_{\psi,S})$ and $\mu(G_{\psi,S})$ are known to be zero in the case $F_{\psi}/\mathbb{Q}$ is abelian (cf. [10]), and are conjectured to be zero in general.

The $O_\psi[[T]]$-torsion module $\mathcal{X}^S_{\infty,\psi}$ is of projective dimension at most one and has a principal Fitting ideal generated by the characteristic polynomial.
If we denote by \( G \) the set of primes of \( F \), and let \( \mathbb{Z} \) be the filed of totally real number fields, the Main Conjecture gives an equality of ideals over the power series ring \( \mathbb{O}_E[[T]] \). As we see, for any character \( \psi \) of \( G \), the Galois group of the abelian \( p \)-extension of \( \mathbb{Z}_p \), unramified outside the primes in \( S_f \), over \( \mathbb{F}_\psi,\infty \). For an odd prime \( p \) the two \( \mathbb{O}_E[[T]] \)-modules are the same, since \( \psi \)_primes are unramified in \( p \)-extensions for \( p \) odd. However, for \( p = 2 \) the two modules are related by Lemma 5.9, which shows that they may differ in their \( \mu \)-invariants. If we assume that \( X_{\infty}^f \) has trivial \( \mu \)-invariant, then the analogous formulation of the Main Conjecture in terms of ideals for the prime \( 2 \) reads as follows:

\[
Fitt_{\mathbb{O}_E[[T]]}(X_{\infty}^{S_f}) = (G_{\psi,S}(T)).
\]

To obtain a similar formulation of the Main Conjecture in terms of ideals for the prime \( 2 \), we replace \( X_{\infty}^f \) by \( X_{\infty}^f \), where \( X_{\infty}^f := X_{\infty}^{S_f} \) is the Galois group of the maximal abelian \( p \)-extension of \( \mathbb{F}_\psi,\infty \). In this article the assumption \( \mu = 0 \) refers to the following assumption:

\[
\mu = 0 : \quad \text{The } \mu \text{-invariant of } X_{\infty}^f := X_{\infty}^{S_f} \text{ is zero, i.e. the } \mathbb{Z}_p \text{-module } X_{\infty}^f \text{ is finitely generated.}
\]

We note that \( X_{\infty}^f \) maps by Galois restriction to the Galois group \( \text{Gal}(M_{\psi,\infty}^{S_f}/\mathbb{F}_\psi,\infty) \), where \( M_{\psi,\infty}^{S_f} \) is the maximal abelian \( p \)-extension of \( \mathbb{F}_\psi,\infty \) unramified outside the primes in \( S_f \), with a finite cokernel for any character \( \psi \) of \( G \). Here the cokernel is \( \text{Gal}(\mathbb{F}_\infty \cap M_{\psi,\infty}^{S_f}/\mathbb{F}_\psi) \), which is a
quotient of a subgroup of $H$, and whence finite. As a result the assumption 
$\mu = 0$ implies that the $\mu$-invariant of $Gal(M^{S_f}_{\psi, \infty}/F_{\psi, \infty})$ is zero, and therefore the $\mu$-invariant of $X^{\psi}_{\infty}$ vanishes for any (even) character $\psi$ of $G$.

The pro-$p$ group $X_{\infty}$ has a (torsion) $A$-module structure, whose projective dimension is not necessarily at most one. However to formulate an Equivariant Main Conjecture, similar to the classical Main Conjecture, one needs a finitely generated $A$-torsion module of projective dimension at most one. Let $d_{\infty}$ be a non-zero divisor of the augmentation ideal $\Delta G_{\infty}$ of $A$, let $c_{\infty}$ be an invertible element of the total ring of fraction of $A$, so that $d_{\infty} = c_{\infty}((\gamma - 1)e + (1 - e))$, where $e$ is the idempotent attached to the trivial character of $H$. We denote by $L$ the fixed field of $E/F$ under the action of the $p$-Sylow subgroup of $G$, by $G$ the Galois group of the maximal algebraic extension $\Omega^S_L$ of $L$ unramified outside the primes in $S$, over $F$, and by $H$ the Galois group of $\Omega^S_L/E_{\infty}$. There is a commutative diagram of $A$-modules

\[
\begin{array}{cccccc}
0 & 0 & 0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
X_{\infty} & Y_{\infty} & \Delta G_{\infty} & 0 & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
Z_{\infty} & z_{\infty} & 0 & 0 & 0 \\
\end{array}
\]

where $\psi$ maps 1 to $d_{\infty}$, $\Psi$ maps 1 to a pre-image $y_{\infty}$ of $d_{\infty}$, and $Y_{\infty} = H_{\infty}(H, \Delta G)$. Here $\Delta G$ denotes the augmentation ideal of $\mathbb{Z}_p[[G]]$. We will see that this definition of $Y_{\infty}$ is the same as the definition of Ritter-Weiss in [35]. The $A$-torsion module $Z_{\infty}$ in the diagram above, whose projective dimension is at most one, shows up as the algebraic object in the Equivariant Main Conjecture of Ritter-Weiss. We note that the construction of $Z_{\infty}$ depends on the choice of $d_{\infty}$. Before stating the algebraic object we remark that there exists a subgroup $\Gamma \leq G_{\infty}$, topologically generated by $\gamma$, so that $G_{\infty} = H \times \Gamma$ for the abelian group $G_{\infty}$. The analytic object is defined as follows:

$$G_S := \sum_{\psi \in H} G_{\psi, \psi}(\gamma - 1) \cdot e_\psi \in \frac{1}{|H|} O[H][[\Gamma]],$$

where $e_\psi$ is the idempotent attached to the character $\psi$ of $H$, i.e.

$$e_\psi := \frac{1}{|H|} \sum_{\sigma \in G} \psi(\sigma)\sigma^{-1}.$$

One version of the Equivariant Main Conjecture of Ritter-Weiss [35] for odd primes is as follows (cf. [28], §2, (CPE2)):

$$Fitt_A(Z_{\infty}) = (c_{\infty}G_S),$$

Documenta Mathematica 18 (2013) 749–783
which was verified under the assumption of the vanishing of the $\mu$-invariant of $X_\infty$, i.e. assuming that $X_\infty$ is a finitely generated $\mathbb{Z}_p$-module. It is worth mentioning that they have generalized and proved their Equivariant Main Conjecture in the non-commutative case, still assuming the vanishing of the $\mu$-invariant of a certain Iwasawa module (see [36]). In [15], Greither and Popescu have recently formulated and proved an Equivariant Main Conjecture in Iwasawa theory in the abelian case in terms of the Tate module of a certain Iwasawa-theoretic abstract 1-motive again under the assumptions $\mu = 0$ and $p$ odd. More recently, Nickel [29] showed that this formulation is equivalent to the formulation of Ritter-Weiss.

We now describe our Equivariant Main Conjecture for an arbitrary prime $p$. For an abelian extension $E/F$, by applying the algebraic construction of the Equivariant Main Conjecture of Ritter-Weiss to the set $S_f$ of finite primes in $S$, we construct the $A$-torsion module $Z_{f,\infty}$, which is of projective dimension at most one. We show that it satisfies the following exact sequence:

$$0 \to \mathbb{Z}_p \to (A/d_\infty A)^\# \to \alpha(Z_{f,\infty}) \to \alpha(X_{f,\infty}) \to 0,$$

in which $pd_A((A/d_\infty A)^\#) \leq 1$ and $pd_A(\alpha(Z_{f,\infty})) \leq 1$.

Here $\alpha$ is the adjoint functor in Iwasawa theory with the contravariant action and $M^\#$, for any $A$-module $M$, denotes the same underlying module but with $g$ acting as $g^{-1}$ for any $g \in G_\infty$. The Equivariant Main Conjecture is then formulated as follows (cf. Conjecture 4.1):

$$Fitt_A(Z_{f,\infty}) = (c_\infty G_S^*),$$

where

$$G_S^* := \sum_{\psi \in H} G_{\psi,S}^*(\gamma - 1) \cdot e_\psi \in \frac{1}{|H|} \mathcal{O}[H][[\Gamma]].$$

Here we recall that $G_{\psi,S}^*(T) = g_{\psi,S}(T)u_{\psi,S}(T)$. In Section 4, we prove that this conjecture follows from the classical Main Conjecture under the assumption $\mu = 0$ by taking advantage of the idea of determinantal ideals used by Greither and Popescu [15].

