Abstract

Long-range interactions for linearly elastic media resulting in nonlinear dispersion relations are modelled by an initial-value problem for an integro-differential equation (IDE) that incorporates non-local effects. Interpreting this IDE as an evolutionary equation of second order, well-posedness in $L^\infty(\mathbb{R})$ as well as jump relations are proved. A numerical approximation based upon quadrature is suggested and carried out for two examples, one involving jump discontinuities in the initial data corresponding to a RIEMANN-like problem.

Key words: Long-range interactions, peridynamic theory, nonlinear dispersion relations, integro-differential equation, existence and uniqueness, jump discontinuity, numerical approximation

MSC (2000): 74Hxx, 74B99, 45K05, 34G10, 47G20, 65R20

1 Introduction

Motivated by the so-called peridynamic theory of solids (cf. SILLING [8]), we are interested in the integro-differential equation (IDE)

$$\partial_t^2 u(x,t) = \int_{-\infty}^{\infty} k(x,\xi)u(\xi,t)\,\mathrm{d}\xi + c(x)u(x,t) + b(x,t)\,, \quad (x,t) \in \mathbb{R} \times (0,T)\,,$$
(1.1)

where $\mathbb{R}$ denotes the unbounded spatial domain, $(0,T)$ with $T > 0$ is the time interval under consideration, c is a time-independent coefficient and b an inhomogeneity. We look for solutions $u = u(x,t)$ to equation (1.1) that fulfill the initial conditions

$$u(\cdot,0) = u_0\,, \quad \partial_t u(\cdot,0) = v_0$$
(1.2)

for prescribed initial data u_0, v_0. In the context of continuum mechanics, u denotes the displacement field whereas $\partial_t u$ describes the velocity.

---

[1]This work was supported by a fellowship of the second author within the Postdoc-Programme of the German Academic Exchange Service (DAAD).

The kernel $k : \mathbb{R}^2 \to \mathbb{R}$ might be unsymmetric. However, the integral operator is often to be assumed of convolution type so that

$$k(x, \xi) = \tilde{k}(x - \xi) \quad \text{with} \quad \tilde{k}(z) = \tilde{k}(-z) , \quad z \in \mathbb{R} , \tag{1.3}$$

and the coefficient c is assumed to be constant and given by

$$c(x) \equiv - \int_{-\infty}^{\infty} \tilde{k}(z) \, \mathrm{d}z . \tag{1.4}$$

The peridynamic theory is a non-local model of integral type, which –in contrast to other such models– only involves the displacement field but *not* its gradient or higher-order spatial derivatives as will be discussed in Section 2. This might be an attractive feature, especially in settings that involve singularities. Formally, the peridynamic theory seems to be a continuous version of molecular dynamics; its linearisation resembles the equation of motion for a crystalline structure (cf. CZYCHOLL [3]). However, this similarity is misleading as the peridynamic theory is meant to apply at length scales *between* those of classical continuum mechanics and molecular dynamics. A discussion of the relation between non-local theories and atomistic models can be found, e. g., in CHEN *et al.* [2]. For a detailed description of a variety of non-local theories in continuum mechanics, we refer to KUNIN [5] and ROGULA [7]. Non-local models can be also found in the description of other natural phenomena. So LEE *et al.* [6] discuss an IDE of first-order in biomathematics modelling the dynamics of interacting individuals that coexist on a spatial landscape. One of the ideas behind is the description of density changes due to long-distance interactions.

Recently, WECKNER & ABEYARATNE [10] analysed the effects of long-range forces on the dynamics of an infinite *homogeneous* bar, corresponding to the IDE

$$\rho_0 \partial_t^2 u(x, t) = \int_{-\infty}^{\infty} C(\hat{x} - x)[u(\hat{x}, t) - u(x, t)] \, \mathrm{d}\hat{x} + h(x, t) , \ (x, t) \in \mathbb{R} \times (0, T) , \tag{1.5}$$

where ρ_0 is the constant density and the kernel C, the so-called micromodulus function, is of convolution type (1.3) due to the homogeneity. Using FOURIER transformations, the authors have shown that the general solution of (1.5) subject to the initial conditions (1.2) can be expressed in terms of a GREEN function. The motion has been found to be dispersive as a result of the long-range forces. The micromodulus C has been chosen such that the limit of short-range forces is in accordance with the classical results known for a linearly elastic medium. In addition, the first-order correction to classical local elasticity has been derived in order to characterise weak non-locality. The most striking observations made are concerning RIEMANN's problem with a discontinuous velocity in the beginning: Although the displacement field is initially continuous, a jump discontinuity occurs for all times $t > 0$ and remains stationary with respect to the LAGRANGIAN coordinates. Moreover, the height of a displacement jump oscillates around an average value for some materials while for others, it increases monotonically, eventually fracturing the material.

In this paper we generalise the equation of motion (1.5) to (1.1) taking into account inhomogeneities in both the inertial and the stiffness distribution resulting in

the more general kernel k and coefficient c. We prove existence and uniqueness of the mild solution to the initial-value problem for (1.1) in spaces of abstract functions with values in $L^\infty(\mathbb{R})$, the space of essentially bounded functions. As (1.5) is a special case of (1.1), this also completes the proof of uniqueness given in [10]. Moreover, the solution is explicitly given in terms of an infinite series of potencies of a stationary BARBASHIN operator applied to the initial conditions and the external force field. We also focus on regularity, an *a priori* estimate for the solution, and stability with respect to the data and the kernel. It is, furthermore, shown that a jump in either the initial conditions or the external force field generates a jump in the displacement field that is stationary with respect to its LAGRANGIAN coordinates. As an example, the RIEMANN problem is solved. Specialising the results to the homogeneous case, our results agree with those given in [10].

As a closed analytical solution cannot be expected in general, an efficient numerical method has to be developed. For the approximate solution in the case of piecewise continuous data u_0, v_0, b, we suggest a method that is based upon quadrature. For the numerical integration, we partition the domain of integration $\mathbb{R}$ corresponding to the jumps in the data and apply quadrature formulae on each of the integrals taken over intervals on which the data are continuous. The resulting initial value problem for a linear system of second-order differential equations can then be solved by standard methods. Examples are presented in order to illustrate the numerical approximation proposed. The numerical integration is based upon the GAUSS-HERMITE and composite trapezoidal quadrature.

The paper is organised as follows. In Section 2 we give a short introduction into the peridynamic theory of solids. As a motivation, we present two advantages of the non-local model in comparison to the classical, local model of continuum mechanics and we show how these advantages can be exploited for a number of interesting applications. In Section 3, under certain assumptions on the regularity of the kernel k in (1.1), the mathematical analysis is presented. A numerical approximation is suggested in Section 4. The method proposed is then illustrated in two examples for which analytical solutions are at hand. This allows us to validate the numerical results.