In the last section we show that the Coates-Sinnott Conjecture follows from the Equivariant Main Conjecture assuming $\mu = 0$ (cf. Theorem 5.10). After some fundamental work of Coates-Sinnott in [6] and more recent results by Ritter-Weiss, Nguyen Quang Do, Burns-Greither, Greither-Popescu et al. the Coates-Sinnott Conjecture is completely known up to powers of 2, assuming $\mu = 0$. However, the 2-primary information was neglected more or less completely due to various technical problems. For example, there was no formulation of an Equivariant Main Conjecture in Iwasawa theory for the prime 2 at the time.
An Equivariant Main Conjecture

The Coates-Sinnott Conjecture is a generalization of the classical Stickelberger Theorem, which provides elements annihilating the class group of a cyclotomic field, using special values of analytic functions. To make it more precise, let $E/F$ be an abelian extension with Galois group $G$, and let $S$ be a finite set of primes in $F$ containing the primes ramified in $E$ and the infinite primes. Let

$$\Theta_{E/F}^S(s) := \sum_{\chi \in \hat{G}} L_{E/F}^S(s, \chi^{-1}) \cdot e_\chi \in \mathbb{C}[G]$$

be the $S$-incomplete equivariant $L$-function, where $e_\chi$ is the idempotent attached to any character $\chi$ of $G$. Deligne and Ribet [8] and independently Cassou-Noguès [4] proved that

$$\text{Ann}_{\mathbb{Z}[G]}(H^0(E, \mathbb{Q}/\mathbb{Z}(n))) \cdot \Theta_{E/F}^S(1 - n) \subseteq \mathbb{Z}[G]$$

for any integer $n \geq 1$. Stickelberger’s Theorem shows that the following analytic object is in the annihilator ideal of the class group $\text{Cl}(\mathcal{O}_E)$ of the field $E$ in the case $F = \mathbb{Q}$:

$$\text{Ann}_{\mathbb{Z}[G]}(H^0(E, \mathbb{Q}/\mathbb{Z}(1))) \cdot \Theta_{E/F}^S(0) \subseteq \text{Ann}_{\mathbb{Z}[G]}(\text{Cl}(\mathcal{O}_E)).$$

This setup has been generalized in two directions: First of all one looks at an arbitrary relative abelian extension $E/F$ of number fields. Here the analogue of Stickelberger’s theorem (Brumer’s Conjecture) is still not completely known. In a different direction one replaces the class group by algebraic $K$-groups or motivic cohomology groups and studies annihilators of these groups as Galois modules for relative abelian extensions. In [6], Coates and Sinnott formulated the relevant conjecture in terms of higher Quillen $K$-groups as

$$\text{Ann}_{\mathbb{Z}[G]}(H^0(E, \mathbb{Q}/\mathbb{Z}(n))) \cdot \Theta_{E/F}^S(1 - n) \subseteq \text{Ann}_{\mathbb{Z}[G]}(K_{2n - 2}(\mathcal{O}_E))$$

for any integer $n \geq 2$. As a result of the recent work of Voevodsky in [45] the relation between algebraic $K$-theory, étale cohomology for all prime numbers and motivic cohomology is known. This yields the motivic formulation of the Coates-Sinnott Conjecture, which implies the $K$-theoretic version. Moreover, it enables us to study each $p$-primary part of the conjecture separately for any prime number $p$ as follows:

$$\text{Ann}_{\mathbb{Z}_p[G]}(H^0(E, \mathbb{Q}_p/\mathbb{Z}_p(n))) \cdot \Theta_{E/F}^S(1 - n) \subseteq \text{Ann}_{\mathbb{Z}_p[G]}(H_{\text{ét}}^2(\mathcal{O}_E', \mathbb{Z}_p(n)))$$

for any integer $n \geq 2$, where $H_{\text{ét}}^2(\mathcal{O}_E', \mathbb{Z}_p(n)) = \lim_{\rightarrow m} H_{\text{ét}}^2(\mathcal{O}_E', \mu_p^m)$ and $H_{\text{ét}}^2(\mathcal{O}_E', \mu_p^m)$ refers to the étale cohomology of the scheme $\text{Spec}(\mathcal{O}_E[1/p])$ with values in the étale sheaf $\mu_p^m$. In the last section we complete the proof of the Coates-Sinnott Conjecture under the assumption $\mu = 0$ by proving it for the prime 2.
Acknowledgement. The material in this article forms a part of the author’s Ph.D. thesis [43] at McMaster university. The author would like to express his gratitude to his Ph.D. supervisor Manfred Kolster for introducing these subjects, for his encouragement and helpful discussions and suggestions. The author would also like to thank the referee for his detailed comments and suggestions.

2 Algebraic Construction

Let $E/F$ be a finite abelian extension of totally real number fields with Galois group $G$, and let $p$ be an arbitrary prime. Let $E_\infty$ (resp. $F_\infty$) be the cyclotomic $\mathbb{Z}_p$-extension of $E$ (resp. $F$). We denote the multiplicative group $\text{Gal}(E_\infty/E)$ (resp. $\text{Gal}(F_\infty/F)$) by $\Gamma_E$ (resp. $\Gamma_F$). Let $H$ denote the Galois group of the finite abelian extension $E_\infty/F_\infty$. We denote by $G_\infty := \text{Gal}(E_\infty/F)$ the Galois group of the abelian extension $E_\infty/F$. We let $S$ denote a finite set of primes of $F$ which ramify in $E_\infty$, and the infinite primes. In particular $S$ contains the set $S_p$ of the primes above $p$. The set of finite primes in $S$ is also denoted by $S_f$. We use the same notations for the set of primes above the primes in $S$ and $S_f$, respectively, in any intermediate field of $E_\infty/F$. Since $\Gamma_F$ is topologically generated by one element, the exact sequence

$$0 \rightarrow H \rightarrow G_\infty \xrightarrow{\imath} \Gamma_F \rightarrow 0$$

(2.1)

splits. We denote by $\Gamma \leq G_\infty$ the image of $\Gamma_F$, so that $G_\infty \simeq H \times \Gamma$, and by $\Lambda$ the completed group ring $\mathbb{Z}_p[[\Gamma]]$. Let $E'$ be the fixed field of $E_\infty$ under the action of the closed subgroup $\Gamma$. Then $E' \cap F_\infty = F$, $E_\infty = E' \cdot F_\infty$, $\text{Gal}(E'/F) \simeq H$ and $E_\infty/E'$ is also a cyclotomic $\mathbb{Z}_p$-extension.

Let $M_\infty^S$ and $M_\infty^{S_f}$ be the maximal abelian pro-$p$-extensions of $E_\infty$ unramified outside the primes in $S$ and $S_f$, respectively. We recall that $\mathcal{X}_\infty = \mathcal{X}_\infty^S$ and $\mathcal{X}_\infty^{S_f} := \mathcal{X}_\infty^S/\mathcal{X}_\infty^{S_f}$ denote the Galois group of the extensions $M_\infty^S/E_\infty$ and $M_\infty^{S_f}/E_\infty$, respectively. Since $E$ is totally real, the $\Lambda$-module $\mathcal{X}_\infty$ is a torsion module with no non-trivial finite submodule by Propositions 10.3.22 and 10.2.25 in [31]. The $\Lambda$-module $\mathcal{X}_\infty^{S_f}$, which is a quotient of $\mathcal{X}_\infty$, is also torsion and has no non-trivial finite submodule (cf. [38], §6.4). Finally, we set $\mathcal{A} := \mathbb{Z}_p[[G_\infty]]$ and we freely use the identification

$$\mathcal{A} \simeq \mathbb{Z}_p[H][[T]],$$

(2.2)

which is given by mapping the topological generator $\gamma$ of $\Gamma$ to $1 + T$.

Remark 2.1. For an odd prime $p$, infinite primes of $F$ are unramified in a pro-$p$-extension. Hence $M_\infty^S$ and $M_\infty^{S_f}$ coincide and therefore, $\mathcal{X}_\infty = \mathcal{X}_\infty^{S_f}$ for odd primes.
The following diagram illustrates the situation:

We recall that the Main Conjecture in Iwasawa theory for a character \( \psi \) of \( G \) can be written in the form (1.2), assuming \( \mu = 0 \). Here the Fitting ideal of the (finitely generated) \( \mathcal{O}_\psi[[T]] \)-torsion module \( \mathcal{X}^I,\psi \) is principal, because it has projective dimension at most one, and is generated by the \( p \)-adic \( L \)-function associated to \( \psi \). Hence to formulate an Equivariant Main Conjecture we construct an appropriate (finitely generated) \( \mathcal{H} \)-torsion module of projective dimension at most one. The resulting Fitting ideal is then principal, and conjecturally generated by an equivariant \( p \)-adic \( L \)-function. This was done by Ritter-Weiss for odd primes in [35]. The strategy of this part is as follows: Since the \( \mathcal{H} \)-torsion module \( \mathcal{X}_f \) is not necessarily of projective dimension at most one, we first construct an \( \mathcal{H} \)-module \( \mathcal{Y}_f \) of projective dimension at most one. Since this module is not necessarily \( \mathcal{H} \)-torsion, we pass to a quotient \( \mathcal{Z}_f \), which is then shown to be a (finitely generated) \( \mathcal{H} \)-torsion module of projective dimension at most one, whose principal Fitting ideal is conjecturally generated by an equivariant \( L \)-function.

Let \( P \) be the \( p \)-Sylow subgroup of \( G \) and let \( L \) be the fixed field of \( E \) under the action of \( P \) with Galois group \( Q \) over \( F \). Let \( \Omega^{S_f}_L \) be the maximal algebraic pro-\( p \)-extension of \( L \), which is unramified outside the primes in \( S_f \). We denote by \( \mathcal{H} \) the Galois group of \( \Omega^{S_f}_L \) over \( E_\infty \), and by \( \mathcal{G} \) the Galois group of \( \Omega^{S_f}_L \) over \( F \). The finitely generated group \( \mathcal{G} \) has a presentation of the form \( \mathcal{G} \simeq \mathcal{F}/\mathcal{W} \), where \( \mathcal{F} \) is an appropriate free profinite group of rank \( d \) and \( \mathcal{W} \) is a relation subgroup of \( \mathcal{F} \) of rank \( r \). For a certain relation subgroup \( \mathcal{R} \) of \( \mathcal{F} \) we then have an isomorphism \( \mathcal{G}_\infty \simeq \mathcal{F}/\mathcal{R} \). The following diagram illustrates the situation:
We apply Proposition 5.6.7 in [31] (see also Lemma 4.3 in [17]) to the profinite groups in the commutative diagram

\[
\begin{array}{ccc}
1 & 1 \\
\uparrow & \uparrow \\
W & = & W \\
\downarrow & \downarrow \\
1 & \to & R \\
\downarrow & \downarrow \\
1 & \to & H \\
\downarrow & \downarrow \\
1 & \to & G & \to & G_{\infty} & \to & 1 \\
\end{array}
\]

and obtain a commutative diagram:

\[
\begin{array}{cccccc}
0 & 0 \\
\downarrow & \downarrow \\
0 & \to & H_2(H, \mathbb{Z}_p) & \to & H_0(H, \mathcal{W}_{ab}) & \to & \mathcal{R}_{ab}(p) & \to & X_{\infty}^f & \to & 0 \\
\| & \| & \downarrow & \downarrow \\
0 & \to & H_2(H, \mathbb{Z}_p) & \to & H_0(H, \mathcal{W}_{ab}) & \to & \mathfrak{A}_d & \to & Y_{\infty}^f & \to & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
\Delta G_{\infty} & = & \Delta G_{\infty} \\
0 & 0,
\end{array}
\]

(2.3)

where $\Delta G_{\infty}$ denotes the augmentation ideal of $A$. Here $Y_{\infty}^f := H_0(H, \Delta \mathcal{G})$ and $\Delta \mathcal{G}$ and $\Delta G_{\infty}$ denote the augmentation ideals of $\mathcal{G}$ and $G_{\infty}$, respectively.

**Remark 2.2.** The same construction leads to a similar diagram for an arbitrary intermediate field of $\Omega_S^f/L$.

Since the cyclotomic $\mathbb{Z}_p$-extension $E_{\infty}/E$ satisfies the weak Leopoldt Conjecture by Proposition 10.3.25 in [31], the group $H_2(H, \mathbb{Z}_p)$ in diagram (2.3) vanishes (cf. Proposition 10.3.22 in [31]). Moreover we have the following proposition:

**Proposition 2.3.** The $\mathfrak{A}$-module $H_0(H, \mathcal{W}_{ab})$ is projective.

**Proof.** Since $|Q|$ is prime to $p$, we have the equality of cohomological dimensions

$$cd_p(\mathcal{G}) = cd_p(Gal(\Omega^{S_f}_L/L)).$$

The $p$-cohomological dimension of the pro-$p$ group $Gal(\Omega^{S_f}_L/L)$ is at most 2 by Proposition 8.3.17 in [31] for odd primes $p$ (note that infinite primes are unramified in any $p$-extension for $p$ odd), and by Theorem 1 in [38] for $p = 2$, i.e.

$$cd_p(\mathcal{G}) \leq 2$$

for any prime $p$. Now Proposition 5.6.7 in [31] completes the proof. \qed

**Remark 2.2.** The same construction leads to a similar diagram for an arbitrary intermediate field of $\Omega_S^f/L$. 

Since the cyclotomic $\mathbb{Z}_p$-extension $E_{\infty}/E$ satisfies the weak Leopoldt Conjecture by Proposition 10.3.25 in [31], the group $H_2(H, \mathbb{Z}_p)$ in diagram (2.3) vanishes. (cf. Proposition 10.3.22 in [31]). Moreover we have the following proposition:

**Proposition 2.3.** The $\mathfrak{A}$-module $H_0(H, \mathcal{W}_{ab})$ is projective.

**Proof.** Since $|Q|$ is prime to $p$, we have the equality of cohomological dimensions

$$cd_p(\mathcal{G}) = cd_p(Gal(\Omega^{S_f}_L/L)).$$

The $p$-cohomological dimension of the pro-$p$ group $Gal(\Omega^{S_f}_L/L)$ is at most 2 by Proposition 8.3.17 in [31] for odd primes $p$ (note that infinite primes are unramified in any $p$-extension for $p$ odd), and by Theorem 1 in [38] for $p = 2$, i.e.

$$cd_p(\mathcal{G}) \leq 2$$

for any prime $p$. Now Proposition 5.6.7 in [31] completes the proof. \qed
Let $\chi$ be a $C_p$-valued character of the group $Q$, let

$$e_\chi := \frac{1}{|Q|} \sum_{\sigma \in Q} \chi(\sigma)\sigma^{-1}$$

be the idempotent of $Q$ attached to the character $\chi$, and let $A_\chi := O_\chi[[G_\infty(p)]]$, where $O_\chi$ is the ring obtained by adjoining all character values of $\chi$ to $\mathbb{Z}_p$. Since $G_\infty(p) \simeq P \times \Gamma$ is a pro-$p$ group, $A_\chi$ is a local ring and therefore, $e_\chi H_0(H, W^ab)$ is a free $A_\chi$-module of rank $r_\chi$:

$$e_\chi H_0(H, W^ab) \simeq A_\chi^{r_\chi}. \tag{2.4}$$

Now by applying $e_\chi$ to the exact sequence in the second row of diagram (2.3) we obtain:

$$0 \to A_\chi^{r_\chi} \to A_\chi^d \to e_\chi Y_f^\infty \to 0.$$

From the last column of diagram (2.3) we have

$$0 \to e_\chi X_f^\infty \to e_\chi Y_f^\infty \to A_\chi \to e_\chi \mathbb{Z}_p \to 0.$$

This implies that $e_\chi Y_f^\infty$ has rank one and as a result $r_\chi = d - 1$ for any character $\chi$. Now by taking the direct sum over all characters of $Q$ in equality (2.4) we obtain:

$$H_0(H, W^ab) \simeq A^r$$

for $r = d - 1$. Therefore, diagram (2.3) can be rewritten as

\[
\begin{array}{cccccc}
0 & \to & A^r & \xrightarrow{f} & \mathcal{R}^{ab}(p) & \to \mathcal{X}_\infty^f & \to 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & \mathcal{A}^{r+1} & \xrightarrow{g} & \mathcal{Y}_\infty^f & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\Delta G_\infty & = & \Delta G_\infty & \to & 0 & .
\end{array}
\tag{2.5}
\]

So far we have constructed the module $Y_\infty^f$, which fits into the exact sequence

$$0 \to \mathcal{X}_\infty^f \to \mathcal{Y}_\infty^f \to \Delta G_\infty \to 0. \tag{2.6}$$

The second row in diagram (2.5) implies that the $A$-module $Y_\infty^f$ is of projective dimension at most one. To replace it by a torsion $A$-module we now take a quotient of $Y_\infty^f$ by a certain submodule as follows:

Let $d_\infty \in \Delta G_\infty$ be a non-zero divisor in the augmentation ideal of $A$ and let $c_\infty$ be an invertible element in $Q(A)$ such that

$$d_\infty = c_\infty((\gamma - 1)e + (1 - e)), \tag{2.7}$$
where \( \gamma \) is the fixed (topological) generator of \( \Gamma \leq G_\infty \) and \( e = \frac{1}{|H|} \sum_{h \in H} h \) is the idempotent of \( \mathbb{Q}_p[H] \) attached to the trivial character of \( H \). Here we note that \( \gamma - 1 \) and \( 1 - e \) generate \( \Delta G_\infty \otimes \mathbb{Q}_p \), and that \( \gamma - 1 \) and \( 1 - e \) can be written in the form (2.7) as follows:

\[
\begin{align*}
\gamma - 1 &= (e + (\gamma - 1)(1 - e))((\gamma - 1)e + (1 - e)), \\
1 - e &= (1 - e)((\gamma - 1)e + (1 - e)).
\end{align*}
\]

Let \( y_\infty \) be a pre-image of \( d_\infty \) in \( Y_\infty \) in diagram (2.5). We have the following diagram:

\[
\begin{array}{ccccccccc}
0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow \\
A & = & A \\
\downarrow \Phi & \downarrow \phi \\
0 \to X_\infty^f & \to Y_\infty^f & \to \Delta G_\infty & \to 0 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
0 \to X_\infty^f & \to Z_\infty^f & \to z_\infty^f & \to 0
\end{array}
\]

(2.8)

where \( \Phi \) and \( \phi \) are defined by mapping \( 1 \in A \) to \( y_\infty \) and to \( d_\infty \), respectively, and \( Z_\infty^f \) and \( z_\infty^f \) are the quotients of \( Y_\infty^f \) and \( \Delta G_\infty \) by the images of \( \Phi \) and \( \phi \), respectively. We note that the vertical maps are injective since \( d_\infty \in A \) is a non-zero divisor. By a diagram chase in the diagram

\[
\begin{array}{ccccccccc}
A & = & A \\
\downarrow \phi & \downarrow \phi \\
0 \to \Delta G_\infty & \to A & \to Z_p & \to 0,
\end{array}
\]

we obtain:

**Lemma 2.4.** The sequence

\[
0 \to z_\infty^f \to A/d_\infty A \to Z_p \to 0
\]

(2.9)

is exact, where the middle term is of projective dimension one and

\[
\text{Fitt}_A(A/d_\infty A) = (d_\infty).
\]

By using the middle column of diagram (2.8) and the first row of diagram (2.5) we also obtain the commutative diagram

\[
\begin{array}{ccccccccc}
0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow \\
\mathcal{A} & = & \mathcal{A} \\
\downarrow \Psi & \downarrow \phi \\
0 \to \mathcal{A}_r & \to \mathcal{A}_r+1 & \to \mathcal{A} & \to 0 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
0 \to \mathcal{R}^{ab}(p) & \to \mathcal{A}_r+1 & \to \Delta G_\infty & \to 0 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
0 \to X_\infty^f & \to Z_\infty^f & \to z_\infty^f & \to 0
\end{array}
\]

(2.10)
which implies the following proposition:

**Proposition 2.5.** $Z_f^\infty$ is a finitely generated $A$-torsion module of projective dimension at most one:

$$\text{pd}_A(Z_f^\infty) \leq 1.$$  

3 Analytic Construction

Again let $E/F$ be an abelian extension of totally real fields, let $S$ be a finite set of primes in $F$ containing the primes above $p$, the primes ramified in $E$ and the infinite primes, and let $S_f$ denote the set of finite primes in $S$. As before, we denote by $E_\infty$ and $F_\infty$ the cyclotomic $\mathbb{Z}_p$-extensions of $E$ and $F$, respectively, by $H$ the Galois group of $E_\infty/F_\infty$, and by $G_\infty \cong H \times \Gamma$ the Galois group of $E_\infty/F$. We define equivariant versions of $G_{\psi,S}$ and $H_\psi$ as follows (cf. [34], Proposition 5.4): For a character $\psi$ of $G_{\infty}$, let $G_{\psi,S}^*(T), H_\psi(T) \in \mathcal{O}_{\psi}[\![T]\!]$ be the power series defined in (1.1). Let

$$G_S := \sum_{\psi \in \hat{H}} G_{\psi,S}(\gamma - 1) \cdot e_\psi \in \left[\frac{1}{|H|}\mathcal{O}[H][[\Gamma]]\right]$$

$$H_S := \sum_{\psi \in \hat{H}} H_\psi(\gamma - 1) \cdot e_\psi \in \left[\frac{1}{|H|}\mathcal{O}[H][[\Gamma]]\right]$$

be the equivariant versions of $G_{\psi,S}$ and $H_\psi$. For any character $\chi$ of $G_{\infty}$, they satisfy the following:

$$\chi(G_S) = G_{\chi,S}(0) \quad , \quad \chi(H_S) = H_\chi(0).$$

We recall that for any character $\psi$ of $G$ one has

$$G_{\psi,S}(T) = \pi^{\mu(G_{\psi,S})} \cdot g_{\psi,S}^*(T) \cdot u_{\psi,S}(T)$$

by the Weierstrass Preparation Theorem, where $\pi$ is a fixed uniformizer in $\mathcal{O}_\psi$, $g_{\psi,S}^*(T) \in \mathcal{O}_{\psi}[\![T]\!]$ is a distinguished polynomial, and $u_{\psi,S}(T) \in \mathcal{O}_\psi[\![T]\!]$ is a unit. The modified equivariant $L$-function $G_S^*$ is now defined as follows:

$$G_S^* := \sum_{\psi \in \hat{H}} G_{\psi,S}^*(\gamma - 1) \cdot e_\psi \in \left[\frac{1}{|H|}\mathcal{O}[H][[\Gamma]]\right],$$

where $G_{\psi,S}^*(T) = g_{\psi,S}^*(T)u_{\psi,S}(T)$. The following lemma relates $G_S$ and $G_S^*$, assuming $\mu = 0$ (cf. (1.3)):

**Lemma 3.1.** Under the assumption $\mu = 0$ we have the following equalities:

Documenta Mathematica 18 (2013) 749–783
2. \( G_S = 2^{\nu_1(F)}G^*_S \) for \( p = 2 \).

Proof. Part 1 follows from the result of Wiles [47] that \( \mu(G_{\psi, S}) \) is the same as the Iwasawa \( \mu \)-invariant of \( X_{\infty}^L \psi \) for all odd primes \( p \). Part 2 follows from the fact that \( \pi \mu(G_{\psi, S}) = 2^{\nu_1(F)} \) under the assumption \( \mu = 0 \), where \( \pi \in O_\psi \) is a uniformizer, for any character \( \psi \) of \( G \) (see [12], pages 82 and 87).

We note that Lemma 3.1 holds unconditionally for abelian extensions \( E \) of \( \mathbb{Q} \), since in this case \( \mu = 0 \) (cf. [10]).

To prove the next lemma we briefly review the definition of a \( p \)-adic pseudo-measure on a certain Galois group and its relation to the \( p \)-adic \( L \)-function. For more properties one can consult [39]. For a commutative profinite group \( \mathcal{G} \), \( \lambda_S \in Q(\mathbb{Z}_p[[\mathcal{G}]]) \) is called a pseudo-measure on \( \mathcal{G} \) if \((g-1)\lambda_S \) is a measure, i.e. \((g-1)\lambda_S \in \mathbb{Z}_p[[\mathcal{G}]]\), for any \( g \in \mathcal{G} \), where \( Q(\mathbb{Z}_p[[\mathcal{G}]]) \) denotes the quotient ring of \( \mathbb{Z}_p[[\mathcal{G}]] \). Let \( \mathcal{X} \) denote the Galois group of the maximal abelian extension of \( F \) unramified outside the primes in \( S_F \) over \( F \). By a theorem of Deligne and Ribet there is a unique pseudo-measure on \( \mathcal{X} \) denoted by \( \lambda_S \in Q(\mathbb{Z}_p[[\mathcal{X}]]) \), which satisfies the following relation for any finite order character \( \chi \) of \( \mathcal{X} \):

\[
L_{p, S}(1 - s; \chi) = \langle \chi h^e, \lambda_S \rangle.
\]

For the definition of this inner product see [39]. Equivalently, if we let \( \varepsilon : \mathcal{X} \to \mathbb{Z}_p \) be the locally constant function defined by \( \varepsilon(g) = 1 \) if \( g \) has image 1 in \( H = \text{Gal}(\mathbb{E}_\infty / F_\infty) \), and zero otherwise, then

\[
\zeta_p^S(\varepsilon_h, 1 - n) = \langle \varepsilon_h h^n, \lambda_S \rangle.
\]

Here \( \rho \) is the cyclotomic character, \( \varepsilon_h \) is the locally constant function satisfying \( \varepsilon_h(x) = \varepsilon(hx) \) and \( \zeta_p^S(\varepsilon_h, s) \) is the \( S \)-incomplete \( p \)-adic partial zeta function associated to \( \varepsilon_h \). The image of \( \lambda_S \) under the natural surjection \( \pi : \mathcal{X} \to G_\infty \) is a \( p \)-adic pseudo-measure on \( G_\infty \) which is denoted by \( \theta_S \in Q(\mathbb{A}) \). So if \( \hat{\gamma} \in \mathbb{X} \) denotes a pre-image of \( \gamma \in G_\infty \) under the surjection above, then

\[
Z_S := \pi((\hat{\gamma} - 1)\lambda_S) \in \mathbb{A}.
\]

In fact \( \theta_S = (\gamma - 1)^{-1}Z_S \in Q(\mathbb{A}) \). With notations as above we have the following lemma:

**Lemma 3.2.** Let \( d_\infty \) be a non-zero divisor in the augmentation ideal \( \Delta G_\infty \), and let \( c_\infty \) be an invertible element in \( Q(\mathbb{A}) \) so that \( d_\infty = c_\infty((\gamma - 1)e + (1 - e)) \in \Delta G_\infty \), where \( e \) is the idempotent associated to the trivial character of \( H \). Then

\[
c_\infty G_S = d_\infty \theta_S \in \mathbb{A}.
\]

Proof. A calculation in Proposition 12 in [35], which works for any character \( \chi \) of \( G_\infty \) satisfying \( \chi(\gamma) = 1 \) and for any prime \( p \), provides the following equality:

\[
\frac{G_{\chi, S}(T)}{T^{\chi(1)}} = \sum_{h \in H} \chi(h) \frac{Z_S(h, T)}{T}
\]
Here $Z_S(h, T)$ is given by the relation $Z_S = \sum_{h \in H} Z_S(h, \gamma - 1) h \in A$. As a result,
\[
G_S / H_S = \sum_{\chi \in H} G_{\chi, S}(T) \mathbb{F}_{\chi, T} e_{\chi} = \theta_S,
\]
for any prime $p$. Since $H_S = (\gamma - 1)e + (1 - e)$, we obtain $c_{\infty} G_S = d_{\infty} \theta_S$. Hence, for the $p$-adic pseudo-measure $\theta_S$ on $G_{\infty}$, we have $c_{\infty} G_S = d_{\infty} \theta_S \in \mathbb{A}$. 