2 Modelling long-range forces in elasticity theory

In the peridynamic theory of a solid (cf. SILLING [8]), the force applied *on* the particle at position $\mathbf{x} \in \mathcal{R}$ *by* the particle at $\hat{\mathbf{x}} \in \mathcal{R}$ is characterised by a *pairwise force function* $\mathbf{f} = \mathbf{f}(\hat{\mathbf{x}}, \mathbf{x}, t)$. So the equation of motion for the particle at $\mathbf{x}$ reads as

$$\rho_0(\mathbf{x})\partial_t^2 \mathbf{u}(\mathbf{x}, t) = \int_{\mathcal{R}} \mathbf{f}(\hat{\mathbf{x}}, \mathbf{x}, t)\mathrm{d}\hat{\mathbf{x}} + \mathbf{h}(\mathbf{x}, t), \quad (\mathbf{x}, t) \in \mathcal{R} \times (0, T). \qquad (2.1)$$

Here, $\mathcal{R} \subseteq \mathbb{R}^3$ is the region occupied by the body, $\mathbf{x}$ is the position of a material point and $\rho_0(\mathbf{x})$ is the mass density at $\mathbf{x}$, all in the reference configuration. The motion is characterised by the displacement field $\mathbf{u} = \mathbf{u}(\mathbf{x}, t)$ and the material is characterised by $\mathbf{f}$. The value $\mathbf{f}(\mathbf{x}, \hat{\mathbf{x}}, t)$ of the pairwise force function denotes the force per unit reference volume applied on the particle at $\mathbf{x}$ at time t by a unit volume of material at $\hat{\mathbf{x}}$. The field $\mathbf{h}$ represents an external force density.

In the following, we restrict our considerations to the one-dimensional case. NEWTON's third law requires the symmetry $f(\hat{x}, x, t) = -f(x, \hat{x}, t)$. The constitutive response of the material is characterised by a function F, which relates the force between particles to the kinematics. Here, we assume that the relevant variables of the constitutive function are the positions in both the present and the reference configuration:

$$f(\hat{x}, x, t) = F(y(\hat{x}, t), y(x, t), \hat{x}, x)$$

where

$$y(x, t) = x + u(x, t)$$

is the momentary position of particle x at time t and u is the corresponding displacement. This excludes, for example, materials capable to remember their deformation history. From objectivity principles, the force between the two particles x and $\hat{x}$ cannot depend on the choice of the origin. The constitutive relation is thus given by

$$F(y(\hat{x}, t), y(x, t), \hat{x}, x) = \tilde{f}(\eta(\hat{x}, x, t), \hat{x}, x), \quad \eta(\hat{x}, x, t) := u(\hat{x}, t) - u(x, t).$$

A TAYLOR expansion with respect to the first argument of the function $\tilde{f}$ leads to

$$\tilde{f}(\eta(\hat{x}, x, t), \hat{x}, x) = \tilde{f}(0, \hat{x}, x) + \partial_\eta \tilde{f}(0, \hat{x}, x) \eta(\hat{x}, x, t) + \mathcal{O}(\eta(\hat{x}, x, t)^2).$$

Assuming small relative deformations η, equation (2.1) reduces to (1.1) in the one-dimensional case with $\mathcal{R} = \mathbb{R}$ and

$$k(x, \xi) := \frac{\partial_\eta \tilde{f}(0, \xi, x)}{\rho_0(x)}, \quad c(x) := -\int_{-\infty}^{\infty} \frac{\partial_\eta \tilde{f}(0, \xi, x)}{\rho_0(x)} \, \mathrm{d}\xi,$$

$$b(x, t) := \int_{-\infty}^{\infty} \frac{\tilde{f}(0, \xi, x)}{\rho_0(x)} \, \mathrm{d}\xi + \frac{h(x, t)}{\rho_0(x)}.$$

Assuming further a homogeneous material, equation (1.5) follows.

In what follows, we shall discuss two different applications in which the peridynamic theory seems to be of particular advantage compared to the classical theory of continuum mechanics.

The absence of spatial gradients has been the main motivation for the introduction of the peridynamic theory by SILLING [8]. This feature promises computational advantages, especially in settings that involve singularities such as problems arising in fracture mechanics. In the classical theory of elasticity, which is based upon partial differential equations, a discontinuity has to be accounted for by dividing the original domain into two subdomains and deriving additional jump conditions. However, discontinuities can form spontaneously and grow along trajectories not known in advance. So the classical method just described seems to be cumbersome for this kind of problems. In the peridynamic theory, the deformation of a body is described by an IDE that remains well-defined both in regular and singular regions of a body. This advantage is currently exploited at a commercial aircraft producer in order to calculate fatigue cracking and failure in composite materials using a code that has been developed by SILLING.

The second advantage arises in the modelling of material behaviour. The behaviour predicted by the peridynamic theory in the case of small wavelengths is quite different from what is predicted by the conventional theory. Especially, the peridynamic theory may imply nonlinear dispersion relations. In contrast, the conventional theory of elasticity predicts linear dispersion curves corresponding to a constant phase velocity. The (nonlinear) dispersion curves can, in principle, be determined by experiments (cf. GRAFF [4]). The kernel of the IDE (1.1) can then be constructed from the dispersion relation. The resulting mechanical model contains more information about the material behaviour than it can be expressed in conventional local models.

In the case of a homogeneous, infinite bar, described by the IDE (1.5), a dispersion analysis yields the angular frequency ω as a function of the wavenumber k,

$$\omega(k) = \left(\frac{1}{\rho_0} \left(\gamma - \mathcal{F}[C(z)](k) \right) \right)^{1/2} = \left(\int_{-\infty}^{\infty} [1 - \cos(kz)] \frac{C(z)}{\rho_0} \, \mathrm{d}z \right)^{1/2}, \qquad (2.2)$$

$$\gamma := \mathcal{F}[C(z)](0) = \int_{-\infty}^{\infty} C(z) \, \mathrm{d}z \,,$$

where $\mathcal{F}$ denotes the FOURIER transformation with respect to space. Note that $C(-z) = C(z)$, and so $\omega(-k) = \omega(k)$. The dispersion relation can be used to define the GREEN function

$$g(x,t) = \mathcal{F}^{-1} \left[\frac{\sin(\omega(k)\,t)}{\omega(k)} \right](x,t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \cos(kx) \frac{\sin(\omega(k)\,t)}{\omega(k)} \, \mathrm{d}k \,. \qquad (2.3)$$

The solution to (1.5) is then found by convolution,

$$u(x,t) = \int_{-\infty}^{\infty} u_0(x - \hat{x}) \partial_t g(\hat{x}, t) \, \mathrm{d}\hat{x} + \int_{-\infty}^{\infty} v_0(x - \hat{x}) g(\hat{x}, t) \, \mathrm{d}\hat{x}$$

$$+ \int_0^t \int_{-\infty}^{\infty} \frac{h(x - \hat{x}, t - \hat{t})}{\rho_0} g(\hat{x}, \hat{t}) \, \mathrm{d}\hat{x} \, \mathrm{d}\hat{t} \,, \qquad (2.4)$$

which holds in the distributional sense.