Let $\bar{E} = E(\zeta_{2p})$ be the field obtained by adjoining a primitive $2p$-th root of unity $\zeta_{2p}$ to $E$, and let $\bar{E}_{\infty} := E_{\infty}(\zeta_{2p}) = E(\mu_{p^{\infty}})$ be the $\mathbb{Z}_p$-cyclotomic extension of $\bar{E}$, where $\mu_{p^{\infty}}$ is the group of all $p$-power roots of unity. We denote by $\tilde{G}_{\infty}$ the Galois group of $\bar{E}_{\infty}/F$. Since $\bar{E}_{\infty}$ contains all $p$-power roots of unity, we have the cyclotomic character
\[
\rho : \tilde{G}_{\infty} \to \mathbb{Z}_p^* = \text{Aut}(\mu_{p^{\infty}})
\]
of $\tilde{G}_{\infty}$. We extend the definitions of a Tate twisted module and an inverse module to the following:

- Let $t_n$ be the unique continuous isomorphism of $\mathcal{O}$-algebras
\[
t_n : \mathcal{O}[[\tilde{G}_{\infty}]] \to \mathcal{O}[[\tilde{G}_{\infty}]],
\]
which satisfies $t_n(g) = \rho(g)^n \cdot g$ for all $g \in \tilde{G}_{\infty}$ and $n \in \mathbb{Z}$. For a $\mathcal{O}[[\tilde{G}_{\infty}]]$-module $M$ let the Tate twisted module $M(n)$ be the same underlying group $M$ with a new $\mathcal{O}[[\tilde{G}_{\infty}]]$-action given by $\sigma * m := t_n(\sigma)m$ for $\sigma \in \mathcal{O}[[\tilde{G}_{\infty}]]$ and $m \in M$. For even $n$, we note that it is enough to replace $\bar{E}_{\infty}$ by its maximal real subfield $\tilde{E}_{\infty}^+$ to have the isomorphisms $t_n$.

- Let $\iota$ be the unique continuous isomorphism of $\mathcal{O}$-algebras
\[
\iota : \mathcal{O}[[G_{\infty}]] \to \mathcal{O}[[G_{\infty}]],
\]
which satisfies $\iota(g) = g^{-1}$ for all $g \in G_{\infty}$. For a $\mathcal{O}[[G_{\infty}]]$-module $M$, let the inverse module $M^\#$ be the same underlying group $M$ with a new $\mathcal{O}[[G_{\infty}]]$-action given by $\sigma * m := \iota(\sigma)m$ for $\sigma \in \mathcal{O}[[G_{\infty}]]$ and $m \in M$. In the following we mean by the ideal generated by $m^\#$, for any $m \in \mathcal{O}[[G_{\infty}]]$, the inverse ideal $(m)^\#$ of $(m)$.

**Lemma 3.3.** Assume that $E$ is the maximal real subfield of $\bar{E} = E(\zeta_{2p})$ where $\zeta_{2p}$ is a primitive $2p$-th root of unity. For all even $n$ we have:
\[
(\iota \circ t_n)(G_S) = \sum_{\psi \in H} G_{\psi - 1, \omega^n, S}(u^n(\gamma)^{-1} - 1) \cdot e_{\psi},
\]
\[
(\iota \circ t_n)(H_S) = \sum_{\psi \in H} H_{\psi - 1, \omega^n, S}(u^n(\gamma)^{-1} - 1) \cdot e_{\psi},
\]
where $u = \kappa(\gamma)$.
Proof. Under the assumptions of the lemma we first note that $E_\infty$ is the maximal real subfield of the field $E_\infty(\zeta_{2p})$ which contains all $p$-power roots of unity. So the actions of $t_n$ on $G_S$ and $H_S$ are defined for all even $n$. Now it suffices to observe that $(\iota \circ t_n)(\gamma - 1) = u^n \gamma^{-1} - 1$ and $(\iota \circ t_n)(e_\psi) = e_{\psi^{-1} \omega^n}$.

This lemma yields the following equality:

$$(\pi \circ \iota \circ t_n)G_S / H_S = \sum_{\chi \in G} \frac{G_{\chi^{-1} \omega^n, S}(u^n - 1)}{H_{\chi^{-1} \omega^n, S}(u^n - 1)} \cdot e_{\chi},$$

where $\pi : A \to \mathbb{Z}_p[G]$ is the projection mapping $\gamma - 1$ to zero, and $u = \kappa(\gamma)$. Therefore, we obtain:

**Corollary 3.4.** If we assume that $E$ is the maximal real subfield of $\bar{E} = E(\zeta_{2p})$ where $\zeta_{2p}$ is a primitive 2$p$-th root of unity, and that $n$ is even, then

$$(\pi \circ \iota \circ t_n)G_S / H_S = \Theta_{E/F}^S(1 - n)$$

**Remark 3.5.** We note that in the non-dyadic $L$-functions we have defined, the set $S$ can be replaced by $S_f$, since infinite primes have no influence on the definitions.

4 An Equivariant Main Conjecture in Iwasawa Theory

We recall that for the abelian extension $E/F$ of totally real number fields, $E_\infty$ (resp. $F_\infty$) is the cyclotomic $\mathbb{Z}_p$-extension of $E$ (resp. $F$), $H = \text{Gal}(E_\infty/F_\infty)$, and $G_\infty = \text{Gal}(E_\infty/F)$, which is abelian and hence of the form $G_\infty = H \times \Gamma$ for $\Gamma \simeq \mathbb{Z}_p$. We also recall that $d_\infty = e_\infty((\gamma - 1)e + (1 - e))$ is a non-zero divisor in the augmentation ideal of $A = \mathbb{Z}_p[[G_\infty]]$ so that $A/d_\infty A$ is a finitely generated $\mathbb{Z}_p$-free module, e.g. $d_\infty = \gamma - 1$.

**Conjecture 4.1.** (The Equivariant Main Conjecture). With notations as above, we have the following equality of ideals in $A$:

$$\text{Fitt}_A(Z^*_E) = (e_\infty G^*_S)$$

**Remark 4.2.** For any odd prime $p$, the formulation of the Equivariant Main Conjecture 4.1 is equivalent to the formulation of Ritter-Weiss in [35] (cf. [28], §2, (CPE2)). We note that Ritter-Weiss use the translation functor to define $\mathcal{Y}_\infty$, which equals to $\mathcal{Y}_\infty = \frac{\Delta \mathcal{H}}{\Delta \mathcal{H} \Delta \mathcal{G}}$. Here $\Delta(\mathcal{G}, \mathcal{H}) = \ker(Z_p[[\mathcal{G}]] \to Z_p[[G_\infty]])$, which is the same as $(\Delta \mathcal{H}) Z_p[[\mathcal{G}]]$ (cf. for example page 275 in [31]). As a result, $\mathcal{Y}_\infty = \frac{\Delta \mathcal{H}}{\Delta \mathcal{H} \Delta \mathcal{G}} = H_0(\mathcal{H}, \Delta \mathcal{G})$, which is the same as the definition used in this article.

Under the assumption $\mu = 0$ we prove that Conjecture 4.1 follows from the classical Main Conjecture in Iwasawa theory [47]. For some technical reasons, we need to apply the contravariant functors $E^i(-) := Ext^i_{A}(-, A)$ to $Z_{E}^*$, for $i = 0, 1$. We will see that $E^1(Z_{E}^*)$ is a finitely generated $A$-torsion module of projective dimension at most one, whose Fitting ideal is generated by the
modified equivariant $L$-function. First, we recall the definition and some basic properties of Fitting ideals (see [30] for more properties).

For a commutative ring $R$ with identity, the Fitting ideal $\text{Fitt}_R(M)$ of a finitely presented $R$-module $M$ is defined as follows: Given a presentation of $M$ as

$$ R^a \xrightarrow{h} R^b \rightarrow M \rightarrow 0, $$

let $A$ be the matrix associated to the map $h$. The (initial) Fitting ideal of $M$ is defined to be the ideal of $R$ generated by all $b$-minors of $A$ if $a \geq b$, and $(0)$ otherwise. Here are some properties:

1. $\text{Fitt}_R(M)$ is a finitely generated ideal of $R$ satisfying

$$ (\text{Ann}_R(M))^b \subseteq \text{Fitt}_R(M) \subseteq \text{Ann}_R(M), $$

where $\text{Ann}_R(M)$ is the annihilator ideal of $M$ and $b$ is an integer so that $M$ can be generated by $b$ elements as a $R$-module.

2. If $M \twoheadrightarrow M'$ is a surjective map of finitely presented $R$-modules, then

$$ \text{Fitt}_R(M) \subseteq \text{Fitt}_R(M'). $$

3. If $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$ is an exact sequence of finitely presented $R$-modules, then

$$ \text{Fitt}_R(M') \cdot \text{Fitt}_R(M'') \subseteq \text{Fitt}_R(M). $$

Moreover, we have equality if the exact sequence splits, i.e.

$$ \text{Fitt}_R(M' \oplus M'') = \text{Fitt}_R(M') \cdot \text{Fitt}_R(M''). $$

4. If $M \cong R/a$ is a cyclic module, then

$$ \text{Fitt}_R(M) = \text{Ann}_R(M) = a. $$

More generally, if we apply the previous property to a direct sum of $n$ cyclic $R$-modules

$$ M \cong R/a_1 \oplus R/a_2 \oplus \cdots \oplus R/a_n, $$

then we obtain

$$ \text{Fitt}_R(M) = a_1 a_2 \cdots a_n. $$

5. Let $M$ be a finite $R$-module for a group ring $R$ of a finite abelian group with coefficients in $\mathbb{Z}_p$. If $M$ is cyclic as a $\mathbb{Z}_p$-module, then

$$ \text{Fitt}_R(M^\ast) = \text{Ann}_R(M^\ast) \cong \text{Ann}_R(M) = \text{Fitt}_R(M), $$

where $M^\ast = \text{Hom}(M, \mathbb{Q}_p/\mathbb{Z}_p)$ is the Pontryagin dual equipped with the covariant action.
We recall that \# denotes the inverse action defined in (3.4). In the next lemma we list some general properties of $E^i(M)$ for an $\mathcal{A}$-module $M$. For a proof see propositions 5.4.17, 5.5.6 and corollary 5.5.7 in [31], or [17].

**Lemma 4.3.** Let $M$ be an $\mathcal{A}$-module, let $\alpha(M)$ denote the adjoint of $M$ with the contravariant action, and let $M^\vee = Hom_{\mathbb{Z}_p}(M, \mathbb{Z}_p)$ be the dual with the contravariant $G_\infty$-action. Then

1. $E^i(M) = Ext^i_{\mathcal{A}}(M, \mathcal{A})$ as $\mathcal{A}$-modules for any $\mathcal{A}$-module $M$ and $i \geq 0$,

2. $E^1(M)\# \simeq \alpha(M)$ as $\mathcal{A}$-modules, provided $M$ is a finitely generated $\mathcal{A}$-torsion module,

3. $E^1(M)\# \simeq M^\vee$ as $\mathcal{A}$-modules, provided $M$ is a $\mathcal{A}$-torsion module with trivial $\mu$-invariant, i.e. $M$ is a finitely generated $\mathbb{Z}_p$-module.

We list some results obtained by applying the contravariant functors $E^i(-)$ for $i = 1, 2$, to some of the exact sequences arising from diagram (2.8). We first remark that $E^i(\mathcal{A}) = Hom_{\mathcal{A}}(\mathcal{A}, \mathcal{A})$ is a left exact functor, and that $E^i(\mathcal{A}) = 0$ for $i \geq 1$, since $pd_{\mathcal{A}}(\mathcal{A}) = 0$ (cf. Proposition 5.2.11 in [31]).

**Lemma 4.4.** The $\mathcal{A}$-module $E^1(\mathbb{Z}_\infty^f)^\#$ is of projective dimension at most one, and

$$Fitt_{\mathcal{A}}(E^1(\mathbb{Z}_\infty^f)^\#) = Fitt_{\mathcal{A}}(\mathbb{Z}_\infty^f)^\#.$$

**Proof.** This lemma is a consequence of Proposition 2 in [13] and Lemma 4.3. We give here a direct proof, since we need some of the methods in the proof of Lemma 4.5 below: We first apply $E^i(-)$ to the last column of diagram (2.8). We observe that $Hom_{\mathcal{A}}(\mathbb{Z}_\infty^f, \mathcal{A})$ is the set of all morphisms in $Hom_{\mathcal{A}}(\Delta G_\infty, \mathcal{A})$, whose restriction to $d_\infty \mathcal{A}$ vanishes. This observation and the choice of $d_\infty \mathcal{A}$ as a non-zero divisor imply that $E^0(\mathbb{Z}_\infty^f) = 0$. By part 1 of Lemma 4.3 $E^0(\mathcal{X}_\infty^f)$ is also trivial for the $\mathcal{A}$-torsion module $\mathcal{X}_\infty^f$. Hence by applying the contravariant functor $E^i(-)$ to the last row of diagram (2.8), we obtain $E^0(\mathbb{Z}_\infty^f) = 0$. On the other hand $E^i(\mathcal{A})$ is trivial for $i \geq 1$ as we mentioned before. Therefore, applying $E^i(-)$ to the middle column of diagram (2.10) leads to the exact sequence

$$0 \to E^0(\mathcal{A})^r + 1 \to E^0(\mathcal{A})^{r+1} \to E^1(\mathbb{Z}_\infty^f) \to 0.$$

Here $E^0(\Psi)$ is the transpose of $\Psi$. We now apply “$\#$” to the exact sequence above to obtain:

$$0 \to \mathcal{A}^{r+1} \to E^0(\Psi)^\# \to E^1(\mathbb{Z}_\infty^f)^\# \to 0,$$

which shows that the projective dimension of the $\mathcal{A}$-module $E^1(\mathbb{Z}_\infty^f)^\#$ is at most one. To complete the proof it is enough to note that the Fitting ideal of the $\mathcal{A}$-module $E^1(\mathbb{Z}_\infty^f)^\#$ is given by the determinant of $E^0(\Psi)^\#$, whereas the Fitting ideal of $\mathbb{Z}_\infty^f$ is given by the determinant of the map $\Psi$ defined in diagram (2.10).
Lemma 4.5. We have the following exact sequence of finitely generated \(k\)-torsion modules:

\[ 0 \to \mathbb{Z}_p \to (k/d_\infty k)^\# \to E^1(z_{\infty})^\# \to 0. \]

Proof. We saw in the proof of Lemma 4.4 that \(E^0(z_{\infty})\) is trivial. As a consequence of Proposition 5.2.11 in [31] we obtain that \(E^2(\mathbb{Z}_p)\) is trivial as well, since the projective dimension of the \(\Lambda\)-module \(\mathbb{Z}_p\) is one. By applying \(E^i(\cdot)\) to the exact sequence (2.9) we therefore obtain the exact sequence

\[ 0 \to E^1(\mathbb{Z}_p) \to E^1(k/d_\infty k) \to E^1(z_{\infty}) \to 0. \]

By part 2 of Lemma 4.3 together with the fact that an elementary module is isomorphic to the inverse module of its adjoint (cf. 1.3 in [16]) we have \(E^1(\mathbb{Z}_p)^\# \cong \mathbb{Z}_p\), where \(\mathbb{Z}_p\) has the trivial \(G_\infty\)-action. We also have the isomorphism \(E^1(k/d_\infty k)^\# \cong (k/d_\infty k)^\#\), since \(\text{pd}_A(k) = 0\). Therefore, by applying “\(\#\)” to the exact sequence above, we obtain:

\[ 0 \to \mathbb{Z}_p \to (k/d_\infty k)^\# \to E^1(z_{\infty})^\# \to 0. \]

Lemma 4.6. We have the following exact sequence of finitely generated \(k\)-torsion modules:

\[ 0 \to E^1(z_{\infty}) \to E^1(\mathbb{Z}_p) \to E^1(z_{\infty}) \to 0. \]

Proof. First we observe that \(E^2(z_{\infty})\) is trivial by applying \(E^i(\cdot)\) to the exact sequence (2.9) and by noting that the projective dimensions of \(\mathbb{Z}_p\) and \(k/d_\infty k\) are both one. Now we apply \(E^i(\cdot)\) to the last row of diagram (2.8) to obtain the exact sequence above. We note that the surjectivity of the last map in the diagram follows from the observation that \(E^2(z_{\infty}) = 0\), and that the injectivity of the first map in the diagram is a consequence of the observation that \(E^0(\mathbb{X}_{\infty}) = 0\) in the proof of lemma (4.4).