On the other hand, the dispersion relation (2.2) can be used to determine the micromodulus function C for a given or experimentally determined dispersion relation $\omega = \omega(k)$. As a first example, we assume that, within the relevant range of wavelengths, the measured phase velocity $v_p(k) = \omega(k)/k$ is constant such that $v_p(k) \equiv c_0$, where c_0 denotes the velocity of sound. This corresponds to the classical linear elasticity theory with a phase velocity that is independent of wavelength. The equation of motion is then given by the wave equation

$$\rho_0 \partial_t^2 u(x,t) = E \partial_x^2 u(x,t) + h(x,t) \qquad (2.5)$$

with YOUNG's modulus $E = \rho_0 c_0^2$, which is equivalent to (1.5) with

$$C(z) = \mathcal{F}^{-1} \left[\gamma - \rho_0 \omega(k)^2 \right](z) = \gamma \delta(z) + E \delta''(z) \,,$$

where $\delta = \delta(z)$ denotes DIRAC's δ-distribution. In this case, the GREEN function (2.3) is given by

$$g(x,t) = \frac{1}{2c_0} \left(H(x + c_0 t) - H(x - c_0 t) \right),$$

where $H = H(z)$ denotes HEAVISIDE's jump function that is zero for negative and one for positive arguments. The solution (2.4) of the IDE (1.5) then reduces to the D'ALEMBERT solution of the wave equation.

From an augmented model incorporating lateral contraction, the phase velocity

$$v_p(k) = \frac{c_0}{\sqrt{1 + (kr\nu)^2}}$$

results. Here, ν is the POISSON number and $r^2 = J/A$ is the second moment J devided by the cross section area A. The equation of motion here reads as

$$\partial_t^2 u(x,t) = c_0^2 \partial_x^2 u(x,t) + (r\nu)^2 \, \partial_t^2 \partial_x^2 u(x,t) \,. \tag{2.6}$$

Taking into account the additional inertial effect, the improved theory results in a dispersive system extending the range of admissible wavelengths compared to the conventional theory of elasticity where $\nu = 0$. For a detailed discussion, we refer to GRAFF [4, p. 121]. However, here we take the point of view that v_p is given (e. g. by the interpolation of experimental data) and the corresponding dynamical model (2.6) is not known in advanvce. The equation (2.2) can then be used to find the micromodulus function C via $\omega(k) = v_p(k)\,k$ and the experimentally determined v_p. It follows

$$C(z) = \mathcal{F}^{-1} \left[\gamma - \rho_0 (v_p(k)k)^2 \right](z) = \gamma \delta(z) + \frac{\rho_0 c_0^2}{2r^3 \nu^3} \exp \left(-\frac{|z|}{r\nu} \right).$$

So the peridynamic equation of motion reads as

$$\partial_t^2 u(x,t) = \frac{c_0^2}{2r^3 \nu^3} \int_{-\infty}^{\infty} \exp \left(-\frac{|x - \xi|}{r\nu} \right) u(\xi,t) \, \mathrm{d}\xi - \left(\frac{c_0}{r\nu} \right)^2 u(x,t) \,, \tag{2.7}$$

since

$$\frac{\rho_0 c_0^2}{2r^3 \nu^3} \int_{-\infty}^{\infty} \exp \left(-\frac{|z|}{r\nu} \right) \mathrm{d}z = \left(\frac{c_0}{r\nu} \right)^2 \,.$$

Indeed, one can show that a smooth, bounded solution to the IDE (2.7) is also a solution to the partial differential equation (2.6) and vice versa, so that both equations are equivalent in the class of sufficiently smooth functions (cf. also TRICOMI [9, p. 162]).

These two examples suggest that the *same* peridynamic equation of motion (1.5) can be used to describe the material behaviour at *different* length scales just by using appropriate micromodulus functions C. It, therefore, seems to be promising to model an even more complicated material behaviour by means of the peridynamic theory.

3 Mathematical analysis

As usual, we denote by $\mathcal{C}$ the space of continuous functions, by $\mathcal{C}_b$ the space of bounded continuous functions, by L^p ($1 \leq p < \infty$) the space of LEBESGUE-measurable functions u such that $|u|^p$ is LEBESGUE-integrable and by L^∞ the space of essentially bounded LEBESGUE-measurable functions. The canonical norm in a normed function space X is denoted by $\| \cdot \|_X$. Moreover, let $\mathcal{C}^m([0,T];X)$ with $m \in \mathbb{N}$ be the space of m-times continuously differentiable abstract functions $u : [0,T] \to X$ with norm

$$\|u\|_{\mathcal{C}^m([0,T];X)} = \max_{t \in [0,T]} \sum_{j=0}^{m} \left\| \frac{\mathrm{d}^m u(t)}{\mathrm{d}t^m} \right\|_X .$$

We also write $\mathcal{C}([0,T];X)$ if $m = 0$. The function space $L^1(0,T;X)$ consists of BOCHNER-integrable abstract functions $u : [0,T] \to X$ such that $t \mapsto \|u(t)\|_X$ is LEBESGUE-integrable and is equipped with the norm

$$\|u\|_{L^1(0,T;X)} = \int_0^T \|u(t)\| \, \mathrm{d}t .$$

Unfortunately, we cannot apply the HILBERT-SCHMIDT theory as the integral operator might be of convolution type and the solutions to (1.1) we have in mind are not integrable over the whole line $(-\infty, \infty)$.

For the kernel k, we shall assume

(H1) $k \in \mathcal{C}(\mathbb{R} \times \mathbb{R})$ with $k_0 := \sup\limits_{x \in \mathbb{R}} \int_{-\infty}^{\infty} |k(x,\xi)| \, \mathrm{d}\xi < \infty$;

(H2) for all $x \in \mathbb{R}$ and $\varepsilon > 0$ there is a $\delta > 0$ such that for all $y \in \mathbb{R}$

$$|x - y| < \delta \quad \text{implies} \quad \int_{-\infty}^{\infty} |k(x,\xi) - k(y,\xi)| \, \mathrm{d}\xi < \varepsilon .$$

Note that, for convolution operators, (H1) is fulfilled if $\tilde{k} \in \mathcal{C}(\mathbb{R}) \cap L^1(\mathbb{R})$. We then have $k_0 = \|\tilde{k}\|_{L^1(\mathbb{R})}$. Assumption (H2) does not follow from the continuity of k as the domain is unbounded. However, it is fulfilled if k possesses a partial derivative $k_x = k_x(x,\xi)$ such that for all $x \in \mathbb{R}$

$$\sup_{x \in \mathbb{R}} \int_{-\infty}^{\infty} |k_x(x,\xi)| \, \mathrm{d}\xi < \infty ,$$

or if k has compact support on $\mathbb{R} \times \mathbb{R}$ (which cannot be the case for convolution operators).