We combine Lemmas 4.5 and 4.6 to obtain the following theorem:

Theorem 4.7. We have the following exact sequence of finitely generated \(k\)-torsion modules:

\[ 0 \to \mathbb{Z}_p \to (k/d_\infty k)^\# \to E^1(\mathbb{Z}_p)^\# \to E^1(z_{\infty})^\# \to 0, \]

in which

\[ \text{pd}_A((k/d_\infty k)^\#) \leq 1 \quad \text{and} \quad \text{pd}_A(E^1(\mathbb{Z}_p)^\#) \leq 1. \]

The \(\Lambda\)-module \(E^1(\mathbb{X}_{\infty})^\#\) is isomorphic to the adjoint of \(\mathbb{X}_{\infty}\) by part 2 of Lemma 4.3 and so it is a finitely generated \(\mathbb{Z}_p\)-free module under the assumption \(\mu = 0\). Therefore we obtain from Theorem 4.7 the first statement in the following proposition:

Documenta Mathematica 18 (2013) 749–783
Proposition 4.8. Let $d_\infty \in \Delta G_\infty$ be a non-zero divisor so that $\mathcal{A}/d_\infty \mathcal{A}$ is a finitely generated $\mathbb{Z}_p$-free module. Then, under the assumption $\mu = 0$, the sequence

$$0 \to \mathbb{Z}_p \to (\mathcal{A}/d_\infty \mathcal{A})^\# \to E^1(\mathcal{Z}_\infty^f)^\# \to E^1(\mathcal{X}_\infty^f)^\# \to 0$$

is an exact sequence of finitely generated $\mathbb{Z}_p$-free modules. Moreover, if we consider this sequence as an exact sequence of $\mathbb{Z}_p[\Gamma]$-modules, then under the assumptions of $\mu = 0$ we have

$$pd_{\mathbb{Z}_p[\Gamma]}((\mathcal{A}/d_\infty \mathcal{A})^\#) = 0 \quad \text{and} \quad pd_{\mathbb{Z}_p[\Gamma]}(E^1(\mathcal{Z}_\infty^f)^\#) = 0.$$

Proof. We only need to prove the second part. We first remark that $\mathcal{A}/d_\infty \mathcal{A}$ and $E^1(\mathcal{Z}_\infty^f)$ are both $H$-cohomologically trivial by Proposition 2.2 in [32], since their projective dimensions are at most one as $\mathcal{A}$-modules. By a classical theorem of Nakayama $pd_{\mathbb{Z}_p[\Gamma]}(M) = 0$ if and only if $M$ is $\mathbb{Z}_p$-free and $H$-cohomologically trivial ($p$-adic version of Theorem 8 in [40], Chapter IX, §5). Therefore, both modules are of projective dimension zero as $\mathbb{Z}_p[\Gamma]$-modules.

To finish the proof that the Equivariant Main Conjecture follows from the classical Main Conjecture under the assumption $\mu = 0$, we first review the definition of the determinantal ideal, which plays a role similar to that of the characteristic ideal for some $\Lambda$-modules with an extra group action: For a commutative ring $R$ with identity, a finitely generated projective $R$-module $P$ and $f \in \text{End}_R(P)$, the determinant of $f$ is defined as

$$\text{det}_R(f \mid P) := \text{det}_R(f \oplus \text{id}_Q \mid P \oplus Q),$$

where $Q$ is a complement of $P$, i.e. $P \oplus Q$ is free. One can check that the definition is independent of $Q$ by using Schanuel’s lemma. By the same strategy, since $P \otimes_R R[X]$ is a finitely generated projective $R[X]$-module, the monic polynomial $\text{det}_R(X - f \mid P) \in R[X]$ is defined to be

$$\text{det}_R(X - f \mid P) := \text{det}_{R[X]}(\text{id}_P \otimes X - f \otimes 1 \mid P \otimes_R R[X]),$$

for any projective $R$-module $P$. One can see that these definitions are well-behaved under base-change, i.e.

$$\begin{align*}
\text{det}_R(f \mid P) &= \text{det}_R(f \otimes \text{id}_{R'} \mid P \otimes R') \\
\text{det}_R(X - f \mid P) &= \text{det}_{R'}(X - (f \otimes \text{id}_{R'}) \mid P \otimes R'),
\end{align*}$$

(4.1)

where $R'$ is any commutative $R$-algebra. We have the following general proposition:

Proposition 4.9. ([15], Proposition 7.2). Let $R$ be a commutative, semi-local, compact topological ring and let $\Gamma$ be a pro-cyclic group with topological generator $\gamma$. Let $M$ be a topological $R[[\Gamma]]$-module, which is projective and finitely generated as an $R$-module. Let

$$F(X) := \text{det}_R(X - m_\gamma \mid M),$$

Documenta Mathematica 18 (2013) 749–783.
where \( m_\gamma \) is the \( R[[\Gamma]] \)-module automorphism of \( M \) given by multiplication by \( \gamma \). Then the following holds:

1. \( M \) is finitely presented as an \( R[[\Gamma]] \)-module. If we let \( F(\gamma) \) be the image of \( F(X) \) via the \( R\)-algebra morphism \( R[X] \to R[[\Gamma]] \) sending \( X \) to \( \gamma \), we have an equality of \( R[[\Gamma]] \)-ideals

\[
\text{Fitt}_{R[[\Gamma]]}(M) = (F(\gamma)).
\]

2. If we view \( M_\gamma^R = \text{Hom}_R(M, R) \) as a topological \( R[[\Gamma]] \)-module with the covariant \( \Gamma \)-action, then

\[
\text{Fitt}_{R[[\Gamma]]}(M) = \text{Fitt}_{R[[\Gamma]]}(M_\gamma^R).
\]

3. If we view \( M^\vee = \text{Hom}_{\mathbb{Z}_p}(M, \mathbb{Z}_p) \) as a topological \( R[[\Gamma]] \)-module with the covariant \( \Gamma \)-action, where \( R = \mathbb{Z}_p[G] \) and \( G \) is a finite abelian group, then

\[
\text{Fitt}_{R[[\Gamma]]}(M) = \text{Fitt}_{R[[\Gamma]]}(M^\vee).
\]

By using Proposition 4.9 for the ring \( R = \mathbb{Z}_p[H] \) and the finitely generated \( R \)-modules \( M = E^1(\mathbb{Z}_\infty^f)^\# \) and \( M = (\mathbb{A}/d_\infty\mathbb{A})^\# \), which are projective by Proposition 4.8, we obtain:

**Lemma 4.10.** If \( m_\gamma \) denotes the \( R[[\Gamma]] \)-module automorphism of \( M \) given by multiplication by \( \gamma \), then

\[
\begin{align*}
\text{Fitt}_{\mathbb{A}}(E^1(\mathbb{Z}_\infty^f)^\#) &= (\det_{\mathbb{Z}_p[\Gamma]}((T + 1) - m_\gamma | E^1(\mathbb{Z}_\infty^f)^\#)), \\
\text{Fitt}_{\mathbb{A}}((\mathbb{A}/d_\infty\mathbb{A})^\#) &= (\det_{\mathbb{Z}_p[\Gamma]}((T + 1) - m_\gamma | (\mathbb{A}/d_\infty\mathbb{A})^\#)).
\end{align*}
\]

Let \( \mathcal{O} \) be the ring of integers obtained by adjoining all character values of the characters of \( H \) to \( \mathbb{Z}_p \), let \( \pi \) be a fixed uniformizer in \( \mathcal{O} \) and let \( Q(\mathcal{O}) \) denote the field of fractions of \( \mathcal{O} \). We consider \( \mathcal{O} \) and \( Q(\mathcal{O}) \) as \( \mathbb{A} \)-modules with trivial \( G_\infty \) action. We note that for the idempotent \( e \) attached to the trivial character of \( H \) we have \( H_\mathcal{S}(T) = T \cdot e + (1 - e) \) using the identification (2.2) (see (3.1) for the definition of \( H_\mathcal{S}(T) \)). Therefore, using Lemma 4.10 we obtain the following lemma:

**Lemma 4.11.** We have the following equalities of ideals in \( Q(\mathcal{O})[[H]][[\Gamma]] \):

\[
\begin{align*}
(H_\mathcal{S}(T)) &= (\det_{Q(\mathcal{O})[[H]]}((T + 1) - m_\gamma | Q(\mathcal{O}))), \\
(d^m_\mathcal{S}) &= (\det_{Q(\mathcal{O})[[H]]}((T + 1) - m_\gamma | (Q(\mathcal{O})[[H]][[\Gamma]]/d_\infty)^\#)).
\end{align*}
\]

**Remark 4.12.** Any character \( \chi \) of \( H \) can be extended to a \( Q(\mathcal{O})[[X]] \)-algebra homomorphism, for a variable \( X \), and to a \( Q(\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}[[\Gamma]] \)-algebra homomorphism

\[
\begin{align*}
\chi : Q(\mathcal{O})[[X]] &\to Q(\mathcal{O})[[X]], \\
\chi : Q(\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}[[G_\infty]] &\to Q(\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}[[\Gamma]],
\end{align*}
\]

which maps \( h \to \chi(h) \) for \( h \in H \).
Lemma 4.13. We have the following equality of ideals in $O[[\Gamma]]$ under the assumption $\mu = 0$:

$$(\det_{Q(O)}((T + 1) - m_\gamma | e_\psi(\mathcal{X}_\infty^f \otimes_{Z_p} Q(O)))^\# = (\det_{Q(O)}((T + 1) - m_\gamma | e_\psi(E^1(\mathcal{X}_\infty^f)^\# \otimes_{Z_p} Q(O))))^\#.$$ 

Proof. Since the $R := O_\psi[[\Gamma]]$-torsion module $M_1 := e_\psi(\mathcal{X}_\infty^f \otimes_{Z_p} Q(O))$ is of projective dimension at most one (cf. for example Lemma 2.4 in [32]), the $R$-torsion module $M_2 := e_\psi(E^1(\mathcal{X}_\infty^f)^\# \otimes_{Z_p} Q(O))$ is also of projective dimension at most one. Hence by the first part of Proposition 4.9 it is enough to show that $\text{Fitt}_R(M_1)^{\#} = \text{Fitt}_R(M_2)$. But this is a direct consequence of the second part of Lemma 4.3 and Proposition 2 in [13].