Example 3.1 For

$$\tilde{k}(z) = \begin{cases} \dfrac{\sin z - z \cos z}{z^3} & \text{if } z \neq 0 \\[2mm] \dfrac{1}{3} & \text{if } z = 0 \end{cases} , \quad k(x,\xi) = \tilde{k}(x - \xi) ,$$

the assumptions (H1) and (H2) are fulfilled. Moreover,

$$c(x) \equiv - \int_{-\infty}^{\infty} \tilde{k}(z)\, \mathrm{d}z = -\pi \,,$$

see also Example 4.2 in Section 4.   ∎

Let $c \in L^{\infty}(\mathbb{R})$. For functions $u = u(x) \in L^{\infty}(\mathbb{R})$, we define the (autonomous) operator A via

$$(Au)(x) := \int_{-\infty}^{\infty} k(x,\xi)u(\xi)\, \mathrm{d}\xi + c(x)u(x)\,, \quad x \in \mathbb{R}\,. \qquad (3.1)$$

Due to (H1), the operator A maps into $L^{\infty}(\mathbb{R})$ and is linear and bounded with

$$\|Au\|_{L^{\infty}(\mathbb{R})} \leq \alpha \, \|u\|_{L^{\infty}(\mathbb{R})}\,, \quad \alpha := k_0 + \|c\|_{L^{\infty}(\mathbb{R})}\,.$$

We may write A as the sum of the integral and the multiplication operator, such that

$$A = K + C\,, \text{ where } (Ku)(x) := \int_{-\infty}^{\infty} k(x,\xi)u(\xi)\, \mathrm{d}\xi\,, \ (Cu)(x) := c(x)u(x)\,, \ x \in \mathbb{R}\,.$$

So A is a stationary BARBASHIN operator (cf. APPELL *et al.* [1]).

Proposition 3.1 *Under the assumptions (H1) and (H2), the integral operator K maps $u \in L^{\infty}(\mathbb{R})$ to the bounded continuous function $Ku \in \mathcal{C}_b(\mathbb{R})$.*

Let c be continuous. If $u \in L^{\infty}(\mathbb{R})$ is continuous then Au is continuous, too. If $u \in L^{\infty}(\mathbb{R})$ is a piecewise continuous function with a jump at $\hat{x}$ of height

$$[\![u(\hat{x})]\!] := \lim_{x \searrow \hat{x}} u(x) - \lim_{x \nearrow \hat{x}} u(x)$$

then Au is again piecewise continuous with a jump at $\hat{x}$ of height

$$[\![(Au)(\hat{x})]\!] = c(\hat{x})\, [\![u(\hat{x})]\!]\,.$$

Proof Let $u \in L^{\infty}(\mathbb{R})$ be arbitrary. We show that Ku is continuous on $\mathbb{R}$. For $x, y \in \mathbb{R}$, we have

$$|(Ku)(x) - (Ku)(y)| = \left| \int_{-\infty}^{\infty} (k(x,\xi) - k(y,\xi))\, u(\xi)\, \mathrm{d}\xi \right|$$

$$\leq \int_{-\infty}^{\infty} |k(x,\xi) - k(y,\xi)|\, \mathrm{d}\xi\, \|u\|_{L^{\infty}(\mathbb{R})}\,.$$

Because of (H1), it holds

$$\int_{-\infty}^{\infty} |k(x,\xi) - k(y,\xi)|\, \mathrm{d}\xi \leq 2k_0\,,$$

so the integral converges for all $x, y \in \mathbb{R}$. The continuity of Ku follows from (H2). Moreover, we find from (H1) that

$$|(Ku)(x)| \leq \int_{\infty}^{\infty} |k(x, \xi)| \, d\xi \, \|u\|_{L^{\infty}(\mathbb{R})} \leq k_0 \, \|u\|_{L^{\infty}(\mathbb{R})}$$

for all $x \in \mathbb{R}$, so Ku is bounded.

If c and u are continuous then cu is continuous, too. Hence $Au = Ku + Cu$ is continuous. If c is continuous and u has a jump at $\hat{x}$ then Ku is continuous at $\hat{x}$ and $(Cu)(x) = c(x)u(x)$ has a jump at $\hat{x}$ of height $c(\hat{x}) \llbracket u(\hat{x}) \rrbracket$. Since $Au = Ku + Cu$, the assertion follows. ∎

Denoting by $u = u(t)$ and $b = b(t)$ the abstract functions with values in $L^{\infty}(\mathbb{R})$ that correspond to $u = u(x,t)$ and $b = b(x,t)$, respectively, we may consider the evolutionary equation

$$\ddot{u}(t) = Au(t) + b(t), \quad t \in (0, T), \tag{3.2}$$

instead of (1.1), where $\ddot{u}$ is the second derivative of $u : [0, T] \to L^{\infty}(\mathbb{R})$.

On the product space $L^{\infty}(\mathbb{R}) \times L^{\infty}(\mathbb{R})$, equipped with the norm

$$\left\| (u, v)^{\mathsf{T}} \right\| := \max \left\{ \|u\|_{L^{\infty}(\mathbb{R})}, \|v\|_{L^{\infty}(\mathbb{R})} \right\},$$

we can now define the operator

$$\mathcal{A} := \begin{pmatrix} 0 & I \\ A & 0 \end{pmatrix}, \quad \mathcal{A} \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} u \\ Au \end{pmatrix},$$

where I denotes the identity in $L^{\infty}(\mathbb{R})$. The operator $\mathcal{A} : L^{\infty}(\mathbb{R})^2 \to L^{\infty}(\mathbb{R})^2$ is linear and bounded with

$$\left\| \mathcal{A} \begin{pmatrix} u \\ v \end{pmatrix} \right\| \leq \hat{\alpha} \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|, \quad \hat{\alpha} := \max\{1, \alpha\}.$$

With $v := \dot{u}$, equation (3.2) is equivalent to the first-order operator-differential equation

$$\frac{\mathrm{d}}{\mathrm{d}t} \begin{pmatrix} u(t) \\ v(t) \end{pmatrix} = \mathcal{A} \begin{pmatrix} u(t) \\ v(t) \end{pmatrix} + \begin{pmatrix} 0 \\ b(t) \end{pmatrix}, \quad t \in (0, T). \tag{3.3}$$

It immediately follows from standard arguments and DUHAMEL's principle

Proposition 3.2 *Under the assumption (H1), the operator $\mathcal{A} : L^{\infty}(\mathbb{R})^2 \to L^{\infty}(\mathbb{R})^2$ generates the uniformly continuous semigroup $\{\mathrm{e}^{t\mathcal{A}}\}_{t \geq 0}$ with*

$$\mathrm{e}^{t\mathcal{A}} = \begin{pmatrix} \cosh(t\sqrt{A}) & \sqrt{A}^{-1} \sinh(t\sqrt{A}) \\ \sqrt{A} \sinh(t\sqrt{A}) & \cosh(t\sqrt{A}) \end{pmatrix} = \begin{pmatrix} \sum\limits_{n=0}^{\infty} \frac{t^{2n} A^n}{(2n)!} & \sum\limits_{n=0}^{\infty} \frac{t^{2n+1} A^n}{(2n+1)!} \\ \sum\limits_{n=0}^{\infty} \frac{t^{2n+1} A^{n+1}}{(2n+1)!} & \sum\limits_{n=0}^{\infty} \frac{t^{2n} A^n}{(2n)!} \end{pmatrix}. \tag{3.4}$$

Let $b \in L^1(0,T; L^\infty(\mathbb{R}))$. Then

$$
\begin{pmatrix} u(t) \\ v(t) \end{pmatrix} = \mathrm{e}^{t\mathcal{A}} \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} + \int_0^t \mathrm{e}^{(t-s)\mathcal{A}} \begin{pmatrix} 0 \\ b(s) \end{pmatrix} \mathrm{d}s \,, \quad t \in (0,T) \,, \tag{3.5}
$$

is the unique mild solution to (3.3) with the initial values $u(0) = u_0 \in L^\infty(\mathbb{R})$ and $v(0) = v_0 \in L^\infty(\mathbb{R})$. If $b \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$ then $\ddot{u} \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$.

Note that $\sqrt{A}$ and $\sqrt{A}^{-1}$ is only a symbolic notation as A need not to be invertible but $\cosh(t\sqrt{A})$, $\sqrt{A}^{-1}\sinh(t\sqrt{A})$, and $\sqrt{A}\sinh(t\sqrt{A})$ are well defined as series of potencies of A as in (3.4).

Theorem 3.1 *Let $b \in L^1(0,T; L^\infty(\mathbb{R}))$ and assume (H1). Then*

$$
u(t) = \cosh(t\sqrt{A})\, u_0 + \sqrt{A}^{-1} \sinh(t\sqrt{A})\, v_0 + \sqrt{A}^{-1} \int_0^t \sinh((t-s)\sqrt{A})\, b(s)\, \mathrm{d}s \tag{3.6}
$$

is the unique mild solution to (3.2) with the initial values $u(0) = u_0 \in L^\infty(\mathbb{R})$ and $\dot{u}(0) = v_0 \in L^\infty(\mathbb{R})$ and lies in $\mathcal{C}([0,T]; L^\infty(\mathbb{R}))$. Moreover, the a priori estimate

$$
\|u(t)\|_{L^\infty(\mathbb{R})} \leq \cosh(t\sqrt{\alpha})\, \|u_0\|_{L^\infty(\mathbb{R})} + \sqrt{\alpha}^{-1} \sinh(t\sqrt{\alpha})\, \|v_0\|_{L^\infty(\mathbb{R})} +
$$

$$
+ \sqrt{\alpha}^{-1} \int_0^t \sinh((t-s)\sqrt{\alpha})\, \|b(s)\|_{L^\infty(\mathbb{R})}\, \mathrm{d}s \tag{3.7}
$$

holds for $t \in (0,T)$. If $b \in \mathcal{C}^m([0,T]; L^\infty(\mathbb{R}))$ ($m \in \mathbb{N}$) then $u \in \mathcal{C}^{m+2}([0,T]; L^\infty(\mathbb{R}))$. If b is constant in time, then

$$
u(t) = \cosh(t\sqrt{A})\, u_0 + \sqrt{A}^{-1} \sinh(t\sqrt{A})\, v_0 + A^{-1}\left(\cosh(t\sqrt{A}) - I\right) b \,. \tag{3.8}
$$

Proof Existence and uniqueness follow directly from Proposition 3.2. The estimate (3.7) follows from the boundedness of A and properties of the BOCHNER integral. The representation (3.6) results from (3.4) and (3.5). The regularity is a direct consequence of the differential equation (3.2) and the linearity of the time-independent operator A. Carrying out the integration gives the representation for stationary b with the symbolic notation

$$
A^{-1}\left(\cosh(t\sqrt{A}) - I\right) := \sum_{n=1}^{\infty} \frac{t^{2n} A^{n-1}}{(2n)!} \,.
$$

∎

In virtue of the linearity of the problem, the estimate (3.7) also proves stability with respect to the data u_0, v_0, and b.

Theorem 3.2 *Let $b \in L^1(0,T; L^\infty(\mathbb{R}))$ and let, for arbitrary $\varepsilon > 0$, k and k_ε be kernels satisfying (H1) and $c, c_\varepsilon \in L^\infty(\mathbb{R})$ such that*

$$
\sup_{x \in \mathbb{R}} \int_{-\infty}^{\infty} |k(x,\xi) - k_\varepsilon(x,\xi)|\, \mathrm{d}\xi + \|c - c_\varepsilon\|_{L^\infty(\mathbb{R})} < \varepsilon \,.
$$

For the unique mild solutions $u, u_\varepsilon \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$ to equation (3.2) with k, c and k_ε, c_ε, respectively, and with the initial values $u(0) = u_\varepsilon(0) = u_0 \in L^\infty(\mathbb{R})$ and $\dot{u}(0) = \dot{u}_\varepsilon(0) = v_0 \in L^\infty(\mathbb{R})$, the estimate

$$\|u(t) - u_\varepsilon(t)\|_{L^\infty(\mathbb{R})} \leq \varepsilon \sqrt{\alpha + \varepsilon}^{-1} \int_0^t \sinh((t-s)\sqrt{\alpha + \varepsilon}) \, \|u(s)\|_{L^\infty(\mathbb{R})} \, \mathrm{d}s \quad (3.9)$$

holds true for all $t \in (0,T)$.

Proof Let A_ε be the operator (3.1) corresponding to k_ε and c_ε. For the difference $w_\varepsilon := u - u_\varepsilon$, it follows

$$\ddot{w}_\varepsilon = A_\varepsilon w_\varepsilon + (A - A_\varepsilon)\, u$$

with $w_\varepsilon(0) = \dot{w}_\varepsilon(0) = 0$. Note that $(A - A_\varepsilon)\, u \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$ since $u \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$ and $A - A_\varepsilon$ is a linear bounded operator in $L^\infty(\mathbb{R})$. Due to Theorem 3.1, now applied on the foregoing initial-value problem with the unknown w_ε and the inhomogeneity $(A - A_\varepsilon)\, u$, and because of

$$\|A_\varepsilon v\|_{L^\infty(\mathbb{R})} \leq \|Av\|_{L^\infty(\mathbb{R})} + \|Av - A_\varepsilon v\|_{L^\infty(\mathbb{R})} \leq \alpha \, \|v\|_{L^\infty(\mathbb{R})} + \varepsilon \, \|v\|_{L^\infty(\mathbb{R})}$$

for all $v \in L^\infty(\mathbb{R})$, we find

$$\|w_\varepsilon(t)\|_{L^\infty(\mathbb{R})} \leq \sqrt{\alpha + \varepsilon}^{-1} \int_0^t \sinh((t-s)\sqrt{\alpha + \varepsilon}) \, \|(A - A_\varepsilon)\, u(s)\|_{L^\infty(\mathbb{R})} \, \mathrm{d}s$$

and thus the assertion. ∎

Estimate (3.9), together with (3.7), justifies the idea of measuring the dispersion relation and the experimental determination of the micromodulus function, which then gives the kernel k and the coefficient c.