The equality of fractional ideals

$$(G^*_\psi, S(T)) = (\det_{Q(O)}((T + 1) - m_\gamma | e_\psi(\mathcal{X}_\infty^f \otimes_{Z_p} Q(O))))$$

in $Q(O)[[T]]$ for any character $\psi$ of $H$ (see equality (1.2) and part 1 of Proposition 4.9). Here we note that the assumption $\mu = 0$ implies the vanishing of the $\mu$-invariants of $\mathcal{X}^f_{\infty, \psi}$ for all (even) characters $\psi$ of $H$. Hence, using Lemma 4.13, we obtain the following equality of fractional ideals in $Q(O)[[T]]$:

$$(\psi(G^*_\psi, S(T))^\#) = (G^*_\psi, S(T)^\#) = (\det_{Q(O)}((T + 1) - m_\gamma | e_\psi(E^1(\mathcal{X}_\infty^f)^\# \otimes_{Z_p} Q(O)))) = (\psi(\det_{Q(O)[\Gamma]}((T + 1) - m_\gamma | E^1(\mathcal{X}_\infty^f)^\# \otimes_{Z_p} Q(O))))).$$

Consequently the exact sequence

$$0 \to Z_p \to (\mathbb{A}/d_\infty \mathbb{A})^\# \to E^1(Z_\infty^f)^\# \to E^1(X_\infty^f)^\# \to 0$$

in Theorem 4.7, and Lemma 4.10 together with the base-change property of determinants (cf. (4.1)) imply the following equality of ideals in $O[[T]]$:

$$\psi((c_\infty G^*_\psi(T))^\#) = (\psi(\det_{Q(O)[\Gamma]}((T + 1) - m_\gamma | E^1(Z_\infty^f)^\# \otimes_{Z_p} Q(O))))).$$

Before completing the proof we recall that the $\mu$-invariant $\mu(F)$ of a power series $F \in O[[T]]$ is the largest exponent $\mu \geq 0$ such that $f \in (\pi^n)O[[T]]$. For $F \in \mathbb{A}$ we define the $\mu$-invariant of $F$ to be zero if $\mu(\chi(F)) = 0$ for any $p$-adic valued character $\chi$ of $H$.

Let $F := \det_{Z_p[H]}((T + 1) - m_\gamma | E^1(Z_\infty^f)^\#)$ and $G := (c_\infty G^*_\psi(T))^\#$ in $\mathbb{A}$ (cf. Lemma 3.2). Then

- $\mu(F) = 0$, since the determinantal polynomial $F \in Z_p[H][[T]]$ of the projective $Z_p[H]$-module $E^1(Z_\infty^f)^\#$ (cf. Proposition 4.8) is monic.
• $\mu(G) = 0$, since for any $p$-adic character $\psi$ of the group $H$, we have
$$\mu(\psi(G^*_S)) = \mu(g^*_S \cdot u_{\psi,S}) = 0, \quad \mu(\psi(H_S)) = 0, \quad \mu(\psi(d_\infty)) = 0.$$  

Here we note that the determinantal polynomials of the field $Q(O)$ and the projective $\mathbb{Z}_p[H]$-module $(h/d_\infty h)^\#$ (cf. Proposition 4.8), which are generated by $H_S$ and $d_\infty^\#$, respectively (cf. Lemma 4.11), are monic.

• $(\psi(F)) = (\psi(G))$, using equality (4.2).

In the terminology of [2], $R := \mathbb{Z}_p[H]$ is admissible for the abelian group $H$, i.e. $R$ is a finite product of strictly admissible rings $R_i$, which means that each $R_i$ is separated and complete in the $\text{rad}(R_i)$-adic topology and also $R_i/\text{rad}(R_i)$ is a skew field. Since the $\mu$-invariants of $F, G \in R[[T]]$ are both zero, Proposition 2.1 in [2] as an equivariant Weierstrass Preparation Theorem implies the existence of unique distinguished polynomials $f^*, g^* \in R[[T]]$ and units $u, v \in (R[[T]])^\times$ such that
$$F = u \cdot f^* \quad \text{and} \quad G = v \cdot g^*.$$  

We apply a $p$-adic character $\psi$ of $H$ to both sides, and note that $\psi(f^*)$ and $\psi(g^*)$ are both distinguished polynomials in $O[[T]]$, and that $\psi(u), \psi(v) \in O[[T]]^\times$ are units. Hence the equality $(\psi(F)) = (\psi(G))$ together with the uniqueness of the Weierstrass decomposition yields
$$\psi(f^*) = \psi(g^*)$$
for any $p$-adic character $\psi$ of $H$. Therefore, $f^* = g^*$ and $F = uv^{-1}G$. The equality $(F) = (G)$ now implies the following:

$$(\iota(c_\infty G^*_S)) = (\text{det}_{\mathbb{Z}_p[H]}((T + 1) - m_\gamma | E^1(\mathbb{Z}_S^\infty)^\#))$$

$$= \text{Fitt}_h(E^1(\mathbb{Z}_S^\infty)^\#) \quad \text{by Lemma 4.10} \quad (4.3)$$

$$= \text{Fitt}_h(\mathbb{Z}_S^\infty)^\# \quad \text{by Lemma 4.4.}$$

Consequently, the equality
$$\text{Fitt}_h(\mathbb{Z}_S^\infty) = (c_\infty G^*_S)$$
holds, and this completes the proof of the Equivariant Main Conjecture 4.1 under the assumptions of the classical Main Conjecture and of $\mu = 0$.

**Theorem 4.14.** The Equivariant Main Conjecture 4.1 follows from the classical Main Conjecture in Iwasawa theory under the assumption $\mu = 0$.

**Remark 4.15.** For any odd prime $p$, or for the prime 2 if $F$ is an absolutely abelian number field, the classical Main Conjecture holds, and hence the Equivariant Main Conjecture 4.1 is verified under the assumption $\mu = 0$.  

---

**Documenta Mathematica 18 (2013) 749–783**
We recall that the assumption $\mu = 0$ holds for any absolute abelian number field $E$, i.e. for any number field $E$ whose Galois group over $\mathbb{Q}$ is abelian, by the result of Ferrero and Washington in [10]. Hence

**Corollary 4.16.** If $E$ is an absolute abelian number field, the Equivariant Main Conjecture 4.1 holds unconditionally.

5 The Coates-Sinnott Conjecture as an application

Let $E/F$ be an abelian extension of number fields with Galois group $G$, let $n \geq 2$ be an integer, and let $p$ be an arbitrary prime. Let $S$ be a finite set of primes in $F$ containing the primes above $p$, the primes ramified in $E$ and the infinite primes, and let $S_f$ denote the set of all finite primes in $S$. Let

$$\Theta_{E/F}^S(s) = \sum_{\chi \in \hat{G}} L_{E/F}^S(s, \chi^{-1}) \cdot e_{\chi}$$

be the $G$-equivariant $S$-incomplete $L$-function associated to $E/F$. We recall that for an integer $n \geq 1$ by a result of Siegel [41]

$$\Theta_{E/F}^S(1 - n) \in \mathbb{Q}[G],$$

$$\text{Ann}_{\mathbb{Z}[G]}(H^0(E, \mathbb{Q}/\mathbb{Z}(n))) \cdot \Theta_{E/F}^S(1 - n) \subset \mathbb{Z}[G].$$

For $n \geq 1$ the $n$-th higher Stickelberger ideal is defined as follows:

$$\text{Stick}_{E/F}^S(n) := \text{Ann}_{\mathbb{Z}[G]}(H^0(E, \mathbb{Q}/\mathbb{Z}(n))) \cdot \Theta_{E/F}^S(1 - n) \subset \mathbb{Z}[G].$$

**Remark 5.1.** The classical theorem of Stickelberger states that

$$\text{Stick}_{E/F}^S(1) \subseteq \text{Ann}_{\mathbb{Z}[G]}(\text{Cl}(O_E)),$$

where $\text{Cl}(O_E)$ denotes the class group of $O_E$. Brumer conjectured that the same holds for any abelian extension $E/F$ of number fields.

The original formulation of the Coates-Sinnott Conjecture is as follows:

**Conjecture 5.2.** (The Coates-Sinnott Conjecture, $K$-theoretic version). Let $E/F$ be an abelian Galois extension of number fields with Galois group $G$, and let $n \geq 2$. Then

$$\text{Stick}_{E/F}^S(n) \subseteq \text{Ann}_{\mathbb{Z}[G]}(K_{2n-2}(O_E)).$$

As a consequence of the work of Voevodsky (cf. [45]) the Quillen-Lichtenbaum Conjecture holds, i.e. for all odd primes $p$ the étale Chern characters defined by Soulé [42]

$$ch_{i,n}^{(p)} : K_{2n-i}(O_F) \otimes \mathbb{Z}_p \to H_{et}^{2i}(O'_F, \mathbb{Z}_p(n))$$
are isomorphisms for \( i = 1, 2 \), and all \( n \geq 2 \). Here \( O_F' = O_F[1/p] \). The surjectivity of the Chern characters was proved by Soulé for even \( n \) (see [42]) and by Dwyer and Friedlander in general (see [7]).