Corollary 3.1 *Let $b \in L^1(0,T; L^\infty(\mathbb{R}))$ and assume (H1) and (H2) with $c \in \mathcal{C}_b(\mathbb{R})$. If u_0, v_0 and $b(t)$ $(t \in [0,T])$ are bounded and continuous then the solution u from Theorem 3.1, given by (3.6), is in $\mathcal{C}([0,T] \times \mathbb{R})$. If, in addition, $b \in \mathcal{C}([0,T]; \mathcal{C}_b(\mathbb{R}))$ then u is the unique classical solution to the initial-value problem for (1.1). If u_0, v_0 or the stationary b is bounded and piecewise continuous with a jump at $\hat{x}$ then the solution u is also piecewise continuous with respect to x and, for all times $t \in [0,T]$, the jump remains at $\hat{x}$ with*

$$[\![u(\hat{x}, t)]\!] = \cosh(t\sqrt{c(\hat{x})}) \, [\![u_0(\hat{x})]\!] + \sqrt{c(\hat{x})}^{-1} \sinh(t\sqrt{c(\hat{x})}) \, [\![v_0(\hat{x})]\!]$$
$$+ c(\hat{x})^{-1} \left(\cosh(t\sqrt{c(\hat{x})}) - 1 \right) [\![b(\hat{x})]\!] \quad (3.10)$$

and no other jumps are generated. If $c \equiv 0$ then

$$[\![u(\hat{x}, t)]\!] = [\![u_0(\hat{x})]\!] + t \, [\![v_0(\hat{x})]\!] + \frac{1}{2} t^2 \, [\![b(\hat{x})]\!] \ .$$

Proof From Proposition 3.1, we know that A maps continuous functions into continuous functions. Potencies of A do so, too. The solution $u \in \mathcal{C}([0,T]; L^\infty(\mathbb{R}))$ from Theorem 3.1 is, therefore, continuous with respect to x if u_0, v_0 and $b(t)$ $(t \in [0,T])$

are continuous. It follows the continuity on $[0, T] \times \mathbb{R}$. If $b \in \mathcal{C}([0, T]; \mathcal{C}_b(\mathbb{R}))$ then $u \in \mathcal{C}^2([0, T]; \mathcal{C}_b(\mathbb{R}))$ and u solves (1.1) in the classical sense. Moreover, (1.1) possesses at most one solution since any classical solution is also a mild solution but the mild solution is unique. The jump relations immediately follow from Proposition 3.1 and the representation (3.8). ∎

Example 3.2 Consider the Riemann-like problem with $c(x) \equiv c \in \mathbb{R}$, $u_0(x) = u_l H(-x) + u_r H(x)$ ($u_l, u_r \in \mathbb{R}$ given), $v_0(x) \equiv 0$, and $b(x, t) \equiv 0$, where H denotes again the Heaviside function. Then

$$u(x, t) = \sum_{n=0}^{\infty} \frac{t^{2n}}{(2n)!} (A^n u_0)(x)$$

with

$$[\![u(0, t)]\!] = (u_r - u_l) \sum_{n=0}^{\infty} \frac{t^{2n} c^n}{(2n)!} = (u_r - u_l) \cdot \begin{cases} \cosh(t\sqrt{c}) & \text{if } c > 0 \\ 1 & \text{if } c = 0 \\ \cos(t\sqrt{-c}) & \text{if } c < 0 \end{cases}.$$

∎

Note that a jump in the initial velocity v_0 produces a jump in the displacement field $u = u(x, t)$ for $t > 0$ even if the initial displacement u_0 is continuous. This is shown in

Example 3.3 Consider the Riemann-like problem with $c(x) \equiv c \in \mathbb{R}$, $u_0(x) \equiv 0$, $v_0(x) = v_l H(-x) + v_r H(x)$ ($v_l, v_r \in \mathbb{R}$ given), and $b(x, t) \equiv 0$. Then

$$u(x, t) = \sum_{n=0}^{\infty} \frac{t^{2n+1}}{(2n+1)!} (A^n v_0)(x)$$

with

$$[\![u(0, t)]\!] = (v_r - v_l) \sum_{n=0}^{\infty} \frac{t^{2n+1} c^n}{(2n+1)!} = (v_r - v_l) \cdot \begin{cases} \frac{1}{\sqrt{c}} \sinh(t\sqrt{c}) & \text{if } c > 0 \\ t & \text{if } c = 0 \\ \frac{1}{\sqrt{-c}} \sin(t\sqrt{-c}) & \text{if } c < 0 \end{cases}.$$

∎

4   Numerical approximation and examples

For the numerical solution of (1.1), we suggest the following method. We assume that u_0, v_0, and $b(\cdot, t)$ ($t \in [0, T]$) are bounded and piecewise continuous and that for any fixed x the mapping $t \mapsto b(x, t)$ is continuous. Let

$$-\infty < s_1 < s_2 < \cdots < s_m < \infty$$

be the abscissae where u_0, v_0 or $b(\cdot, t)$ has a jump discontinuity. The integral operator K may then be represented as

$$(Ku)(x) = \int_{-\infty}^{s_1} k(x, \xi) u(\xi) \, \mathrm{d}\xi + \int_{s_1}^{s_2} k(x, \xi) u(\xi) \, \mathrm{d}\xi + \cdots + \int_{s_m}^{\infty} k(x, \xi) u(\xi) \, \mathrm{d}\xi$$

$$=: (K_0 u)(x) + (K_1 u)(x) + \cdots + (K_m u)(x) \, .$$

If $m = 0$ then $K \equiv K_0$. For each integral operator K_i $(i = 0, 1, \ldots, m)$, we consider a sequence of quadrature formulae

$$(K_i u)(x) \approx \sum_{j=0}^{N_i} \sigma_{i,j}^{(N_i)} k\left(x, \xi_{i,j}^{(N_i)}\right) u\left(\xi_{i,j}^{(N_i)}\right) =: \left(K_i^{(N_i)} u\right)(x) \, ,$$

where $N_i \in \mathbb{N}$, the weights $\sigma_{i,j}^{(N_i)}$, and the quadrature points $\xi_{i,j}^{(N_i)}$ are given. Note that $\xi_{i,N_i}^{(N_i)}$ and $\xi_{i+1,0}^{(N_{i+1})}$ might coincide. For convenience, we introduce another notation:

$$N := \sum_{i=0}^{m} (N_i + 1) - 1 \, , \quad x_n^{(N)} := \xi_{i,j}^{(N_i)} \, , \quad \sigma_n^{(N)} := \sigma_{i,j}^{(N_i)} \quad \text{with} \quad n = \sum_{\nu=0}^{i-1} (N_\nu + 1) + j \, .$$

We shall assume

$$x_0^{(N)} \le x_1^{(N)} \le \cdots \le x_N^{(N)} \, .$$

The integral operator K is thus approximated by the composite quadrature

$$(Ku)(x) \approx \sum_{n=0}^{N} \sigma_n^{(N)} k\left(x, x_n^{(N)}\right) u\left(x_n^{(N)}\right) =: \left(K^{(N)} u\right)(x) \, . \tag{4.1}$$

Regarding the IDE (1.1), remember that its solution $u = u(x, t)$ possesses only jumps at the abscissae $s_1, \ldots, s_m$, which justifies the composite quadrature suggested. We are now looking for functions $U_l^{(N)} = U_l^{(N)}(t)$ approximating $t \mapsto u(x_l^{(N)}, t)$ $(l = 0, 1, \ldots, N)$ that fulfill the initial-value problem

$$\frac{\mathrm{d}^2 U_l^{(N)}(t)}{\mathrm{d}t^2} = \sum_{n=0}^{N} \sigma_n^{(N)} k\left(x_l^{(N)}, x_n^{(N)}\right) U_n^{(N)}(t) + c\left(x_l^{(N)}\right) U_l^{(N)}(t) + b\left(x_l^{(N)}, t\right) \, ,$$

$$l = 0, 1, \ldots, N \, , \ t \in (0, T) \, , \tag{4.2}$$

with

$$U_l^{(N)}(0) = u_0\left(x_l^{(N)}\right) \, , \quad \frac{\mathrm{d}U_l^{(N)}(0)}{\mathrm{d}t} = v_0\left(x_l^{(N)}\right) \, , \quad l = 0, 1, \ldots, N \, . \tag{4.3}$$

As this is a linear system, there is a unique solution $U^{(N)} := \left(U_0^{(N)}, \ldots, U_N^{(N)}\right)^{\mathsf{T}}$.

In order to demonstrate the numerical method presented we consider two examples for the solution to the initial-value problem for the IDE (1.5) of the homogeneous

bar. For both examples, analytical solutions are at hand, which allows us to validate our numerical results and also to discuss the limits of the method suggested. The first example shows the response to continuous initial conditions while the second example is concerned with discontinuous initial conditions: the velocity field involves jump discontinuities and the initial displacement field is taken to be zero.

Example 4.1 (GAUSSIAN **initial displacement**) We consider (1.5) for the initial conditions and micromodulus function

$$u_0(x) = U \mathrm{e}^{-(x/L)^2}, \quad v_0(x) \equiv 0, \quad C(x) = \frac{4E}{\ell^3 \sqrt{\pi}} \, \mathrm{e}^{-(x/\ell)^2}$$

with YOUNG's modulus E, a length-scale parameter $\ell > 0$, and $U \in \mathbb{R}$, $L > 0$ given. For $\ell \to 0$, equation (1.5) then becomes the wave equation of local elasticity theory

$$\rho_0 \partial_t^2 u(x,t) = E \partial_x^2 u(x,t) + h(x,t) \,. \tag{4.4}$$

So ℓ represents the degree of non-locality. In the following, let the right-hand side h be zero. With the normalisation

$$\hat{x} := \frac{x}{L}, \quad \hat{t} := \frac{c_0 t}{L} \quad \text{with} \quad c_0 := \sqrt{\frac{E}{\rho_0}}, \quad \hat{u}(\hat{x}, \hat{t}) := \frac{u(x,t)}{U} \,,$$

the equation of motion (1.5) can be rewritten in dimensionless form (1.1) with the convolution kernel $\tilde{k}$ and the constant coefficient c given by

$$\tilde{k}(\hat{z}) := \frac{L^3}{E} \, C(z) = \frac{4}{\sqrt{\pi}} \left(\frac{L}{\ell} \right)^3 \mathrm{e}^{-(\hat{z}L/\ell)^2}, \quad c(\hat{x}) := -\int_{-\infty}^{\infty} \tilde{k}(\hat{z}) \mathrm{d}\hat{z} = -\left(\frac{2L}{\ell} \right)^2 \,.$$

The exact solution of this initial value problem is given by

$$\hat{u}(\hat{x}, \hat{t}) = \frac{2}{\sqrt{\pi}} \int_0^{\infty} \cos\left(2\alpha\hat{x}\right) \mathrm{e}^{-\alpha^2} \cos\left(\frac{2L\hat{t}}{\ell} \sqrt{1 - \mathrm{e}^{-(\alpha\ell/L)^2}} \right) \mathrm{d}\alpha \,, \tag{4.5}$$

cf. WECKNER & ABEYARATNE [10]. Expanding (4.5) in a TAYLOR series around $\ell/L = 0$, one obtains in the limit $\ell/L \to 0$ the D'ALEMBERT solution to (4.4)

$$(\hat{x}, \hat{t}) \mapsto U \frac{\mathrm{e}^{-(\hat{x}-\hat{t})^2} + \mathrm{e}^{-(\hat{x}+\hat{t})^2}}{2} \,.$$

In what follows, we omit the hat and deal only with the dimensionless quantities.

We apply the numerical method suggested with $m = 0$ as there is no discontinuity in the data. The numerical integration is based upon the GAUSS-HERMITE quadrature

$$\int_{-\infty}^{\infty} \mathrm{e}^{-\xi^2} \Phi(\xi) \mathrm{d}\xi \approx \sum_{j=0}^{N} \gamma_j^{(N)} \Phi(\xi_j^{(N)}) \,,$$

where $\xi_0^{(N)} < \xi_1^{(N)} < \cdots < \xi_N^{(N)}$ are the roots of the HERMITE polynomial

$$H_{N+1}(\xi) := (-1)^{N+1} \mathrm{e}^{\xi^2} \frac{\mathrm{d}^{N+1}}{\mathrm{d}\xi^{N+1}} \left(\mathrm{e}^{-\xi^2} \right)$$

and the weights $\gamma_j^{(N)} > 0$ $(j = 0, 1, \ldots, N)$ are given by

$$\gamma_j^{(N)} := \int_{-\infty}^{\infty} \mathrm{e}^{-\xi^2} L_j^{(N)}(\xi)\mathrm{d}\xi\,, \quad L_j^{(N)}(\xi) := \prod_{\substack{i=0 \\ i \neq j}}^{N} \frac{\xi - \xi_i^{(N)}}{\xi_j^{(N)} - \xi_i^{(N)}}\,. \tag{4.6}$$

The GAUSS-HERMITE quadrature is exact for polynomials $\Phi = \Phi(\xi)$ of highest degree $2N + 1$.

The approximate operator $K^{(N)}$ is now given by (4.1) with

$$\sigma_j^{(N)} := \gamma_j^{(N)} \exp\left(\left(\xi_j^{(N)}\right)^2\right)\,, \quad x_j^{(N)} := \xi_j^{(N)} \quad (j = 0, 1, \ldots, N)\,,$$

and we have to solve the initial-value problem (4.2), (4.3).

We choose $N = 48$ and $\ell/L = 3/4$. The location of the roots $\xi_j^{(48)}$ $(j = 0, 1, \ldots, 48)$ of the HERMITE polynomial H_{49} is shown in Figure 1.
Fig. 1: Roots of the HERMITE polynomial H_{49}

The numerical time integration of (4.2) has been carried out with the software MATHEMATICA 4.0 that uses the Livermore Solver LSODE. The results are compared with the exact solution given by (4.5). (In order to evaluate (4.5), we again use MATHEMATICA. For the following discussion, we assume that the spatial numerical integration of (4.5) and the temporal numerical integration of (4.2) are exact within the resolution of the line thickness. This can be verified by increasing the working precision such that the numerical and graphical results presented do not change.)

The classical wave solution and the peridynamic solution is presented in Figure 2.

Fig. 2: Exact peridynamic (left) and wave (right) solution for Example 4.1
Figure 3 shows the numerical solution.

Fig. 3: Numerical peridynamic solution for Example 4.1

It turns out that the numerical results agree quite well with the analytical results for all points $x \in \left[\xi_0^{(48)} \approx -9.1, \xi_{48}^{(48)} \approx 9.1 \right]$ if we limit the time of observation up to $t < 6$. Increasing the number of integration points extends both the spatial and temporal observation interval. The valid temporal observation period can be also extended if we restrict our attention to points closer to the origin: the computed displacement of the particle located at the origin $0 = \xi_{24}^{(48)}$ is a good approximation until $t \approx 14$. For $t > 14$, however, the results diverge for all points x. In particular, the method presented fails when predicting long-time behaviour. ∎

Example 4.2 (Multiple jump discontinuities in the initial velocity field)
For $s_1 < s_2 < \cdots < s_m$ and $v_0, v_1, \ldots, v_m \in \mathbb{R}$ given, we consider the initial displacement and velocity (see also Figure 4)

$$u_0(x) \equiv 0, \quad v_0(x) = \frac{v_0 + v_m}{2} + \sum_{i=1}^{m} \frac{v_i - v_{i-1}}{2} \ \mathrm{sgn}(x - s_i).$$

Here, sgn is the sign function. The FOURIER transforms are given by

$$\mathcal{F}[u_0](k) \equiv 0, \quad \mathcal{F}[v_0](k) = (v_0 + v_m)\pi\delta(k) - \imath \sum_{i=1}^{m} (v_i - v_{i-1})\frac{\mathrm{e}^{-\imath s_i k}}{k} \,,$$

where $\imath$ denotes the imaginary unit and δ is again DIRAC's δ-distribution. The right-hand side is taken to be zero.
Fig. 4: Initial velocity field involving multiple jump discontinuities

The micromodulus function we wish to investigate reads as

$$C(x) = \frac{2E}{\pi \ell^3} \begin{cases} \dfrac{\sin(\frac{x}{\ell}) - \frac{x}{\ell}\cos(\frac{x}{\ell})}{(\frac{x}{\ell})^3} & \text{if } \dfrac{x}{l} \neq 0 \,, \\[2ex] \dfrac{1}{3} & \text{if } \dfrac{x}{l} = 0 \,. \end{cases}$$

and corresponds to the simple dispersion relation

$$\omega(k) = \frac{c_0}{\ell} \begin{cases} |k\ell| & \text{if } |k\ell| < 1 \,, \\ 1 & \text{if } |k\ell| \geq 1 \,. \end{cases}$$

Again, ℓ denotes a length-scale parameter, which characterises the non-locality, and $c_0 = \sqrt{E/\rho}$. The homogeneous solution for this material with $u_0 \equiv 0$ and arbitrary v_0 is given by

$$u(x,t) = \frac{\sin(c_0 t/\ell)}{c_0/\ell} \, v_0(x) + \frac{1}{2\pi} \int_{-1/\ell}^{+1/\ell} e^{ikx} \mathcal{F}[v_0](k) \left(\frac{\sin(c_0 tk)}{c_0 k} - \frac{\sin(c_0 t/\ell)}{c_0/\ell} \right) dk \,.$$

For the above initial velocity, we obtain

$$\hat{u}(\hat{x}, \hat{t}) = \frac{\hat{v}_0 + \hat{v}_m}{2} \, \hat{t}$$

$$+ \sin(\hat{t}) \sum_{i=1}^{m} \frac{\hat{v}_i - \hat{v}_{i-1}}{2} \left(\operatorname{sgn}(\hat{x} - \hat{s}_i) - \frac{2}{\pi} \sin(\hat{x} - \hat{s}_i) - \frac{2}{\pi} \operatorname{Si}(\hat{x} - \hat{s}_i) \right)$$

$$+ \frac{1}{\pi} \sum_{i=1}^{m} \frac{\hat{v}_i - \hat{v}_{i-1}}{2} \left((\hat{x} - \hat{s}_i + \hat{t}) \operatorname{Si}(\hat{x} - \hat{s}_i + \hat{t}) - (\hat{x} - \hat{s}_i - \hat{t}) \operatorname{Si}(\hat{x} - \hat{s}_i - \hat{t}) \right) ,$$

where

$$\hat{x} := \frac{x}{\ell} \,, \quad \hat{s}_i := \frac{s_i}{\ell} \,, \quad \hat{t} := \frac{c_0 t}{\ell} \,, \quad \hat{v}_i := \frac{v_i}{c_0} \,, \quad \hat{u}(\hat{x}, \hat{t}) := \frac{u(x,t)}{\ell} \,,$$

and $\text{Si}(x) := \int_0^x \xi^{-1} \sin \xi d\xi$ is the integral sine. In the following, we omit the hat and consider only the dimensionless quantities.

Let us assume that $m = 2$ with $s_1 = -1$ and $s_2 = 1$. We then have

$$K^{(N)} = K_0^{(N_0)} + K_1^{(N_1)} + K_2^{(N_2)},$$

where $K_0^{(N_0)}$ is the approximation of the integral over $(-\infty, s_1)$, $K_1^{(N_1)}$ corresponds to (s_1, s_2), and $K_2^{(N_2)}$ corresponds to (s_2, ∞).

For $K_0^{(N_0)}$ and $K_2^{(N_2)}$, we again employ the GAUSS-HERMITE quadrature: Outside the corresponding interval, the integrand is extended by zero and the quadrature points are centred at s_1 and s_2, respectively. For a function $f : (-\infty, s_1) \to \mathbb{R}$, we thus have

$$\int_{-\infty}^{s_1} f(\xi) d\xi \approx K_0^{(N_0)} f := \sum_{j=0}^{N_0} \gamma_j^{(2N_0+1)} \exp\left(\left(\xi_j^{(2N_0+1)}\right)^2\right) f\left(s_1 + \xi_j^{(2N_0+1)}\right),$$

and a similar representation for $K_2^{(N_2)}$, with the roots $\xi_j^{(2N_0+1)}$ of the HERMITE polynomial H_{2N_0+2} and $\gamma_j^{(2N_0+1)}$ given by (4.6). The integral over (s_1, s_2) is approximated by the composite trapezoidal rule with equidistant quadrature points. For simplicity, we take $N_0 = N_2$ and $N_1 = 2(N_0 + 1)$. The system (4.2) then consists of $N + 1 = 4(N_0 + 1) + 1$ equations.

Figure 5 shows the analytical and numerical solution $u = u(x, t)$ at the fixed times $t = 2, 3, 4$ with $v_0 = v_2 = 0$, $v_1 = 0.5$ and $N + 1 = 101$ quadrature points. For the presentation of the numerical solution, we use piecewise cubic interpolation.

Another way to present the results is to look at a fixed particle at $x = 0$ as in Figure 6.

Fig. 6: Numerical (thin lines) compared to analytical (thick lines) results for Example 4.2 at fixed spatial points

Whereas the left figure shows the numerical results for 41 quadrature points, the right one shows the results for 101 quadrature points. As in Example 4.1, one finds that the numerical results are reasonable only for a finite time interval. The more integration points are taken, the longer this time interval becomes. The convergence seems, however, to be rather slow in this example. In the context of fracture mechanics this is of no concern since the long-time behaviour is neither
Fig. 5: Numerical (dashed lines) compared to analytical (thin lines) results for Example 4.2 at fixed times

interesting nor could it be described by the same mathematical model (one would expect nonlinearity, plasticity etc. to play an important rôle here).

The following table shows the CPU-time T_{CPU} needed for the calculation (with an Intel Pentium M 1.4 GHz and 512 MB RAM) with a fixed time interval $[0, 10]$ in dependence of the number $N + 1$ of quadrature points:

$N + 1$ [1]	T_{CPU} [s]
41	92
61	408
81	1244
101	2791
